ELEVENTH EDITION

VOLUME XIV

HUSBAND, properly the "head of a household," but now chiefly used in the sense of a man legally joined by marriage to a woman, his "wife"; the legal relations between them are treated below under HUSBAND AND WIFE. The word appears in O. Eng. as *húsbonda*, answering to the Old Norwegian *húsbóndi*, and means the owner or freeholder of a *hus*, or house. The last part of the word still survives in "bondage" and "bondman," and is derived from *bua*, to dwell, which, like Lat. *colere*, means also to till or cultivate, and to have a household. "Wife," in O. Eng. *wif*, appears in all Teutonic languages except Gothic; cf. Ger. *Weib*, Dutch *wijf*, &c., and meant originally simply a female, "woman" itself being derived from *wifman*, the pronunciation of the plural *wimmen* still preserving the original *i*. Many derivations of "wife" have been given; thus it has been connected with the root of "weave," with the Gothic *waibjan*, to fold or wrap up, referring to the entangling clothes worn by a woman, and also with the root of *vibrare*, to tremble. These are all merely guesses, and the ultimate history of the word is lost. It does not appear outside Teutonic languages. Parallel to "husband" is "housewife," the woman managing a household. The earlier *húswif* was pronounced *hussif*, and this pronunciation survives in the application of the word to a small case containing scissors, needles and pins, cottons, &c. From this form also derives "hussy," now only used in a depreciatory sense of a light, impertinent girl. Beyond the meaning of a husband as a married man, the word appears in connexion with agriculture, in "husbandry" and "husbandman." According to some authorities "husbandman" meant originally in the north of England a holder of a "husbandland," a manorial tenant who held two ox-gangs or virgates, and ranked next below the yeoman (see J. C. Atkinson in *Notes and Queries*, 6th series, vol. xii., and E. Bateson, *History of Northumberland*, ii., 1893). From the idea of the manager of a household, "husband" was in use transferred to the manager of an estate, and the title was held by certain officials, especially in the great trading companies. Thus the "husband" of the East India Company looked after the interests of the company at the custom-house. The word in this sense is practically obsolete, but it still appears in "ship's husband," an agent of the owners of a ship who looks to the proper equipping of the vessel, and her repairs, procures and adjusts freights, keeps the accounts, makes charter-parties and acts generally as manager of the ship's employment. Where such an agent is himself one of the owners of the vessel, the name of "managing owner" is used. The "ship's husband" or "managing owner" must register his name and address at the port of registry (Merchant Shipping Act 1894, § 59). From the use of "husband" for a good and thrifty manager of a household, the verb "to husband" means to economize, to lay up a store, to save.

HUSBAND AND WIFE, LAW RELATING TO. For the modes in which the relation of husband and wife may be constituted and dissolved, see MARRIAGE and DIVORCE. The present article will deal only with the effect of marriage on the legal position of the spouses. The person chiefly affected is the wife, who probably in all political systems becomes subject, in consequence of marriage, to some kind of disability. The most favourable system scarcely leaves her as free as an unmarried woman; and the most unfavourable subjects her absolutely to the authority of her husband. In modern times the effect of marriage on property is perhaps the most important of its consequences, and on this point the laws of different states show wide diversity of principles.

The history of Roman law exhibits a transition from an extreme theory to its opposite. The position of the wife in the earliest Roman household was regulated by the law of *Manus*. She fell under the "hand" of her husband,—became one of his family, along with his sons and daughters, natural or adopted, and his slaves. The dominion which, so far as the children was concerned, was known as the *patria potestas*, was, with reference to the wife, called the *manus*. The subject members of the family, whether wife or children, had, broadly speaking, no rights of their own. If this institution implied the complete subjection of the wife to the husband, it also implied a much closer bond of union between them than we find in the later Roman law. The wife on her husband's death succeeded, like the children, to freedom and a share of the inheritance. *Manus*, however, was not essential to a legal marriage; its restraints were irksome and unpopular, and in course of time it ceased to exist, leaving no equivalent protection of the stability of family life. The later Roman marriage left the spouses comparatively independent of each other. The distance between the two modes of marriage may be estimated by the fact that, while under the former the wife was one of the husband's immediate heirs, under the latter she was called to the inheritance only after his kith and kin had been exhausted, and only in preference to the treasury. It seems doubtful how far she had, during the continuance of marriage, a legal right to enforce aliment from her husband, although if he neglected her she had the unsatisfactory remedy of an easy divorce. The law, in fact, preferred to leave the parties to arrange their mutual rights and obligations by private contracts. Hence the importance of the law of settlements (*Dotes*). The *Dos* and the *Donatio ante nuptias* were settlements by or on behalf of the husband or wife, during the continuance of the marriage, and the law seems to have looked with some jealousy on gifts made by one to the other in any less formal way, as possibly tainted with undue influence. During the marriage the husband had the administration of the property.

The *manus* of the Roman law appears to be only one instance of an institution common to all primitive societies. On the continent of Europe after many centuries, during which local usages were brought under the influence of principles derived from the Roman law, a theory of marriage became established, the leading feature of which is the *community of goods* between husband and wife. Describing the principle as it prevails in France, Story (*Conflict of Laws*, § 130) says: "This community or nuptial partnership (in the absence of any special contract) generally extends to all the movable property of the husband and wife, and to the fruits, income and revenue thereof. . . . It extends also to all immovable property of the husband and wife acquired during the marriage, but not to such immovable property as either possessed at the time of the marriage, or which came to them afterwards by title of succession or by gift. The property thus acquired by this nuptial partnership is liable to the debts of the parties existing at the time of the marriage; to the debts contracted by the husband during the community, or by the wife during the community with the consent of the husband; and to debts contracted for the maintenance of the family. . . . The husband alone is entitled to administer the property of the community, and he may alien, sell or mortgage it without the concurrence of the wife." But he cannot dispose by will of more than his share of the common property, nor can he part with it gratuitously *inter vivos*. The community is dissolved by death (natural or civil), divorce, separation of body or separation of property. On separation of body or of property the wife is entitled to the full control of her movable property, but cannot alien her immovable property, without her husband's consent or legal authority. On the death of either party the property is divided in equal moieties between the survivor and the heirs of the deceased.

Law of England.—The English common law as usual followed its own course in dealing with this subject, and in no department were its rules more entirely insular and independent. The text writers all assumed two fundamental principles, which between them established a system of rights totally unlike that just described. Husband and wife were said to be one person in the eye of the law—*unica persona, quia caro una et sanguis unus.* Hence a man could not grant or give anything to his wife, because she was himself, and if there were any compacts between them before marriage they were dissolved by the union of persons. Hence, too, the old rule of law, now greatly modified, that husband and wife could not be allowed to give evidence against each other, in any trial, civil or criminal. The unity, however, was one-sided only; it was the wife who was merged in the husband, not the husband in the wife. And when the theory did not apply, the disabilities of "coverture" suspended the active exercise of the wife's legal faculties. The old technical phraseology described husband and wife as *baron* and *feme*; the rights of the husband were baronial rights. From one point of view the wife was merged in the husband, from another she was as one of his vassals. A curious example is the immunity of the wife in certain cases from punishment for crime committed in the presence and on the presumed coercion of the husband. "So great a favourite," says Blackstone, "is the female sex of the laws of England."

The application of these principles with reference to the property of the wife, and her capacity to contract, may now be briefly traced.

The *freehold property* of the wife became vested in the husband and herself during the coverture, and he had the management and the profits. If the wife had been in actual possession at any time during the marriage of an estate of inheritance, and if there had been a child of the marriage capable of inheriting, then the husband became entitled on his wife's death to hold the estate for his own life as tenant by the *curtesy of England* (*curialitas*).[1] Beyond this, however, the husband's rights did not extend, and the wife's heir at last succeeded to the inheritance. The wife could not part with her real estate without the concurrence of the husband; and even so she must be examined apart from her husband, to ascertain whether she freely and voluntarily consented to the deed.

With regard to personal property, it passed absolutely at common law to the husband. Specific things in the possession of the wife (*choses* in possession) became the property of the husband at once; things not in possession, but due and recoverable from others (*choses* in action), might be recovered by the husband. A *chose* in action not reduced into actual possession, when the marriage was dissolved by death, reverted to the wife if she was the survivor; if the husband survived he could obtain possession by taking out letters of administration. A *chose* in action was to be distinguished from a specific thing which, although the property of the wife, was for the time being in the hands of another. In the latter case the property was in the wife, and passed at once to the husband; in the former the wife had a mere *jus in personam*, which the husband might enforce if he chose, but which was still capable of reverting to the wife if the husband died without enforcing it.

The *chattels real* of the wife (*i.e.*, personal property, dependent on, and partaking of, the nature of realty, such as leaseholds) passed to the husband, subject to the wife's right of survivorship, unless barred by the husband by some act done during his life. A disposition by will did not bar the wife's interest; but any disposition *inter vivos* by the husband was valid and effective.

The courts of equity, however, greatly modified the rules of the common law by the introduction of the wife's *separate estate*, *i.e.* property settled to the wife for her separate use, independently of her husband. The principle seems to have been originally admitted in a case of actual separation, when a fund was given for the maintenance of the wife while living apart from her husband. And the conditions under which separate estate might be enjoyed had taken the Court of Chancery many generations to develop. No particular form of words was necessary to create a separate estate, and the intervention of trustees, though common, was not necessary. A clear intention to deprive the husband of his common law rights was sufficient to do so. In such a case a married woman was entitled to deal with her property as if she was unmarried, although the earlier decisions were in favour of requiring her binding engagements to be in writing or under seal. But it was afterwards held that any engagements, clearly made with reference to the separate estate, would bind that estate, exactly as if the woman had been a *feme sole*. Connected with the doctrine of separate use was the equitable contrivance of *restraint on anticipation* with which later legislation has not interfered, whereby property might be so settled to the separate use of a married woman that she could not, during coverture, alienate it or anticipate the income. No such restraint is recognized in the case of a man or of a *feme sole*, and it depends entirely on the separate estate; and the separate estate has its existence only during coverture, so that a woman to whom such an estate is given may dispose of it so long as she is unmarried, but becomes bound by the restraint as soon as she is married. In yet another way the court of Chancery interfered to protect the interests of married women. When a

[1] Curtesy or courtesy has been explained by legal writers as "arising *by favour* of the law of England." The word has nothing to do with courtesy in the sense of complaisance.

husband sought the aid of that court to get possession of his wife's *choses* in action, he was required to make a provision for her and her children out of the fund sought to be recovered. This is called the wife's *equity to a settlement*, and is said to be based on the original maxim of Chancery jurisprudence, that "he who seeks equity must do equity." Two other property interests of minor importance are recognised. The wife's *pin-money* is a provision for the purchase of clothes and ornaments suitable to her husband's station, but it is not an absolute gift to the separate use of the wife; and a wife surviving her husband cannot claim for more than one year's arrears of pin-money. *Paraphernalia* are jewels and other ornaments given to the wife by her husband for the purpose of being worn by her, but not as her separate property. The husband may dispose of them by act *inter vivos* but not by will, unless the will confers other benefits on the wife, in which case she must elect between the will and the paraphernalia. She may also on the death of the husband claim paraphernalia, provided all creditors have been satisfied, her right being superior to that of any legatee.

The corresponding interest of the wife in the property of the husband is much more meagre and illusory. Besides a general right to maintenance at her husband's expense, she has at common law a right to *dower* (*q.v.*) in her husband's lands, and to a *pars rationabilis* (third) of his personal estate, if he dies intestate. The former, which originally was a solid provision for widows, has by the ingenuity of conveyancers, as well as by positive enactment, been reduced to very slender dimensions. It may be destroyed by a mere declaration to that effect on the part of the husband, as well as by his conveyance of the land or by his will.

The common practice of regulating the rights of husband, wife and children by marriage settlements obviates the hardships of the common law—at least for the women of the wealthier classes. The legislature by the Married Women's Property Acts of 1870, 1874, 1882 (which repealed and consolidated the acts of 1870 and 1874), 1893 and 1907 introduced very considerable changes. The chief provisions of the Married Women's Property Act 1882, which enormously improved the position of women unprotected by marriage settlement, are, shortly, that a married woman is capable of acquiring, holding and disposing of by will or otherwise, any real and personal property, in the same manner as if she were a *feme sole*, without the intervention of any trustee. The property of a woman married after the beginning of the act, whether belonging to her at the time of marriage or acquired after marriage, is held by her as a *feme sole*. The same is the case with property acquired after the beginning of the act by a woman married before the act. After marriage a woman remains liable for antenuptial debts and liabilities, and as between her and her husband, in the absence of contract to the contrary, her separate property is deemed primarily liable. The husband is only liable to the extent of property acquired from or through his wife. The act also contained provisions as to stock, investment, insurance, evidence and other matters. The effect of the act was to render obsolete the law as to what created a separate use or a reduction into possession of *choses* in action, as to equity to a settlement, as to fraud on the husband's marital rights, and as to the inability of one of two married persons to give a gift to the other. Also, in the case of a gift to a husband and wife in terms which would make them joint tenants if unmarried, they no longer take as one person but as two. The act contained a special saving of existing and future settlements; a settlement being still necessary where it is desired to secure only the enjoyment of the income to the wife and to provide for children. The act by itself would enable the wife, without regard to family claims, instantly to part with the whole of any property which might come to her. Restraint on anticipation was preserved by the act, subject to the liability of such property for antenuptial debts, and to the power given by the Conveyancing Act 1881 to bind a married woman's interest notwithstanding a clause of restraint. The Married Women's Property Act of 1893 repealed two clauses in the act of 1882, the exact bearing of which had been a matter of controversy. It provided specifically that every contract thereinafter entered into by a married woman, otherwise than as an agent, should be deemed to be a contract entered into by her with respect to and be binding upon her separate property, whether she was or was not in fact possessed of or entitled to any separate property at the time when she entered into such contract, that it should bind all separate property which she might at any time or thereafter be possessed of or entitled to, and that it should be enforceable by process of law against all property which she might thereafter, while discovert, be possessed of or entitled to. The act of 1907 enabled a married woman, without her husband, to dispose of or join in disposing of, real or personal property held by her solely or jointly as trustee or personal representative, in like manner as if she were a *feme sole*. It also provided that a settlement or agreement for settlement whether before or after marriage, respecting the property of the woman, should not be valid unless executed by her if she was of full age or confirmed by her after she attained full age. The Married Women's Property Act 1908 removed a curious anomaly by enacting that a married woman having separate property should be equally liable with single women and widows for the maintenance of parents who are in receipt of poor relief.

The British colonies generally have adopted the principles of the English acts of 1882 and 1893.

Law of Scotland.—The law of Scotland differs less from English law than the use of a very different terminology would lead us to suppose. The phrase *communio bonorum* has been employed to express the interest which the spouses have in the *movable* property of both, but its use has been severely censured as essentially inaccurate and misleading. It has been contended that there was no real community of goods, and no partnership or societas between the spouses. The wife's movable property, with certain exceptions, and subject to special agreements, became as absolutely the property of the husband as it did in English law. The notion of a *communio* was, however, favoured by the peculiar rights of the wife and children on the dissolution of the marriage. Previous to the Intestate Movable Succession (Scotland) Act 1855 the law stood as follows. The fund formed by the movable property of both spouses may be dealt with by the husband as he pleases during life; it is increased by his acquisitions and diminished by his debts. The respective shares contributed by husband and wife return on the dissolution of the marriage to them or their representatives if the marriage be dissolved within a year and a day, and without a living child. Otherwise the division is into two or three shares, according as children are existing or not at the dissolution of the marriage. On the death of the husband, his children take one-third (called *legitim*), the widow takes one-third (*jus relictae*), and the remaining one-third (the *dead part*) goes according to his will or to his next of kin. If there be no children, the *jus relictae* and the dead's part are each one-half. If the wife die before the husband, her representatives, whether children or not, are creditors for the value of her share. The statute abovementioned, however, enacts that "where a wife shall predecease her husband, the next of kin, executors or other representatives of such wife, whether testate or intestate, shall have no right to any share of the goods in communion; nor shall any legacy or bequest or testamentary disposition thereof by such wife, affect or attach to the said goods or any portion thereof." It also abolishes the rule by which the shares revert if the marriage does not subsist for a year and a day. Several later acts apply to Scotland some of the principles of the English Married Women's Property Acts. These are the Married Women's Property (Scotland) Act 1877, which protects the earnings, &c., of wives, and limits the husband's liability for antenuptial debts of the wife, the Married Women's Policies of Assurance (Scotland) Act 1880, which enables a woman to contract for a policy of assurance for her separate use, and the Married Women's Property (Scotland) Act 1881, which abolished the *jus mariti*.

A wife's *heritable* property does not pass to the husband on marriage, but he acquires a right to the administration and profits. His courtesy, as in English law, is also recognized. On the other hand, a widow has a *terce* or life-rent of a third part of the husband's heritable estate, unless she has accepted a conventional provision.

Continental Europe.—Since 1882 English legislation in the matter of married women's property has progressed from perhaps the most backward to the foremost place in Europe. By a curious contrast, the only two European countries where, in the absence of a settlement to the contrary, independence of the wife's property was recognized, were Russia and Italy. But there is now a marked tendency towards contractual emancipation. Sweden adopted a law on this subject in 1874, Denmark in 1880, Norway in 1888. Germany followed, the Civil Code which came into operation in 1900 (Art. 1367) providing that the wife's wages or earnings shall form part of her *Vorbehaltsgut* or separate property, which a previous article

(1365) placed beyond the husband's control. As regards property accruing to the wife in Germany by succession, will or gift *inter vivos*, it is only separate property where the donor has deliberately stipulated exclusion of the husband's right.

In France it seemed as if the system of community of property was ingrained in the institutions of the country. But a law of 1907 has brought France into line with other countries. This law gives a married woman sole control over earnings from her personal work and savings therefrom. She can with such money acquire personalty or realty, over the former of which she has absolute control. But if she abuses her rights by squandering her money or administering her property badly or imprudently the husband may apply to the court to have her freedom restricted.

American Law.—In the United States, the revolt against the common law theory of husband and wife was carried farther than in England, and legislation early tended in the direction of absolute equality between the sexes. Each state has, however, taken its own way and selected its own time for introducing modifications of the existing law, so that the legislation on this subject is now exceedingly complicated and difficult. James Schouler (*Law of Domestic Relations*) gives an account of the general result in the different states to which reference may be made. The peculiar system of Homestead Laws in many of the states (see HOMESTEAD and EXEMPTION LAWS) constitutes an inalienable provision for the wife and family of the householder.

HUSHI (Rumanian *Huşi*), the capital of the department of Falciu, Rumania; on a branch of the Jassy-Galatz railway, 9 m. W. of the river Pruth and the Russian frontier. Pop. (1900) 15,404, about one-fourth being Jews. Hushi is an episcopal see. The cathedral was built in 1491 by Stephen the Great of Moldavia. There are no important manufactures, but a large fair is held annually in September for the sale of live-stock, and wine is produced in considerable quantities. Hushi is said to have been founded in the 15th century by a colony of Hussites, from whom its name is derived. The treaty of the Pruth between Russia and Turkey was signed here in 1711.

HUSKISSON, WILLIAM (1770–1830), English statesman and financier, was descended from an old Staffordshire family of moderate fortune, and was born at Birch Moreton, Worcestershire, on the 11th of March 1770. Having been placed in his fourteenth year under the charge of his maternal great-uncle Dr Gem, physician to the English embassy at Paris, in 1783 he passed his early years amidst a political fermentation which led him to take a deep interest in politics. Though he approved of the French Revolution, his sympathies were with the more moderate party, and he became a member of the "club of 1789," instituted to support the new form of constitutional monarchy in opposition to the anarchical attempts of the Jacobins. He early displayed his mastery of the principles of finance by a *Discours* delivered in August 1790 before this society, in regard to the issue of assignats by the government. The *Discours* gained him considerable reputation, but as it failed in its purpose he withdrew from the society. In January 1793 he was appointed by Dundas to an office created to direct the execution of the Aliens Act; and in the discharge of his delicate duties he manifested such ability that in 1795 he was appointed under-secretary at war. In the following year he entered parliament as member for Morpeth, but for a considerable period he took scarcely any part in the debates. In 1800 he inherited a fortune from Dr Gem. On the retirement of Pitt in 1801 he resigned office, and after contesting Dover unsuccessfully he withdrew for a time into private life. Having in 1804 been chosen to represent Liskeard, he was on the restoration of the Pitt ministry appointed secretary of the treasury, holding office till the dissolution of the ministry after the death of Pitt in January 1806. After being elected for Harwich in 1807, he accepted the same office under the duke of Portland, but he withdrew from the ministry along with Canning in 1809. In the following year he published a pamphlet on the currency system, which confirmed his reputation as the ablest financier of his time; but his free-trade principles did not accord with those of his party. In 1812 he was returned for Chichester. When in 1814 he re-entered the public service, it was only as chief commissioner of woods and forests, but his influence was from this time very great in the commercial and financial legislation of the country. He took a prominent part in the corn-law debates of 1814 and 1815; and in 1819 he presented a memorandum to Lord Liverpool advocating a large reduction in the unfunded debt, and explaining a method for the resumption of cash payments, which was embodied in the act passed the same year. In 1821 he was a member of the committee appointed to inquire into the causes of the agricultural distress then prevailing, and the proposed relaxation of the corn laws embodied in the report was understood to have been chiefly due to his strenuous advocacy. In 1823 he was appointed president of the board of trade and treasurer of the navy, and shortly afterwards he received a seat in the cabinet. In the same year he was returned for Liverpool as successor to Canning, and as the only man who could reconcile the Tory merchants to a free trade policy. Among the more important legislative changes with which he was principally connected were a reform of the Navigation Acts, admitting other nations to a full equality and reciprocity of shipping duties; the repeal of the labour laws; the introduction of a new sinking fund; the reduction of the duties on manufactures and on the importation of foreign goods, and the repeal of the quarantine duties. In accordance with his suggestion Canning in 1827 introduced a measure on the corn laws proposing the adoption of a sliding scale to regulate the amount of duty. A misapprehension between Huskisson and the duke of Wellington led to the duke proposing an amendment, the success of which caused the abandonment of the measure by the government. After the death of Canning in the same year Huskisson accepted the secretaryship of the colonies under Lord Goderich, an office which he continued to hold in the new cabinet formed by the duke of Wellington in the following year. After succeeding with great difficulty in inducing the cabinet to agree to a compromise on the corn laws, Huskisson finally resigned office in May 1829 on account of a difference with his colleagues in regard to the disfranchisement of East Retford. On the 15th of September of the following year he was accidentally killed by a locomotive engine while present at the opening of the Liverpool and Manchester railway.

See the *Life of Huskisson*, by J. Wright (London, 1831).

HUSS (or HUS), **JOHN** (*c.* 1373–1415), Bohemian reformer and martyr, was born at Hussinecz,[1] a market village at the foot of the Böhmerwald, and not far from the Bavarian frontier, between 1373 and 1375, the exact date being uncertain. His parents appear to have been well-to-do Czechs of the peasant class. Of his early life nothing is recorded except that, notwithstanding the early loss of his father, he obtained a good elementary education, first at Hussinecz, and afterwards at the neighbouring town of Prachaticz. At, or only a very little beyond, the usual age he entered the recently (1348) founded university of Prague, where he became bachelor of arts in 1393, bachelor of theology in 1394, and master of arts in 1396. In 1398 he was chosen by the Bohemian "nation" of the university to an examinership for the bachelor's degree; in the same year he began to lecture also, and there is reason to believe that the philosophical writings of Wycliffe, with which he had been for some years acquainted, were his text-books. In October 1401 he was made dean of the philosophical faculty, and for the half-yearly period from October 1402 to April 1403 he held the office of rector of the university. In 1402 also he was made rector or curate (*capellarius*) of the Bethlehem chapel, which had in 1391 been erected and endowed by some zealous citizens of Prague for the purpose of providing good popular preaching in the Bohemian tongue. This appoinment had a deep influence on the already vigorous religious life of Huss himself; and one of the effects of the earnest and independent study of Scripture into which it led him was a profound conviction of the great value not only of the philosophical but also of the theological writings of Wycliffe.

This newly-formed sympathy with the English reformer did not, in the first instance at least, involve Huss in any conscious opposition to the established doctrines of Catholicism, or in any direct conflict with the authorities of the church; and for

[1] From which the name Huss, or more properly Hus, an abbreviation adopted by himself about 1396, is derived. Prior to that date he was invariably known as Johann Hussynecz, Hussinecz, Hussenicz or de Hussynecz.

several years he continued to act in full accord with his archbishop (Sbynjek, or Sbynko, of Hasenburg). Thus in 1405 he, with other two masters, was commissioned to examine into certain reputed miracles at Wilsnack, near Wittenberg, which had caused that church to be made a resort of pilgrims from all parts of Europe. The result of their report was that all pilgrimage thither from the province of Bohemia was prohibited by the archbishop on pain of excommunication, while Huss, with the full sanction of his superior, gave to the world his first published writing, entitled *De Omni Sanguine Christi Glorificato*, in which he declaimed in no measured terms against forged miracles and ecclesiastical greed, urging Christians at the same time to desist from looking for sensible signs of Christ's presence, but rather to seek Him in His enduring word. More than once also Huss, together with his friend Stanislaus of Znaim, was appointed to be synod preacher, and in this capacity he delivered at the provincial councils of Bohemia many faithful admonitions. As early as the 28th of May 1403, it is true, there had been held a university disputation about the new doctrines of Wycliffe, which had resulted in the condemnation of certain propositions presumed to be his; five years later (May 20, 1408) this decision had been refined into a declaration that these, forty-five in number, were not to be taught in any heretical, erroneous or offensive sense. But it was only slowly that the growing sympathy of Huss with Wycliffe unfavourably affected his relations with his colleagues in the priesthood. In 1408, however, the clergy of the city and archiepiscopal diocese of Prague laid before the archbishop a formal complaint against Huss, arising out of strong expressions with regard to clerical abuses of which he had made use in his public discourses; and the result was that, having been first deprived of his appointment as synodal preacher, he was, after a vain attempt to defend himself in writing, publicly forbidden the exercise of any priestly function throughout the diocese. Simultaneously with these proceedings in Bohemia, negotiations had been going on for the removal of the long-continued papal schism, and it had become apparent that a satisfactory solution could only be secured if, as seemed not impossible, the supporters of the rival popes, Benedict XIII. and Gregory XII., could be induced, in view of the approaching council of Pisa, to pledge themselves to a strict neutrality. With this end King Wenceslaus of Bohemia had requested the co-operation of the archbishop and his clergy, and also the support of the university, in both instances unsuccessfully, although in the case of the latter the Bohemian "nation," with Huss at its head, had only been overborne by the votes of the Bavarians, Saxons and Poles. There followed an expression of nationalist and particularistic as opposed to ultramontane and also to German feeling, which undoubtedly was of supreme importance for the whole of the subsequent career of Huss. In compliance with this feeling a royal edict (January 18, 1409) was issued, by which, in alleged conformity with Paris usage, and with the original charter of the university, the Bohemian "nation" received three votes, while only one was allotted to the other three "nations" combined; whereupon all the foreigners, to the number of several thousands, almost immediately withdrew from Prague, an occurrence which led to the formation shortly afterwards of the university of Leipzig.

It was a dangerous triumph for Huss; for his popularity at court and in the general community had been secured only at the price of clerical antipathy everywhere and of much German ill-will. Among the first results of the changed order of things were on the one hand the election of Huss (October 1409) to be again rector of the university, but on the other hand the appointment by the archbishop of an inquisitor to inquire into charges of heretical teaching and inflammatory preaching brought against him. He had spoken disrespectfully of the church, it was said, had even hinted that Antichrist might be found to be in Rome, had fomented in his preaching the quarrel between Bohemians and Germans, and had, notwithstanding all that had passed, continued to speak of Wycliffe as both a pious man and an orthodox teacher. The direct result of this investigation is not known, but it is impossible to disconnect from it the promulgation by Pope Alexander V., on the 20th of December 1409, of a bull which ordered the abjuration of all Wycliffite heresies and the surrender of all his books, while at the same time—a measure specially levelled at the pulpit of Bethlehem chapel—all preaching was prohibited except in localities which had been by long usage set apart for that use. This decree, as soon as it was published in Prague (March 9, 1410), led to much popular agitation, and provoked an appeal by Huss to the pope's better informed judgment; the archbishop, however, resolutely insisted on carrying out his instructions, and in the following July caused to be publicly burned, in the courtyard of his own palace, upwards of 200 volumes of the writings of Wycliffe, while he pronounced solemn sentence of excommunication against Huss and certain of his friends, who had in the meantime again protested and appealed to the new pope (John XXIII.). Again the populace rose on behalf of their hero, who, in his turn, strong in the conscientious conviction that "in the things which pertain to salvation God is to be obeyed rather than man," continued uninterruptedly to preach in the Bethlehem chapel, and in the university began publicly to defend the so-called heretical treatises of Wycliffe, while from king and queen, nobles and burghers, a petition was sent to Rome praying that the condemnation and prohibition in the bull of Alexander V. might be quashed. Negotiations were carried on for some months, but in vain; in March 1411 the ban was anew pronounced upon Huss as a disobedient son of the church, while the magistrates and councillors of Prague who had favoured him were threatened with a similar penalty in case of their giving him a contumacious support. Ultimately the whole city, which continued to harbour him, was laid under interdict; yet he went on preaching, and masses were celebrated as usual, so that at the date of Archbishop Sbynko's death in September 1411, it seemed as if the efforts of ecclesiastical authority had resulted in absolute failure.

The struggle, however, entered on a new phase with the appearance at Prague in May 1412 of the papal emissary charged with the proclamation of the papal bulls by which a religious war was decreed against the excommunicated King Ladislaus of Naples, and indulgence was promised to all who should take part in it, on terms similar to those which had been enjoyed by the earlier crusaders to the Holy Land. By his bold and thorough-going opposition to this mode of procedure against Ladislaus, and still more by his doctrine that indulgence could never be sold without simony, and could not be lawfully granted by the church except on condition of genuine contrition and repentance, Huss at last isolated himself, not only from the archiepiscopal party under Albik of Unitschow, but also from the theological faculty of the university, and especially from such men as Stanislaus of Znaim and Stephen Paletz, who until then had been his chief supporters. A popular demonstration, in which the papal bulls had been paraded through the streets with circumstances of peculiar ignominy and finally burnt, led to intervention by Wenceslaus on behalf of public order; three young men, for having openly asserted the unlawfulness of the papal indulgence after silence had been enjoined, were sentenced to death (June 1412); the excommunication against Huss was renewed, and the interdict again laid on all places which should give him shelter—a measure which now began to be more strictly regarded by the clergy, so that in the following December Huss had no alternative but to yield to the express wish of the king by temporarily withdrawing from Prague. A provincial synod, held at the instance of Wenceslaus in February 1413, broke up without having reached any practical result; and a commission appointed shortly afterwards also failed to bring about a reconciliation between Huss and his adversaries. The so-called heretic meanwhile spent his time partly at Kozihradek, some 45 m. south of Prague, and partly at Krakowitz in the immediate neighbourhood of the capital, occasionally giving a course of open-air preaching, but finding his chief employment in maintaining that copious correspondence of which some precious fragments still are extant, and in the composition of the treatise, *De Ecclesia*, which subsequently furnished most of the material for the capital charges brought against him, and was formerly considered the most important of his works, though it is mainly a transcript of Wycliffe's work of the same name.

During the year 1413 the arrangements for the meeting of a general council at Constance were agreed upon between Sigismund and Pope John XXIII. The objects originally contemplated had been the restoration of the unity of the church and its reform in head and members; but so great had become the prominence of Bohemian affairs that to these also a first place in the programme of the approaching oecumenical assembly required to be assigned, and for their satisfactory settlement the presence of Huss was necessary. His attendance was accordingly requested, and the invitation was willingly accepted as giving him a long-wished-for opportunity both of publicly vindicating himself from charges which he felt to be grievous, and of loyally making confession for Christ. He set out from Bohemia on the 14th of October 1414, not, however, until he had carefully ordered all his private affairs, with a presentiment, which he did not conceal, that in all probability he was going to his death. The journey, which appears to have been undertaken with the usual passport, and under the protection of several powerful Bohemian friends (John of Chlum, Wenceslaus of Duba, Henry of Chlum) who accompanied him, was a very prosperous one; and at almost all the halting-places he was received with a consideration and enthusiastic sympathy which he had hardly expected to meet with anywhere in Germany. On the 3rd of November he arrived at Constance; shortly afterwards there was put into his hands the famous imperial "safe conduct," the promise of which had been one of his inducements to quit the comparative security he had enjoyed in Bohemia. This safe conduct, which had been frequently printed, stated that Huss should, whatever judgment might be passed on him, be allowed to return freely to Bohemia. This by no means provided for his immunity from punishment. If faith to him had not been broken he would have been sent back to Bohemia to be punished by his sovereign, the king of Bohemia. The treachery of King Sigismund is undeniable, and was indeed admitted by the king himself. The safe conduct was probably indeed given by him to entice Huss to Constance. On the 4th of December the pope appointed a commission of three bishops to investigate the case against the heretic, and to procure witnesses; to the demand of Huss that he might be permitted to employ an agent in his defence a favourable answer was at first given, but afterwards even this concession to the forms of justice was denied. While the commission was engaged in the prosecution of its enquiries, the flight of Pope John XXIII. took place on the 20th of March, an event which furnished a pretext for the removal of Huss from the Dominican convent to a more secure and more severe place of confinement under the charge of the bishop of Constance at Gottlieben on the Rhine. On the 4th of May the temper of the council on the doctrinal questions in dispute was fully revealed in its unanimous condemnation of Wycliffe, especially of the so-called "forty-five articles" as erroneous, heretical, revolutionary. It was not, however, until the 5th of June that the case of Huss came up for hearing; the meeting, which was an exceptionally full one, took place in the refectory of the Franciscan cloister. Autograph copies of his work *De Ecclesia* and of the controversial tracts which he had written against Paletz and Stanislaus of Znaim having been acknowledged by him, the extracted propositions on which the prosecution based their charge of heresy were read; but as soon as the accused began to enter upon his defence, he was assailed by violent outcries, amidst which it was impossible for him to be heard, so that he was compelled to bring his speech to an abrupt close, which he did with the calm remark: "In such a council as this I had expected to find more propriety, piety and order." It was found necessary to adjourn the sitting until the 7th of June, on which occasion the outward decencies were better observed, partly no doubt from the circumstance that Sigismund was present in person. The propositions which had been extracted from the *De Ecclesia* were again brought up, and the relations between Wycliffe and Huss were discussed, the object of the prosecution being to fasten upon the latter the charge of having entirely adopted the doctrinal system of the former, including especially a denial of the doctrine of transubstantiation. The accused repudiated the charge of having abandoned the Catholic doctrine, while expressing hearty admiration and respect for the memory of Wycliffe. Being next asked to make an unqualified submission to the council, he expressed himself as unable to do so, while stating his willingness to amend his teaching wherever it had been shown to be false. With this the proceedings of the day were brought to a close. On the 8th of June the propositions extracted from the *De Ecclesia* were again taken up with some fulness of detail; some of these he repudiated as incorrectly given, others he defended; but when asked to make a general recantation he steadfastly declined, on the ground that to do so would be a dishonest admission of previous guilt. Among the propositions he could heartily abjure was that relating to transubstantiation; among those he felt constrained unflinchingly to maintain was one which had given great offence, to the effect that Christ, not Peter, is the head of the church to whom ultimate appeal must be made. The council, however, showed itself inaccessible to all his arguments and explanations, and its final resolution, as announced by Pierre d'Ailly, was threefold: first, that Huss should humbly declare that he had erred in all the articles cited against him; secondly, that he should promise on oath neither to hold nor teach them in the future; thirdly, that he should publicly recant them. On his declining to make this submission he was removed from the bar. Sigismund himself gave it as his opinion that it had been clearly proved by many witnesses that the accused had taught many pernicious heresies, and that even should he recant he ought never to be allowed to preach or teach again or to return to Bohemia, but that should he refuse recantation there was no remedy but the stake. During the next four weeks no effort was spared to shake the determination of Huss; but he steadfastly refused to swerve from the path which conscience had once made clear. "I write this," says he, in a letter to his friends at Prague, "in prison and in chains, expecting to-morrow to receive sentence of death, full of hope in God that I shall not swerve from the truth, nor abjure errors imputed to me by false witnesses." The sentence he expected was pronounced on the 6th of July in the presence of Sigismund and a full sitting of the council; once and again he attempted to remonstrate, but in vain, and finally he betook himself to silent prayer. After he had undergone the ceremony of degradation with all the childish formalities usual on such occasions, his soul was formally consigned by all those present to the devil, while he himself with clasped hands and uplifted eyes reverently committed it to Christ. He was then handed over to the secular arm, and immediately led to the place of execution, the council meanwhile proceeding unconcernedly with the rest of its business for the day. Many incidents recorded in the histories make manifest the meekness, fortitude and even cheerfulness with which he went to his death. After he had been tied to the stake and the faggots had been piled, he was for the last time urged to recant, but his only reply was: "God is my witness that I have never taught or preached that which false witnesses have testified against me. He knows that the great object of all my preaching and writing was to convert men from sin. In the truth of that gospel which hitherto I have written, taught and preached, I now joyfully die." The fire was then kindled, and his voice as it audibly prayed in the words of the "Kyrie Eleison" was soon stifled in the smoke. When the flames had done their office, the ashes that were left and even the soil on which they lay were carefully removed and thrown into the Rhine.

Not many words are needed to convey a tolerably adequate estimate of the character and work of the "pale thin man in mean attire," who in sickness and poverty thus completed the forty-sixth year of a busy life at the stake. The value of Huss as a scholar was formerly underrated. The publication of his *Super IV. Sententiarum* has proved that he was a man of profound learning. Yet his principal glory will always be founded on his spiritual teaching. It might not be easy to formulate precisely the doctrines for which he died, and certainly some of them, as, for example, that regarding the church, were such as many Protestants even would regard as unguarded and difficult to harmonize with the maintenance of external church order; but his is undoubtedly the honour of having been the chief intermediary in handing on from Wycliffe to Luther the torch which kindled the Reformation, and of having been one of the bravest of the martyrs who have died in the cause of honesty and freedom, of progress and of growth towards the light. (J. S. Bl.)

The works of Huss are usually classed under four heads: the dogmatical and polemical, the homiletical, the exegetical and the epistolary. In the earlier editions of his works sufficient care was not taken to distinguish between his own writings and those of Wycliffe and others who were associated with him. In connexion with his sermons it is worthy of note that by means of them and by his public teaching generally Huss exercised a considerable influence not only on the religious life of his time, but on the literary development of his native tongue. The earliest collected edition of his works, *Historia et monumenta Joannis Hus et Hieronymi Pragensis*, was published at Nuremberg in 1558 and was reprinted with a considerable quantity of new matter at Frankfort in 1715. A Bohemian edition of the works has been edited by K. J. Erben (Prague, 1865–1868), and the *Documenta J. Hus vitam, doctrinam, causam in Constantiensi concilio* (1869), edited by F. Palacky, is very valuable. More recently *Joannis Hus. Opera omnia* have been edited by W. Flojšhaus (Prague, 1904 fol.). The *De Ecclesia* was published by Ulrich von Hutten in 1520; other controversial writings by Otto Brumfels in 1524; and Luther wrote an interesting preface to *Epistolae Quaedam*, which were published in 1537. These *Epistolae* have been translated into French by E. de Bonnechose (1846), and the letters written during his imprisonment have been edited by C. von Kügelgen (Leipzig, 1902).

The best and most easily accessible information for the English reader on Huss is found in J. A. W. Neander's *Allgemeine Geschichte der christlichen Religion und Kirche*, translated by J. Torrey (1850–1858); in G. von Lechler's *Wiclif und die Vorgeschichte der Reformation*, translated by P. Lorimer (1878); in H. H. Milman's *History of Latin Christianity*, vol. viii. (1867); and in M. Creighton's *History of the Papacy* (1897). Among the earlier authorities is the *Historia Bohemica* of Aeneas Sylvius (1475). The *Acta* of the council of Constance (published by P. Labbe in his *Concilia*, vol. xvi., 1731; by H. von der Haardt in his *Magnum Constantiense concilium*, vol. vi., 1700; and by H. Finke in his *Acta concilii Constantiensis*, 1896); and J. Lenfant's *Histoire de la guerre des Hussites* (1731) and the same writer's *Histoire du concile de Constance* (1714) should be consulted. F. Palacky's *Geschichte Böhmens* (1864–1867) is also very useful. Monographs on Huss are very numerous. Among them may be mentioned J. A. von Helfert, *Studien über Hus und Hieronymus* (1853; this work is ultramontane in its sympathies); C. von Höfler, *Hus und der Abzug der deutschen Professoren und Studenten aus Prag* (1864); W. Berger, *Johannes Hus und König Sigmund* (1871); E. Denis, *Huss et la guerre des Hussites* (1878); P. Uhlmann, *König Sigmunds Geleit für Hus* (1894); J. Loserth, *Hus und Wiclif* (1884), translated into English by M. J. Evans (1884); A. Jeep, *Gerson, Wiclefus, Hussus, inter se comparati* (1857); and G. von Lechler, *Johannes Hus* (1889). See also Count Lützow, *The Life and Times of John Hus* (London, 1909).

HUSSAR, originally the name of a soldier belonging to a corps of light horse raised by Matthias Corvinus, king of Hungary, in 1458, to fight against the Turks. The Magyar *huszar*, from which the word is derived, was formerly connected with the Magyar *husz*, twenty, and was explained by a supposed raising of the troops by the taking of each twentieth man. According to the *New English Dictionary* the word is an adaptation of the Italian *corsaro*, corsair, a robber, and is found in 15th-century documents coupled with *praedones*. The hussar was the typical Hungarian cavalry soldier, and, in the absence of good light cavalry in the regular armies of central and western Europe, the name and character of the hussars gradually spread into Prussia, France, &c. Frederick the Great sent Major H. J. von Zieten to study the work of this type of cavalry in the Austrian service, and Zieten so far improved on the Austrian model that he defeated his old teacher, General Baranyai, in an encounter between the Prussian and Austrian hussars at Rothschloss in 1741. The typical uniform of the Hungarian hussar was followed with modifications in other European armies. It consisted of a busby or a high cylindrical cloth cap, jacket with heavy braiding, and a dolman or pelisse, a loose coat worn hanging from the left shoulder. The hussar regiments of the British army were converted from light dragoons at the following dates: 7th (1805), 10th and 15th (1806), 18th (1807, and again on revival after disbandment, 1858), 8th (1822), 11th (1840), 20th (late 2nd Bengal European Cavalry) (1860), 13th, 14th, and 19th (late 1st Bengal European Cavalry) (1861). The 21st Lancers were hussars from 1862 to 1897.

HUSSITES, the name given to the followers of John Huss (1369–1415), the Bohemian reformer. They were at first often called Wycliffites, as the theological theories of Huss were largely founded on the teachings of Wycliffe. Huss indeed laid more stress on church reform than on theological controversy. On such matters he always writes as a disciple of Wycliffe. The Hussite movement may be said to have sprung from three sources, which are however closely connected. Bohemia, which had first received Christianity from the East, was from geographical and other causes long but very loosely connected with the Church of Rome. The connexion became closer at the time when the schism with its violent controversies between the rival pontiffs, waged with the coarse invective customary to medieval theologians, had brought great discredit on the papacy. The terrible rapacity of its representatives in Bohemia, which increased in proportion as it became more difficult to obtain money from western countries such as England and France, caused general indignation; and this was still further intensified by the gross immorality of the Roman priests. The Hussite movement was also a democratic one, an uprising of the peasantry against the landowners at a period when a third of the soil belonged to the clergy. Finally national enthusiasm for the Slavic race contributed largely to its importance. The towns, in most cases creations of the rulers of Bohemia who had called in German immigrants, were, with the exception of the "new town" of Prague, mainly German; and in consequence of the regulations of the university, Germans also held almost all the more important ecclesiastical offices—a condition of things greatly resented by the natives of Bohemia, which at this period had reached a high degree of intellectual development.

The Hussite movement assumed a revolutionary character as soon as the news of the death of Huss reached Prague. The knights and nobles of Bohemia and Moravia, who were in favour of church reform, sent to the council at Constance (September 2nd, 1415) a protest, known as the "*protestatio Bohemorum*" which condemned the execution of Huss in the strongest language. The attitude of Sigismund, king of the Romans, who sent threatening letters to Bohemia declaring that he would shortly "drown all Wycliffites and Hussites," greatly incensed the people. Troubles broke out in various parts of Bohemia, and many Romanist priests were driven from their parishes. Almost from the first the Hussites were divided into two sections, though many minor divisions also arose among them. Shortly before his death Huss had accepted a doctrine preached during his absence by his adherents at Prague, namely that of "utraquism," *i.e.* the obligation of the faithful to receive communion in both kinds (*sub utraque specie*). This doctrine became the watchword of the moderate Hussites who were known as the Utraquists or Calixtines (*calix*, the chalice), in Bohemian, *podoboji*; while the more advanced Hussites were soon known as the Taborites, from the city of Tabor that became their centre.

Under the influence of his brother Sigismund, king of the Romans, King Wenceslaus endeavoured to stem the Hussite movement. A certain number of Hussites lead by Nicolas of Hus—no relation of John Huss—left Prague. They held meetings in various parts of Bohemia, particularly at Usti, near the spot where the town of Tabor was founded soon afterwards. At these meetings Sigismund was violently denounced, and the people everywhere prepared for war. In spite of the departure of many prominent Hussites the troubles at Prague continued. On the 30th of July 1419, when a Hussite procession headed by the priest John of Želivo (in Ger. Selau) marched through the streets of Prague, stones were thrown at the Hussites from the windows of the town-hall of the "new town." The people, headed by John Žižka (1376–1424), threw the burgomaster and several town-councillors, who were the instigators of this outrage, from the windows and they were immediately killed by the crowd. On hearing this news King Wenceslaus was seized with an apoplectic fit, and died a few days afterwards. The death of the king resulted in renewed troubles in Prague and in almost all parts of Bohemia. Many Romanists, mostly Germans—for they had almost all remained faithful to the papal cause—were expelled from the Bohemian cities. In Prague, in November 1419, severe fighting took place between the Hussites and the mercenaries whom Queen Sophia (widow of Wenceslaus and regent after the death of her husband) had hurriedly collected. After a considerable part of the city had been destroyed a truce was concluded on the 13th of November. The nobles, who though favourable to the Hussite cause yet supported the regent, promised to act as mediators with Sigismund; while the citizens of Prague consented to restore to the royal forces the castle of Vyšehrad, which had fallen into their hands. Žižka, who disapproved of this compromise, left Prague and retired to Plzeň (Pilsen). Unable to maintain himself there he marched to southern Bohemia, and after defeating the Romanists at Sudoměř—the first pitched battle of the Hussite wars—he arrived at Usti, one of the earliest meeting-places of the Hussites. Not considering its situation sufficiently strong, he moved to the neighbouring new settlement of the Hussites, to which the biblical name of Tabor was given. Tabor soon became the centre of the advanced Hussites, who differed from the Utraquists by recognizing only two sacraments—Baptism and Communion—and by rejecting most of the ceremonial of the Roman Church. The ecclesiastical organization of Tabor had a somewhat puritanic character, and the government was established on a thoroughly democratic basis. Four captains of the people (*hejtmane*) were elected, one of whom was Žižka; and a very strictly military discipline was instituted.

Sigismund, king of the Romans, had, by the death of his brother Wenceslaus without issue, acquired a claim on the Bohemian crown; though it was then, and remained till much later, doubtful whether Bohemia was an hereditary or an elective monarchy. A firm adherent of the Church of Rome, Sigismund was successful in obtaining aid from the pope. Martin V. issued a bull on the 17th of March 1420 which proclaimed a crusade " for the destruction of the Wycliffites, Hussites and all other heretics in Bohemia." The vast army of crusaders, with which were Sigismund and many German princes, and which consisted of adventurers attracted by the hope of pillage from all parts of Europe, arrived before Prague on the 30th of June and immediately began the siege of the city, which had, however, soon to be abandoned (see Žižka, John). Negotiations took place for a settlement of the religious differences. The united Hussites formulated their demands in a statement known as the " articles of Prague." This document, the most important of the Hussite period, runs thus in the wording of the contemporary chronicler, Laurence of Brezova:—

I. The word of God shall be preached and made known in the kingdom of Bohemia freely and in an orderly manner by the priests of the Lord. . . .

II. The sacrament of the most Holy Eucharist shall be freely administered in the two kinds, that is bread and wine, to all the faithful in Christ who are not precluded by mortal sin—according to the word and disposition of Our Saviour.

III. The secular power over riches and worldly goods which the clergy possesses in contradiction to Christ's precept, to the prejudice of its office and to the detriment of the secular arm, shall be taken and withdrawn from it, and the clergy itself shall be brought back to the evangelical rule and an apostolic life such as that which Christ and his apostles led. . . .

IV. All mortal sins, and in particular all public and other disorders, which are contrary to God's law, shall in every rank of life be duly and judiciously prohibited and destroyed by those whose office it is.

These articles, which contain the essence of the Hussite doctrine, were rejected by Sigismund, mainly through the influence of the papal legates, who considered them prejudicial to the authority of the Roman see. Hostilities therefore continued. Though Sigismund had retired from Prague, the castles of Vyšehrad and Hradčany remained in possession of his troops. The citizens of Prague laid siege to the Vyšehrad, and towards the end of October (1420) the garrison was on the point of capitulating through famine. Sigismund attempted to relieve the fortress, but was decisively defeated by the Hussites on the 1st of November near the village of Pankrác. The castles of Vyšehrad and Hradčany now capitulated, and shortly afterwards almost all Bohemia fell into the hands of the Hussites. Internal troubles prevented them from availing themselves completely of their victory. At Prague a demagogue, the priest John of Želivo, for a time obtained almost unlimited authority over the lower classes of the townsmen; and at Tabor a communistic movement (that of the so-called Adamites) was sternly suppressed by Žižka. Shortly afterwards a new crusade against the Hussites was undertaken. A large German army entered Bohemia, and in August 1421 laid siege to the town of Zatec (Saaz). The crusaders hoped to be joined in Bohemia by King Sigismund, but that prince was detained in Hungary. After an unsuccessful attempt to storm Zatec the crusaders retreated somewhat ingloriously, on hearing that the Hussite troops were approaching. Sigismund only arrived in Bohemia at the end of the year 1421. He took possession of the town of Kutna Hora (Kuttenberg), but was decisively defeated by Žižka at Německy Brod (Deutschbrod) on the 6th of January 1422. Bohemia was now again for a time free from foreign intervention, but internal discord again broke out caused partly by theological strife, partly by the ambition of agitators. John of Želivo was on the 9th of March 1422 arrested by the town council of Prague and decapitated. There were troubles at Tabor also, where a more advanced party opposed Žižka's authority. Bohemia obtained a temporary respite when, in 1422, Prince Sigismund Korybutovič of Poland became for a short time ruler of the country. His authority was recognized by the Utraquist nobles, the citizens of Prague, and the more moderate Taborites, including Žižka. Korybutovič, however, remained but a short time in Bohemia; after his departure civil war broke out, the Taborites opposing in arms the more moderate Utraquists, who at this period are also called by the chroniclers the " Praguers," as Prague was their principal stronghold. On the 27th of April 1423, Žižka now again leading, the Taborites defeated at Horic the Utraquist army under Čenek of Wartemberg; shortly afterwards an armistice was concluded at Konopišt.

Papal influence had meanwhile succeeded in calling forth a new crusade against Bohemia, but it resulted in complete failure. In spite of the endeavours of their rulers, the Slavs of Poland and Lithuania did not wish to attack the kindred Bohemians; the Germans were prevented by internal discord from taking joint action against the Hussites; and the king of Denmark, who had landed in Germany with a large force intending to take part in the crusade, soon returned to his own country. Free for a time from foreign aggression, the Hussites invaded Moravia, where a large part of the population favoured their creed; but, again paralysed by dissensions, soon returned to Bohemia. The city of Königgrätz (Králové Hradec), which had been under Utraquist rule, espoused the doctrine of Tabor, and called Žižka to its aid. After several military successes gained by Žižka (*q.v.*) in 1423 and the following year, a treaty of peace between the Hussites was concluded on the 13th of September 1424 at Liben, a village near Prague, now part of that city.

In 1426 the Hussites were again attacked by foreign enemies. In June of that year their forces, led by Prokop the Great—who took the command of the Taborites shortly after Žižka's death in October 1424—and Sigismund Korybutovič, who had returned to Bohemia, signally defeated the Germans at Aussig (Usti nad Labem). After this great victory, and another at Tachau in 1427, the Hussites repeatedly invaded Germany, though they made no attempt to occupy permanently any part of the country.

The almost uninterrupted series of victories of the Hussites now rendered vain all hope of subduing them by force of arms. Moreover, the conspicuously democratic character of the Hussite movement caused the German princes, who were afraid that such views might extend to their own countries, to desire peace. Many Hussites, particularly the Utraquist clergy, were also in favour of peace. Negotiations for this purpose were to take place at the oecumenical council which had been summoned to meet at Basel on the 3rd of March 1431. The Roman see reluctantly consented to the presence of heretics at this council, but indignantly rejected the suggestion of the Hussites that members of the Greek Church, and representatives of all Christian creeds, should also be present. Before definitely giving its consent to peace negotiations, the Roman Church determined on making a last effort to reduce the Hussites to subjection. On the 1st of August 1431 a large army of crusaders, under Frederick, margrave of Brandenburg, whom Cardinal Cesarini accompanied as papal legate, crossed the Bohemian frontier; on the 14th of August it reached the town of Domažlice (Tauss); but on the arrival of the Hussite army under Prokop the crusaders immediately took to flight, almost without offering resistance.

On the 15th of October the members of the council, who had already assembled at Basel, issued a formal invitation to the Hussites to take part in its deliberations. Prolonged negotiations ensued; but finally a Hussite embassy, led by Prokop and including John of Rokycan, the Taborite bishop Nicolas of Pelhřimov, the "English Hussite," Peter Payne and many others, arrived at Basel on the 4th of January 1433. It was found impossible to arrive at an agreement. Negotiations were not, however, broken off; and a change in the political situation of Bohemia finally resulted in a settlement. In 1434 war again broke out between the Utraquists and the Taborites. On the 30th of May of that year the Taborite army, led by Prokop the Great and Prokop the Less, who both fell in the battle, was totally defeated and almost annihilated at Lipan. The moderate party thus obtained the upper hand; and it formulated its demands in a document which was finally accepted by the Church of Rome in a slightly modified form, and which is known as "the compacts." The compacts, mainly founded on the articles of Prague, declare that:—

1. The Holy Sacrament is to be given freely in both kinds to all Christians in Bohemia and Moravia, and to those elsewhere who adhere to the faith of these two countries.
2. All mortal sins shall be punished and extirpated by those whose office it is so to do.
3. The word of God is to be freely and truthfully preached by the priests of the Lord, and by worthy deacons.
4. The priests in the time of the law of grace shall claim no ownership of worldly possessions.

On the 5th of July 1436 the compacts were formally accepted and signed at Iglau, in Moravia, by King Sigismund, by the Hussite delegates, and by the representatives of the Roman Church. The last-named, however, refused to recognize as archbishop of Prague, John of Rokycan, who had been elected to that dignity by the estates of Bohemia. The Utraquist creed, frequently varying in its details, continued to be that of the established church of Bohemia till all non-Roman religious services were prohibited shortly after the battle of the White Mountain in 1620. The Taborite party never recovered from its defeat at Lipan, and after the town of Tabor had been captured by George of Poděbrad in 1452 Utraquist religious worship was established there. The Bohemian brethren, whose intellectual originator was Peter Chelčicky, but whose actual founders were Brother Gregory, a nephew of Archbishop Rokycan, and Michael, curate of Zamberk, to a certain extent continued the Taborite traditions, and in the 15th and 16th centuries included most of the strongest opponents of Rome in Bohemia. J. A. Komensky (Comenius), a member of the brotherhood, claimed for the members of his church that they were the genuine inheritors of the doctrines of Hus. After the beginning of the German Reformation many Utraquists adopted to a large extent the doctrines of Luther and Calvin; and in 1567 obtained the repeal of the compacts, which no longer seemed sufficiently far-reaching. From the end of the 16th century the inheritors of the Hussite tradition in Bohemia were included in the more general name of "Protestants" borne by the adherents of the Reformation.

All histories of Bohemia devote a large amount of space to the Hussite movement. See Count Lützow, *Bohemia; an Historical Sketch* (London, 1896); Palacky, *Geschichte von Böhmen*; Bachmann, *Geschichte Böhmens*; L. Krummel, *Geschichte der böhmischen Reformation* (Gotha, 1866) and *Utraquisten und Taboriten* (Gotha, 1871); Ernest Denis, *Huss et la guerre des Hussites* (Paris, 1878); H. Toman, *Husitské Válečnictví* (Prague, 1898). (L.)

HUSTING (O. Eng. *hústing*, from Old Norwegian *hústhing*), the "thing" or "ting," *i.e.* assembly, of the household of personal followers or retainers of a king, earl or chief, contrasted with the "folkmoot," the assembly of the whole people. "Thing" meant an inanimate object, the ordinary meaning at the present day, also a cause or suit, and an assembly; a similar development of meaning is found in the Latin *res*. The word still appears in the names of the legislative assemblies of Norway, the *Storthing* and of Iceland, the *Althing*. "Husting," or more usually in the plural "hustings," was the name of a court of the city of London. This court was formerly the county court for the city and was held before the lord mayor, the sheriffs and aldermen, for pleas of land, common pleas and appeals from the sheriffs. It had probate jurisdiction and wills were registered. All this jurisdiction has long been obsolete, but the court still sits occasionally for registering gifts made to the city. The charter of Canute (1032) contains a reference to "hustings" weights, which points to the early establishment of the court. It is doubtful whether courts of this name were held in other towns, but John Cowell (1554–1611) in his *Interpreter* (1601) *s.v.*, "Hustings," says that according to Fleta there were such courts at Winchester, York, Lincoln, Sheppey and elsewhere, but the passage from Fleta, as the *New English Dictionary* points out, does not necessarily imply this (II. lv. *Habet etiam Rex curiam in civitatibus . . . et in locis . . . sicut in Hustingis London, Winton, &c.*). The ordinary use of "hustings" at the present day for the platform from which a candidate speaks at a parliamentary or other election, or more widely for a political candidate's election campaign, is derived from the application of the word, first to the platform in the Guildhall on which the London court was held, and next to that from which the public nomination of candidates for a parliamentary election was formerly made, and from which the candidate addressed the electors. The Ballot Act of 1872 did away with this public declaration of the nomination.

HUSUM, a town in the Prussian province of Schleswig-Holstein, in a fertile district $2\frac{1}{2}$ m. inland from the North Sea, on the canalized Husumer Au, which forms its harbour and roadstead, 99 m. N.W. from Hamburg on a branch line from Tönning. Pop. (1900) 8268. It has steam communication with the North Frisian Islands (Nordstrand, Föhr and Sylt), and is a port for the cattle trade with England. Besides a ducal palace and park, it possesses an Evangelical church and a gymnasium. Cattle markets are held weekly, and in them, as also in cereals, a lively export trade is done. There are also extensive oyster fisheries, the property of the state, the yield during the season being very considerable. Husum is the birthplace of Johann Georg Forchhammer (1794–1865), the mineralogist, Peter Wilhelm Forchhammer (1801–1894), the archaeologist, and Theodore Storm (1817–1888), the poet, to the last of whom a monument has been erected here.

Husum is first mentioned in 1252, and its first church was built in 1431. Wisby rights were granted it in 1582, and in 1603 it received municipal privileges from the duke of Holstein. It suffered greatly from inundations in 1634 and 1717.

See Christiansen, *Die Geschichte Husums* (Husum, 1903); and Henningsen, *Das Stiftungsbuch der Stadt Husum* (Husum, 1904).

HUTCHESON, FRANCIS (1694–1746), English philosopher, was born on the 8th of August 1694. His birthplace was probably the townland of Drumalig, in the parish of Saintfield and county of Down, Ireland.[1] Though the family had sprung from Ayrshire, in Scotland, both his father and grandfather were ministers of dissenting congregations in the north of Ireland. Hutcheson was educated partly by his grandfather, partly at an academy, where according to his biographer, Dr Leechman, he was taught

[1] See *Belfast Magazine* for August 1813.

"the ordinary scholastic philosophy which was in vogue in those days." In 1710 he entered the university of Glasgow, where he spent six years, at first in the study of philosophy, classics and general literature, and afterwards in the study of theology. On quitting the university, he returned to the north of Ireland, and received a licence to preach. When, however, he was about to enter upon the pastorate of a small dissenting congregation he changed his plans on the advice of a friend and opened a private academy in Dublin. In Dublin his literary attainments gained him the friendship of many prominent inhabitants. Among these was Archbishop King (author of the *De origine mali*), who resisted all attempts to prosecute Hutcheson in the archbishop's court for keeping a school without the episcopal licence. Hutcheson's relations with the clergy of the Established Church, especially with the archbishops of Armagh and Dublin, Hugh Boulter (1672–1742) and William King (1650–1729), seem to have been most cordial, and his biographer, in speaking of "the inclination of his friends to serve him, the schemes proposed to him for obtaining promotion," &c., probably refers to some offers of preferment, on condition of his accepting episcopal ordination. These offers, however, were unavailing.

While residing in Dublin, Hutcheson published anonymously the four essays by which he is best known, namely, the *Inquiry concerning Beauty, Order, Harmony and Design*, the *Inquiry concerning Moral Good and Evil*, in 1725, the *Essay on the Nature and Conduct of the Passions and Affections* and *Illustrations upon the Moral Sense*, in 1728. The alterations and additions made in the second edition of these *Essays* were published in a separate form in 1726. To the period of his Dublin residence are also to be referred the *Thoughts on Laughter* (a criticism of Hobbes) and the *Observations on the Fable of the Bees*, being in all six letters contributed to *Hibernicus' Letters*, a periodical which appeared in Dublin (1725–1727, 2nd ed. 1734). At the end of the same period occurred the controversy in the *London Journal* with Gilbert Burnet (probably the second son of Dr Gilbert Burnet, bishop of Salisbury), on the "True Foundation of Virtue or Moral Goodness." All these letters were collected in one volume (Glasgow, 1772).

In 1729 Hutcheson succeeded his old master, Gershom Carmichael, in the chair of moral philosophy in the university of Glasgow. It is curious that up to this time all his essays and letters had been published anonymously, though their authorship appears to have been well known. In 1730 he entered on the duties of his office, delivering an inaugural lecture (afterwards published), *De naturali hominum socialitate*. It was a great relief to him after the drudgery of school work to secure leisure for his favourite studies; "non levi igitur laetitia commovebar cum almam matrem Academiam me, suum olim alumnum, in libertatem asseruisse audiveram." Yet the works on which Hutcheson's reputation rests had already been published.

The remainder of his life he devoted to his professorial duties. His reputation as a teacher attracted many young men, belonging to dissenting families, from England and Ireland, and he enjoyed a well-deserved popularity among both his pupils and his colleagues. Though somewhat quick-tempered, he was remarkable for his warm feelings and generous impulses. He was accused in 1738 before the Glasgow presbytery for "following two false and dangerous doctrines: first, that the standard of moral goodness was the promotion of the happiness of others; and second, that we could have a knowledge of good and evil without and prior to a knowledge of God" (Rae, *Life of Adam Smith*, 1895). The accusation seems to have had no result.

In addition to the works named, the following were published during Hutcheson's lifetime: a pamphlet entitled *Considerations on Patronage* (1735); *Philosophiae moralis institutio compendiaria, ethices et jurisprudentiae naturalis elementa continens, lib. iii.* (Glasgow, 1742); *Metaphysicae synopsis ontologiam et pneumatologiam complectens* (Glasgow, 1742). The last work was published anonymously. After his death, his son, Francis Hutcheson (*c.* 1722–1773), author of a number of popular songs (*e.g.* "As Colin one evening," "Jolly Bacchus," "Where Weeping Yews"), published much the longest, though by no means the most interesting, of his works, *A System of Moral Philosophy, in Three Books* (2 vols., London, 1755). To this is prefixed a life of the author, by Dr William Leechman (1706–1785), professor of divinity in the university of Glasgow. The only remaining work assigned to Hutcheson is a small treatise on *Logic* (Glasgow, 1764). This compendium, together with the *Compendium of Metaphysics*, was republished at Strassburg in 1722.

Thus Hutcheson dealt with metaphysics, logic and ethics. His importance is, however, due almost entirely to his ethical writings, and among these primarily to the four essays and the letters published during his residence in Dublin. His standpoint has a negative and a positive aspect; he is in strong opposition to Thomas Hobbes and Bernard de Mandeville, and in fundamental agreement with Shaftesbury (Anthony Ashley Cooper, 3rd earl of Shaftesbury), whose name he very properly coupled with his own on the title-page of the first two essays. There are no two names, perhaps, in the history of English moral philosophy, which stand in a closer connexion. The analogy drawn between beauty and virtue, the functions assigned to the moral sense, the position that the benevolent feelings form an original and irreducible part of our nature, and the unhesitating adoption of the principle that the test of virtuous action is its tendency to promote the general welfare are obvious and fundamental points of agreement between the two authors.

I. *Ethics.*—According to Hutcheson, man has a variety of senses, internal as well as external, reflex as well as direct, the general definition of a sense being "any determination of our minds to receive ideas independently on our will, and to have perceptions of pleasure and pain" (*Essay on the Nature and Conduct of the Passions*, sect. 1). He does not attempt to give an exhaustive enumeration of these "senses," but, in various parts of his works, he specifies, besides the five external senses commonly recognized (which, he rightly hints, might be added to),—(1) consciousness, by which each man has a perception of himself and of all that is going on in his own mind (*Metaph. Syn.* pars i. cap. 2); (2) the sense of beauty (sometimes called specifically "an internal sense"); (3) a public sense, or sensus communis, "a determination to be pleased with the happiness of others and to be uneasy at their misery"; (4) the moral sense, or "moral sense of beauty in actions and affections, by which we perceive virtue or vice, in ourselves or others"; (5) a sense of honour, or praise and blame, "which makes the approbation or gratitude of others the necessary occasion of pleasure, and their dislike, condemnation or resentment of injuries done by us the occasion of that uneasy sensation called shame"; (6) a sense of the ridiculous. It is plain, as the author confesses, that there may be "other perceptions, distinct from all these classes," and, in fact, there seems to be no limit to the number of "senses" in which a psychological division of this kind might result.

Of these "senses" that which plays the most important part in Hutcheson's ethical system is the "moral sense." It is this which pronounces immediately on the character of actions and affections, approving those which are virtuous, and disapproving those which are vicious. "His principal design," he says in the preface to the two first treatises, "is to show that human nature was not left quite indifferent in the affair of virtue, to form to itself observations concerning the advantage or disadvantage of actions, and accordingly to regulate its conduct. The weakness of our reason, and the avocations arising from the infirmity and necessities of our nature, are so great that very few men could ever have formed those long deductions of reasons which show some actions to be in the whole advantageous to the agent, and their contraries pernicious. The Author of nature has much better furnished us for a virtuous conduct than our moralists seem to imagine, by almost as quick and powerful instructions as we have for the preservation of our bodies. He has made virtue a lovely form, to excite our pursuit of it, and has given us strong affections to be the springs of each virtuous action." Passing over the appeal to final causes involved in this and similar passages, as well as the assumption that the "moral sense" has had no growth or history, but was "implanted" in man exactly in the condition in which it is now to be found among the more civilized races, an assumption common to the systems of both Hutcheson and Butler, it may be remarked that this use of the term "sense" has a tendency to obscure the real nature of the process which goes on in an act of moral judgment. For, as is so clearly established by Hume, this act really consists of two parts: one an act of deliberation, more or less prolonged, resulting in an intellectual judgment; the other a reflex feeling, probably instantaneous, of satisfaction at actions which we denominate good, of dissatisfaction at those which we denominate bad. By the intellectual part of this process we refer the action or habit to a certain class; but no sooner is the intellectual process completed than there is excited in us a feeling similar to that which myriads of actions and habits of the same class, or deemed to be of the same class, have excited in us on former occasions. Now, supposing the latter part of this process to be instantaneous, uniform and exempt from error, the former certainly is not. All mankind may, apart from their selfish interests, approve that which is virtuous or makes for the general good, but surely they entertain the most widely divergent opinions, and, in fact, frequently arrive at directly opposite conclusions as to particular actions and habits. This obvious distinction is undoubtedly recognized by Hutcheson in his analysis of the mental process preceding moral action, nor does he invariably ignore it, even when treating of the moral approbation or disapprobation which is subsequent on action. None the less, it remains true that Hutcheson, both by his phraseology, and by the language in which he describes the process of moral approbation, has done much to favour that loose, popular view of morality which, ignoring the necessity of deliberation and reflection, encourages hasty resolves and unpremeditated judgments. The term "moral sense" (which, it may be noticed, had already been employed by Shaftesbury, not only, as Dr Whewell appears to intimate, in the margin, but also in the text of his *Inquiry*), if invariably coupled with the term "moral judgment," would be open to little objection; but, taken alone, as designating the complex process of moral approbation, it is liable to lead not only to serious misapprehension but to grave practical errors. For, if each man's decisions are solely the result of an immediate intuition of the moral sense, why be at any pains to test, correct or review them? Or why educate a faculty whose decisions are infallible? And how do we account for differences in the moral decisions of different societies, and the observable changes in a man's own views? The expression has, in fact, the fault of most metaphorical terms: it leads to an exaggeration of the truth which it is intended to suggest.

But though Hutcheson usually describes the moral faculty as acting instinctively and immediately, he does not, like Butler, confound the moral faculty with the moral standard. The test or criterion of right action is with Hutcheson, as with Shaftesbury, its tendency to promote the general welfare of mankind. He thus anticipates the utilitarianism of Bentham—and not only in principle, but even in the use of the phrase "the greatest happiness for the greatest number" (*Inquiry concerning Moral Good and Evil*, sect. 3).

It is curious that Hutcheson did not realize the inconsistency of this external criterion with his fundamental ethical principle. Intuition has no possible connexion with an empirical calculation of results, and Hutcheson in adopting such a criterion practically denies his fundamental assumption.

As connected with Hutcheson's virtual adoption of the utilitarian standard may be noticed a kind of moral algebra, proposed for the purpose of "computing the morality of actions." This calculus occurs in the *Inquiry concerning Moral Good and Evil*, sect. 3.

The most distinctive of Hutcheson's ethical doctrines still remaining to be noticed is what has been called the "benevolent theory" of morals. Hobbes had maintained that all our actions, however disguised under apparent sympathy, have their roots in self-love. Hutcheson not only maintains that benevolence is the sole and direct source of many of our actions, but, by a not unnatural recoil, that it is the only source of those actions of which, on reflection, we approve. Consistently with this position, actions which flow from self-love only are pronounced to be morally indifferent. But surely, by the common consent of civilized men, prudence, temperance, cleanliness, industry, self-respect and, in general, the "personal virtues," are regarded, and rightly regarded, as fitting objects of moral approbation. This consideration could hardly escape any author, however wedded to his own system, and Hutcheson attempts to extricate himself from the difficulty by laying down the position that a man may justly regard himself as a part of the rational system, and may thus "be, in part, an object of his own benevolence" (*Ibid.*),—a curious abuse of terms, which really concedes the question at issue. Moreover, he acknowledges that, though self-love does not merit approbation, neither, except in its extreme forms, does it merit condemnation, indeed the satisfaction of the dictates of self-love is one of the very conditions of the preservation of society. To press home the inconsistencies involved in these various statements would be a superfluous task.

Benevolence.

The vexed question of liberty and necessity appears to be carefully avoided in Hutcheson's professedly ethical works. But, in the *Synopsis metaphysicae*, he touches on it in three places, briefly stating both sides of the question, but evidently inclining to that which he designates as the opinion of the Stoics in opposition to what he designates as the opinion of the Peripatetics. This is substantially the same as the doctrine propounded by Hobbes and Locke (to the latter of whom Hutcheson refers in a note), namely, that our will is determined by motives in conjunction with our general character and habit of mind, and that the only true liberty is the liberty of acting as we will, not the liberty of willing as we will. Though, however, his leaning is clear, he carefully avoids dogmatizing, and deprecates the angry controversies to which the speculations on this subject had given rise.

It is easy to trace the influence of Hutcheson's ethical theories on the systems of Hume and Adam Smith. The prominence given by these writers to the analysis of moral action and moral approbation, with the attempt to discriminate the respective provinces of the reason and the emotions in these processes, is undoubtedly due to the influence of Hutcheson. To a study of the writings of Shaftesbury and Hutcheson we might, probably, in large measure, attribute the unequivocal adoption of the utilitarian standard by Hume, and, if this be the case, the name of Hutcheson connects itself, through Hume, with the names of Priestley, Paley and Bentham. Butler's *Sermons* appeared in 1726, the year after the publication of Hutcheson's two first essays, and the parallelism between the "conscience" of the one writer and the "moral sense" of the other is, at least, worthy of remark.

II. *Mental Philosophy.*—In the sphere of mental philosophy and logic Hutcheson's contributions are by no means so important or original as in that of moral philosophy. They are interesting mainly as a link between Locke and the Scottish school. In the former subject the influence of Locke is apparent throughout. All the main outlines of Locke's philosophy seem, at first sight, to be accepted as a matter of course. Thus, in stating his theory of the moral sense, Hutcheson is peculiarly careful to repudiate the doctrine of innate ideas (see, for instance, *Inquiry concerning Moral Good and Evil*, sect. 1 *ad fin.*, and sect. 4; and compare *Synopsis Metaphysicae*, pars i. cap. 2). At the same time he shows more discrimination than does Locke in distinguishing between the two uses of this expression, and between the legitimate and illegitimate form of the doctrine (*Syn. Metaph.* pars i. cap. 2). All our ideas are, as by Locke, referred to external or internal sense, or, in other words, to sensation and reflection (see, for instance, *Syn. Metaph.* pars i. cap. 1; *Logicae Compend.* pars i. cap. 1; *System of Moral Philosophy*, bk. i. ch. 1). It is, however, a most important modification of Locke's doctrine, and one which connects Hutcheson's mental philosophy with that of Reid, when he states that the ideas of extension, figure, motion and rest "are more properly ideas accompanying the sensations of sight and touch than the sensations of either of these senses"; that the idea of self accompanies every thought, and that the ideas of number, duration and existence accompany every other idea whatsoever (see *Essay on the Nature and Conduct of the Passions*, sect. i. art. 1; *Syn. Metaph.* pars i. cap. 1, pars ii. cap. 1; Hamilton on *Reid*, p. 124, note). Other important points in which Hutcheson follows the lead of Locke are his depreciation of the importance of the so-called laws of thought, his distinction between the primary and secondary qualities of bodies, the position that we cannot know the inmost essences of things ("intimae rerum naturae sive essentiae"), though they excite various ideas in us, and the assumption that external things are known only through the medium of ideas (*Syn. Metaph.* pars i. cap. 1), though, at the same time, we are assured of the existence of an external world corresponding to these ideas. Hutcheson attempts to account for our assurance of the reality of an external world by referring it to a natural instinct (*Syn. Metaph.* pars i. cap. 1). Of the correspondence or similitude between our ideas of the primary qualities of things and the things themselves God alone can be assigned as the cause. This similitude has been effected by Him through a law of nature. "Haec prima qualitatum primariarum perceptio, sive mentis actio quaedam sive passio dicatur, non alia similitudinis aut convenientiae inter ejusmodi ideas et res ipsas causa assignari posse videtur, quam ipse Deus, qui certa naturae lege hoc efficit, ut notiones, quae rebus praesentibus excitantur, sint ipsis similes, aut saltem earum habitudines, si non veras quantitates, depingant" (pars ii. cap. 1). Locke does speak of God "annexing" certain ideas to certain motions of bodies; but nowhere does he propound a theory so definite as that here propounded by Hutcheson, which reminds us at least as much of the speculations of Malebranche as of those of Locke.

Amongst the more important points in which Hutcheson diverges from Locke is his account of the idea of personal identity, which he appears to have regarded as made known to us directly by consciousness. The distinction between body and mind, *corpus* or *materia* and *res cogitans*, is more emphatically accentuated by Hutcheson than by Locke. Generally, he speaks as if we had a direct consciousness of mind as distinct from body (see, for instance, *Syn. Metaph.* pars ii. cap. 3), though, in the posthumous work on *Moral Philosophy*, he expressly states that we know mind as we know body "by qualities immediately perceived though the substance of both be unknown" (bk. i. ch. 1). The distinction between perception proper and sensation proper, which occurs by implication though it is not explicitly worked out (see Hamilton's *Lectures on Metaphysics*, Lect. 24; Hamilton's edition of *Dugald Stewart's Works*, v. 420), the imperfection of the ordinary division of the external senses into five classes, the limitation of consciousness to a special mental faculty (severely criticized in Sir W. Hamilton's *Lectures on Metaphysics*, Lect. xii.) and the disposition to refer on disputed questions of philosophy not so much to formal arguments as to the testimony of consciousness and our natural instincts are also amongst the points in which Hutcheson supplemented or departed from the philosophy of Locke. The last point can hardly fail to suggest the "common-sense philosophy" of Reid.

Thus, in estimating Hutcheson's position, we find that in particular questions he stands nearer to Locke, but in the general spirit of his philosophy he seems to approach more closely to his Scottish successors.

The short *Compendium of Logic*, which is more original than such works usually are, is remarkable chiefly for the large proportion of psychological matter which it contains. In these parts of the book Hutcheson mainly follows Locke. The technicalities of the subject are passed lightly over, and the book is readable. It may be specially noticed that he distinguishes between the mental result and its verbal expression [idea—term; judgment—proposition], that he constantly employs the word "idea," and that he defines logical truth as "convenientia signorum cum rebus significatis" (or "propositionis convenientia cum rebus ipsis," *Syn. Metaph.* pars i. cap 3), thus implicitly repudiating a merely formal view of logic.

III. *Aesthetics.*—Hutcheson may further be regarded as one of the earliest modern writers on aesthetics. His speculations on this subject are contained in the *Inquiry concerning Beauty, Order, Harmony and Design*, the first of the two treatises published in 1725. He maintains that we are endowed with a special sense by which we perceive beauty, harmony and proportion. This is a *reflex* sense, because it presupposes the action of the external senses of sight and hearing. It may be called an internal sense, both in order to distinguish its perceptions from the mere perceptions of sight and hearing, and because "in some other affairs, where our external senses are not much concerned, we discern a sort of beauty, very like in many respects to that observed in sensible objects, and accompanied with like pleasure" (*Inquiry, &c.*, sect. 1). The latter reason leads him to call attention to the beauty perceived in universal truths, in the operations of general causes and in moral principles and actions. Thus, the analogy between beauty and virtue, which was so favourite a topic with Shaftesbury, is prominent in the writings of Hutcheson also. Scattered up and down the treatise there are many important and interesting observations which our limits prevent us from noticing. But to the student of mental philosophy it may be specially interesting to remark that Hutcheson both applies the principle of association to explain our ideas of beauty and also sets limits to its application, insisting on there being "a natural power of perception or sense of beauty in objects, antecedent to all custom, education or example" (see *Inquiry, &c.*, sects. 6, 7; Hamilton's *Lectures on Metaphysics*, Lect. 44 *ad fin.*).

Hutcheson's writings naturally gave rise to much controversy. To say nothing of minor opponents, such as "Philaretus" (Gilbert Burnet, already alluded to), Dr John Balguy (1686–1748), prebendary of Salisbury, the author of two tracts on "The Foundation of Moral Goodness," and Dr John Taylor (1694–1761) of Norwich, a minister of considerable reputation in his time (author of *An Examination of the Scheme of Morality advanced by Dr Hutcheson*), the essays appear to have suggested, by antagonism, at least two works which hold a permanent place in the literature of English ethics—Butler's *Dissertation on the Nature of Virtue*, and Richard Price's *Treatise of Moral Good and Evil* (1757). In this latter work the author maintains, in opposition to Hutcheson, that actions are *in themselves* right or wrong, that right and wrong are simple ideas incapable of analysis, and that these ideas are perceived immediately by the understanding. We thus see that, not only directly but also through the replies which it called forth, the system of Hutcheson, or at least the system of Hutcheson combined with that of Shaftesbury, contributed, in large measure, to the formation and development of some of the most important of the modern schools of ethics (see especially art. ETHICS).

AUTHORITIES.—Notices of Hutcheson occur in most histories, both of general philosophy and of moral philosophy, as, for instance, in pt. vii. of Adam Smith's *Theory of Moral Sentiments*; Mackintosh's *Progress of Ethical Philosophy*; Cousin, *Cours d'histoire de la philosophie morale du XVIII^e siècle*; Whewell's *Lectures on the History of Moral Philosophy in England*; A. Bain's *Mental and Moral Science*; Noah Porter's Appendix to the English translation of Ueberweg's *History of Philosophy*; Sir Leslie Stephen's *History of English Thought in the Eighteenth Century*, &c. See also Martineau, *Types of Ethical Theory* (London, 1902); W. R. Scott, *Francis Hutcheson* (Cambridge, 1900); Albee, *History of English Utilitarianism* (London, 1902); T. Fowler, *Shaftesbury and Hutcheson* (London, 1882); J. McCosh, *Scottish Philosophy* (New York, 1874). Of Dr Leechman's *Biography* of Hutcheson we have already spoken. J. Veitch gives an interesting account of his professorial work in Glasgow, *Mind*, ii. 209-212. (T. F.; X.)

HUTCHINSON, ANNE (*c.* 1600–1643), American religious enthusiast, leader of the "Antinomians" in New England, was born in Lincolnshire, England, about 1600. She was the daughter of a clergyman named Francis Marbury, and, according to tradition, was a cousin of John Dryden. She married William Hutchinson, and in 1634 emigrated to Boston, Massachusetts, as a follower and admirer of the Rev. John Cotton. Her orthodoxy was suspected and for a time she was not admitted to the church, but soon she organized meetings among the Boston women, among whom her exceptional ability and her services as a nurse had given her great influence; and at these meetings she discussed and commented upon recent sermons and gave expression to her own theological views. The meetings became increasingly popular, and were soon attended not only by the women but even by some of the ministers and magistrates, including Governor Henry Vane. At these meetings she asserted that she, Cotton and her brother-in-law, the Rev. John Wheelwright—whom she was trying to make second "teacher" in the Boston church—were under a "covenant of grace," that they had a special inspiration, a "peculiar indwelling of the Holy Ghost," whereas the Rev. John Wilson, the pastor of the Boston church, and the other ministers of the colony were under a "covenant of works." Anne Hutchinson was, in fact, voicing a protest against the legalism of the Massachusetts Puritans, and was also striking at the authority of the clergy in an intensely theocratic community. In such a community a theological controversy inevitably was carried into secular politics, and the entire colony was divided into factions. Mrs Hutchinson was supported by Governor Vane, Cotton, Wheelwright and the great majority of the Boston church; opposed to her were Deputy-Governor John Winthrop, Wilson and all of the country magistrates and churches. At a general fast, held late in January 1637, Wheelwright preached a sermon which was taken as a criticism of Wilson and his friends. The strength of the parties was tested at the General Court of Election of May 1637, when Winthrop defeated Vane for the governorship. Cotton recanted, Vane returned to England in disgust, Wheelwright was tried and banished and the rank and file either followed Cotton in making submission or suffered various minor punishments. Mrs Hutchinson was tried (November 1637) by the General Court chiefly for "traducing the ministers," and was sentenced to banishment; later, in March 1638, she was tried before the Boston church and was formally excommunicated. With William Coddington (d. 1678), John Clarke and others, she established a settlement on the island of Aquidneck (now Rhode Island) in 1638. Four years later, after the death of her husband, she settled on Long Island Sound near what is now New Rochelle, Westchester county, New York, and was killed in an Indian rising in August 1643, an event regarded in Massachusetts as a manifestation of Divine Providence. Anne Hutchinson and her followers were called "Antinomians," probably more as a term of reproach than with any special reference to her doctrinal theories; and the controversy in which she was involved is known as the "Antinomian Controversy."

See C. F. Adams, *Antinomianism in the Colony of Massachusetts Bay*, vol. xiv. of the Prince Society Publications (Boston, 1894); and *Three Episodes of Massachusetts History* (Boston and New York, 1896).

HUTCHINSON, JOHN (1615–1664), Puritan soldier, son of Sir Thomas Hutchinson of Owthorpe, Nottinghamshire, and of Margaret, daughter of Sir John Byron of Newstead, was baptized on the 18th of September 1615. He was educated at Nottingham and Lincoln schools and at Peterhouse, Cambridge, and in 1637 he entered Lincoln's Inn. On the outbreak of the great Rebellion he took the side of the Parliament, and was made in 1643 governor of Nottingham Castle, which he defended against external attacks and internal divisions, till the triumph of the parliamentary cause. He was chosen member for Nottinghamshire in March 1646, took the side of the Independents, opposed the offers of the king at Newport, and signed the death-warrant. Though a member at first of the council of state, he disapproved of the subsequent political conduct of Cromwell and took no further part in politics during the lifetime of the protector. He resumed his seat in the recalled Long Parliament in May 1659, and followed Monk in opposing Lambert, believing that the former intended to maintain the commonwealth. He was returned to the Convention Parliament for Nottingham but expelled on the 9th of June 1660, and while not excepted from the Act of Indemnity was declared incapable of holding public office. In October 1663, however, he was arrested upon suspicion of being concerned in the Yorkshire plot, and after a rigorous confinement in the Tower of London, of which he published an account (reprinted in the Harleian *Miscellany*, vol. iii.), and in Sandown Castle, Kent, he died on the 11th of September 1664. His career draws its chief interest from the *Life* by his wife, Lucy, daughter of Sir Allen Apsley, written after the death of her husband but not published till 1806 (since often reprinted), a work not only valuable for the picture which it gives of the man and of the time in which he lived, but for the simple beauty of its style, and the naïveté with which the writer records her sentiments and opinions, and details the incidents of her private life.

See the edition of Lucy Hutchinson's *Memoirs of the Life of Colonel Hutchinson* by C. H. Firth (1885); Brit. Mus. *Add. MSS.* 25,901 (a fragment of the *Life*), also *Add. MSS.* 19, 333, 36,247 f. 51; *Notes and Queries*, 7, ser. iii. 25, viii. 422; *Monk's Contemporaries*, by Guizot.

HUTCHINSON, JOHN (1674–1737), English theological writer, was born at Spennithorne, Yorkshire, in 1674. He served as steward in several families of position, latterly in that of the duke of Somerset, who ultimately obtained for him the post of riding purveyor to the master of the horse, a sinecure worth about £200 a year. In 1700 he became acquainted with Dr John Woodward (1665–1728) physician to the duke and author of a work entitled *The Natural History of the Earth*, to whom he entrusted a large number of fossils of his own collecting, along with a mass of manuscript notes, for arrangement and publication. A misunderstanding as to the manner in which these should be dealt with was the immediate occasion of the publication by Hutchinson in 1724 of *Moses's Principia*, part i., in which Woodward's *Natural History* was bitterly ridiculed, his conduct with regard to the mineralogical specimens not obscurely characterized, and a refutation of the Newtonian doctrine of gravitation seriously attempted. It was followed by part ii. in 1727, and by various other works, including *Moses's Sine Principio*, 1730; *The Confusion of Tongues and Trinity of the Gentiles*, 1731; *Power Essential and Mechanical, or what power belongs to God and what to his creatures, in which the design of Sir I. Newton and Dr Samuel Clarke is laid open*, 1732; *Glory or Gravity*, 1733; *The Religion of Satan, or Antichrist Delineated*, 1736. He taught that the Bible contained the elements not only of true religion but also of all rational philosophy. He held that the Hebrew must be read without points, and his interpretation rested largely on fanciful symbolism. Bishop George Horne of Norwich was during some of his earlier years an avowed Hutchinsonian; and William Jones of Nayland continued to be so to the end of his life.

A complete edition of his publications, edited by Robert Spearman and Julius Bate, appeared in 1748 (12 vols.); an *Abstract* of these followed in 1753; and a *Supplement*, with *Life* by Spearman prefixed, in 1765.

HUTCHINSON, SIR JONATHAN (1828–), English surgeon and pathologist, was born on the 23rd of July 1828 at Selby, Yorkshire, his parents belonging to the Society of Friends. He entered St Bartholomew's Hospital, became a member of the Royal College of Surgeons in 1850 (F.R.C.S. 1862), and rapidly gained reputation as a skilful operator and a scientific inquirer. He was president of the Hunterian Society in 1869 and 1870, professor of surgery and pathology at the College of Surgeons from 1877 to 1882, president of the Pathological Society, 1879–1880, of the Ophthalmological Society, 1883, of the Neurological Society, 1887, of the Medical Society, 1890, and of the Royal Medical and Chirurgical in 1894–1896. In 1889 he was president of the Royal College of Surgeons. He was a member of two Royal Commissions, that of 1881 to inquire into the provision for smallpox and fever cases in the London hospitals, and that of 1889–1896 on vaccination and leprosy. He also acted as honorary secretary to the Sydenham Society. His activity in the cause of scientific surgery and in advancing the study of the natural sciences was unwearying. His lectures on neuro-pathogenesis, gout, leprosy, diseases of the tongue, &c., were full of original observation; but his principal work was connected with the study of syphilis, on which he became the first living authority. He was the founder of the London Polyclinic or Postgraduate School of Medicine; and both in his native town of Selby and at Haslemere, Surrey, he started (about 1890) educational museums for popular instruction in natural history. He published several volumes on his own subjects, was editor of the quarterly *Archives of Surgery*, and was given the Hon. LL.D. degree by both Glasgow and Cambridge. After his retirement from active consultative work he continued to take great interest in the question of leprosy, asserting the existence of a definite connexion between this disease and the eating of salted fish. He received a knighthood in 1908.

HUTCHINSON, THOMAS (1711–1780), the last royal governor of the province of Massachusetts, son of a wealthy merchant of Boston, Mass., was born there on the 9th of September 1711. He graduated at Harvard in 1727, then became an apprentice in his father's counting-room, and for several years devoted himself to business. In 1737 he began his public career as a member of the Boston Board of Selectmen, and a few weeks later he was elected to the General Court of Massachusetts Bay, of which he was a member until 1740 and again from 1742 to 1749, serving as speaker in 1747, 1748 and 1749. He consistently contended for a sound financial system, and vigorously opposed the operations of the "Land Bank" and the issue of pernicious bills of credit. In 1748 he carried through the General Court a bill providing for the cancellation and redemption of the outstanding paper currency. Hutchinson went to England in 1740 as the representative of Massachusetts in a boundary dispute with New Hampshire. He was a member of the Massachusetts Council from 1749 to 1756, was appointed judge of probate in 1752 and was chief justice of the superior court of the province from 1761 to 1769, was lieutenant-governor from 1758 to 1771, acting as governor in the latter two years, and from 1771 to 1774 was governor. In 1754 he was a delegate from Massachusetts to the Albany Convention, and, with Franklin, was a member of the committee appointed to draw up a plan of union. Though he recognized the legality of the Stamp Act of 1765, he considered the measure inexpedient and impolitic and urged its repeal, but his attitude was misunderstood; he was considered by many to have instigated the passage of the Act, and in August 1765 a mob sacked his Boston residence and destroyed many valuable manuscripts and documents. He was acting governor at the time of the "Boston Massacre" in 1770, and was virtually forced by the citizens of Boston, under the leadership of Samuel Adams, to order the removal of the British troops from the town. Throughout the pre-Revolutionary disturbances in Massachusetts he was the representative of the British ministry, and though he disapproved of some of the ministerial measures he felt impelled to enforce them and necessarily incurred the hostility of the Whig or Patriot element. In 1774, upon the appointment of General Thomas Gage as military governor he went to England, and acted as an adviser to George III. and the British ministry on American affairs, uniformly counselling moderation. He died at Brompton, now part of London, on the 3rd of June 1780.

He wrote *A Brief Statement of the Claim of the Colonies* (1764); a *Collection of Original Papers relative to the History of Massachusetts Bay* (1769), reprinted as *The Hutchinson Papers* by the Prince Society in 1865; and a judicious, accurate and very valuable *History of the Province of Massachusetts Bay* (vol. i., 1764, vol. ii., 1767, and vol. iii., 1828). His *Diary and Letters, with an Account of his Administration*, was published at Boston in 1884–1886.

See James K. Hosmer's *Life of Thomas Hutchinson* (Boston, 1896), and a biographical chapter in John Fiske's *Essays Historical and Literary* (New York, 1902). For an estimate of Hutchinson as an historian, see M. C. Tyler's *Literary History of the American Revolution* (New York, 1897).

HUTCHINSON, a city and the county-seat of Reno county, Kansas, U.S.A., in the broad bottom-land on the N. side of the Arkansas river. Pop. (1900) 9379, of whom 414 were foreign-born and 442 negroes; (1910 census) 16,364. It is served by the Atchison, Topeka & Santa Fé, the Missouri Pacific and the Chicago, Rock Island & Pacific railways. The principal public buildings are the Federal building and the county court house. The city has a public library, and an industrial reformatory is maintained here by the state. Hutchinson is situated in a stock-raising, fruit-growing and farming region (the principal products of which are wheat, Indian corn and fodder), with which it has a considerable wholesale trade. An enormous deposit of rock salt underlies the city and its vicinity, and Hutchinson's principal industry is the manufacture (by the open-pan and grainer processes) and the shipping of salt; the city has one of the largest salt plants in the world. Among the other manufactures are flour, creamery products, soda-ash, straw-board, planing-mill products and packed meats. Natural gas is largely used as a factory fuel. The city's factory product was valued at $2,031,048 in 1905, an increase of 31·8% since 1900. Hutchinson was chartered as a city in 1871.

HUTTEN, PHILIPP VON (*c.* 1511–1546), German knight, was a relative of Ulrich von Hutten and passed some of his early years at the court of the emperor Charles V. Later he joined the band of adventurers which under Georg Hohermuth, or George of Spires, sailed to Venezuela, or Venosala as Hutten calls it, with the object of conquering and exploiting this land in the interests of the Augsburg family of Welser. The party landed at Coro in February 1535 and Hutten accompanied Hohermuth on his long and toilsome expedition into the interior in search of treasure. After the death of Hohermuth in December 1540 he became captain-general of Venezuela. Soon after this event he vanished into the interior, returning after five years of wandering to find that a Spaniard, Juan de Caravazil, or Caravajil, had been appointed governor in his absence. With his travelling companion, Bartholomew Welser the younger, he was seized by Caravazil in April 1546 and the two were afterwards put to death.

Hutten left some letters, and also a narrative of the earlier part of his adventures, this *Zeitung aus India Junkher Philipps von Hutten* being published in 1785.

HUTTEN, ULRICH VON (1488–1523), was born on the 21st of April 1488, at the castle of Steckelberg, near Fulda, in Hesse. Like Erasmus or Pirckheimer, he was one of those men who form the bridge between Humanists and Reformers. He lived with both, sympathized with both, though he died before the Reformation had time fully to develop. His life may be divided into four parts:—his youth and cloister-life (1488–1504); his wanderings in pursuit of knowledge (1504–1515); his strife with Ulrich of Württemberg (1515–1519); and his connexion with the Reformation (1519–1523). Each of these periods had its own special antagonism, which coloured Hutten's career: in the first, his horror of dull monastic routine; in the second, the ill-treatment he met with at Greifswald; in the third, the crime of Duke Ulrich; in the fourth, his disgust with Rome and with Erasmus. He was the eldest son of a poor and not undistinguished knightly family. As he was mean of stature and sickly his father destined him for the cloister, and he was sent to the Benedictine house at Fulda; the thirst for learning there seized on him, and in 1505 he fled from the monastic life, and won his freedom with the sacrifice of his worldly prospects, and at the cost of incurring his father's undying anger. From the Fulda cloister he went first to Cologne, next to Erfurt, and then to Frankfort-on-Oder on the opening in 1506 of the new university of that town. For a time he was in Leipzig, and in 1508 we find him a shipwrecked beggar on the Pomeranian coast. In 1509 the university of Greifswald welcomed him, but here too those who at first received him kindly became his foes; the sensitive ill-regulated youth, who took the liberties of genius, wearied his burgher patrons; they could not brook the poet's airs and vanity, and ill-timed assertions of his higher rank. Wherefore he left Greifswald, and as he went was robbed of clothes and books, his only baggage, by the servants of his late friends; in the dead of winter, half starved, frozen, penniless, he reached Rostock. Here again the Humanists received him gladly, and under their protection he wrote against his Greifswald patrons, thus beginning the long list of his satires and fierce attacks on personal or public foes. Rostock could not hold him long; he wandered on to Wittenberg and Leipzig, and thence to Vienna, where he hoped to win the emperor Maximilian's favour by an elaborate national poem on the war with Venice. But neither Maximilian nor the university of Vienna would lift a hand for him, and he passed into Italy, where, at Pavia, he sojourned throughout 1511 and part of 1512. In the latter year his studies were interrupted by war; in the siege of Pavia by papal troops and Swiss, he was plundered by both sides, and escaped, sick and penniless, to Bologna; on his recovery he even took service as a private soldier in the emperor's army.

This dark period lasted no long time; in 1514 he was again in Germany, where, thanks to his poetic gifts and the friendship of Eitelwolf von Stein (d. 1515), he won the favour of the elector of Mainz, Archbishop Albert of Brandenburg. Here high dreams of a learned career rose on him; Mainz should be made the metropolis of a grand Humanist movement, the centre of good style and literary form. But the murder in 1515 of his relative Hans von Hutten by Ulrich, duke of Württemberg, changed the whole course of his life; satire, chief refuge of the weak, became Hutten's weapon; with one hand he took his part in the famous *Epistolae obscurorum virorum*, and with the other launched scathing letters, eloquent Ciceronian orations, or biting satires against the duke. Though the emperor was too lazy and indifferent to smite a great prince, he took Hutten under his protection and bestowed on him the honour of a laureate crown in 1517. Hutten, who had meanwhile revisited Italy, again attached himself to the electoral court at Mainz; and he was there when in 1518 his friend Pirckheimer wrote, urging him to abandon the court and dedicate himself to letters. We have the poet's long reply, in an epistle on his "way of life," an amusing mixture of earnestness and vanity, self-satisfaction and satire; he tells his friend that his career is just begun, that he has had twelve years of wandering, and will now enjoy himself a while in patriotic literary work; that he has by no means deserted the humaner studies, but carries with him a little library of standard books. Pirckheimer in his burgher life may have ease and even luxury; he, a knight of the empire, how can he condescend to obscurity? He must abide where he can shine.

In 1519 he issued in one volume his attacks on Duke Ulrich, and then, drawing sword, took part in the private war which overthrew that prince; in this affair he became intimate with Franz von Sickingen, the champion of the knightly order (Ritterstand). Hutten now warmly and openly espoused the Lutheran cause, but he was at the same time mixed up in the attempt of the "Ritterstand" to assert itself as the militia of the empire against the independence of the German princes. Soon after this time he discovered at Fulda a copy of the manifesto of the emperor Henry IV. against Hildebrand, and published it with comments as an attack on the papal claims over Germany. He hoped thereby to interest the new emperor Charles V., and the higher orders in the empire, in behalf of German liberties; but the appeal failed. What Luther had achieved by speaking to cities and common folk in homely phrase, because he touched heart and conscience, that the far finer weapons of Hutten failed to effect, because he tried to touch the more cultivated sympathies and dormant patriotism of princes and bishops, nobles and knights. And so he at once gained an undying name in the republic of letters and ruined his own career. He showed that the artificial verse-making of the Humanists could be connected with the new outburst of genuine German poetry. The Minnesinger was gone; the new national singer, a Luther or a Hans Sachs, was heralded by the stirring lines of Hutten's pen. These have in them a splendid natural swing and ring, strong and patriotic, though unfortunately addressed to knight and landsknecht rather than to the German people.

The poet's high dream of a knightly national regeneration had a rude awakening. The attack on the papacy, and Luther's vast and sudden popularity, frightened Elector Albert, who dismissed Hutten from his court. Hoping for imperial favour, he betook himself to Charles V.; but that young prince would have none of him. So he returned to his friends, and they rejoiced greatly to see him still alive; for Pope Leo X. had ordered him to be arrested and sent to Rome, and assassins dogged his steps. He now attached himself more closely to Franz von Sickingen and the knightly movement. This also came to a disastrous end in the capture of the Ebernberg, and Sickingen's death; the higher nobles had triumphed; the archbishops avenged themselves on Lutheranism as interpreted by the knightly order. With Sickingen Hutten also finally fell. He fled to Basel, where Erasmus refused to see him, both for fear of his loathsome diseases, and also because the beggared knight was sure to borrow money from him. A paper war consequently broke out between the two Humanists, which embittered Hutten's last days, and stained the memory of Erasmus. From Basel Ulrich dragged himself to Mülhausen; and when the vengeance of Erasmus drove him thence, he went to Zurich. There the large heart of Zwingli welcomed him; he helped him with money, and found him a quiet refuge with the pastor of the little isle of Ufnau on the Zurich lake. There the frail and worn-out poet, writing swift satire to the end, died at the end of August or beginning of September 1523 at the age of thirty-five. He left behind him some debts due to compassionate friends; he did not even own a single book, and all his goods amounted to the clothes on his back, a bundle of letters, and that valiant pen which had fought so many a sharp battle, and had won for the poor knight-errant a sure place in the annals of literature.

Ulrich von Hutten is one of those men of genius at whom propriety is shocked, and whom the mean-spirited avoid. Yet through his short and buffeted life he was befriended, with wonderful charity and patience, by the chief leaders of the Humanist movement. For, in spite of his irritable vanity, his immoral life and habits, his odious diseases, his painful restlessness, Hutten had much in him that strong men could love. He passionately loved the truth, and was ever open to all good influences. He was a patriot, whose soul soared to ideal schemes and a grand utopian restoration of his country. In spite of all, his was a frank and noble nature; his faults chiefly the faults of genius ill-controlled, and of a life cast in the eventful changes of an age of novelty. A swarm of writings issued from his pen; at first the smooth elegance of his Latin prose and verse seemed strangely to miss his real character; he was the Cicero and Ovid of Germany before he became its Lucian.

His chief works were his *Ars versificandi* (1511); the *Nemo* (1518); a work on the *Morbus Gallicus* (1519); the volume of Steckelberg complaints against Duke Ulrich (including his four *Ciceronian Orations*, his *Letters* and the *Phalarismus*) also in 1519; the *Vadismus* (1520); and the controversy with Erasmus at the end of his life. Besides these were many admirable poems in Latin and German. It is not known with certainty how far Hutten was the parent of the celebrated *Epistolae obscurorum virorum*, that famous satire on monastic ignorance as represented by the theologians of Cologne with which the friends of Reuchlin defended him. At first the cloister-world, not discerning its irony, welcomed the work as a defence of their position; though their eyes were soon opened by the favour with which the learned world received it. The *Epistolae* were eagerly bought up; the first part (41 letters) appeared at the end of 1515; early in 1516 there was a second edition; later in 1516 a third, with an appendix of seven letters; in 1517 appeared the second part (62 letters), to which a fresh appendix of eight letters was subjoined soon after. In 1909 the Latin text of the *Epistolae* with an English translation was published by F. G. Stokes. Hutten, in a letter addressed to Robert Crocus, denied that he was the author of the book, but there is no doubt as to his connexion with it. Erasmus was of opinion that there were three authors, of whom Crotus Rubianus was the originator of the idea, and Hutten a chief contributor. D. F. Strauss, who dedicates to the subject a chapter of his admirable work on Hutten, concludes that he had no share in the first part, but that his hand is clearly visible in the second part, which he attributes in the main to him. To him is due the more serious and severe tone of that bitter portion of the satire. See W. Brecht, *Die Verfasser der Epistolae obscurorum virorum* (1904).

For a complete catalogue of the writings of Hutten, see E. Böcking's *Index Bibliographicus Huttenianus* (1858). Böcking is also the editor of the complete edition of Hutten's works (7 vols., 1859–1862). A selection of Hutten's German writings, edited by G. Balke, appeared in 1891. Cp. S. Szamatolski, *Huttens deutsche Schriften* (1891). The best biography (though it is also somewhat of a political pamphlet) is that of D. F. Strauss (*Ulrich von Hutten*, 1857; 4th ed., 1878; English translation by G. Sturge, 1874), with which may be compared the older monographs by A. Wagenseil (1823), A. Bürck (1846) and J. Zeller (Paris, 1849). See also J. Deckert, *Ulrich von Huttens Leben und Wirken. Eine historische Skizze* (1901). (G. W. K.)

HUTTER, LEONHARD (1563–1616), German Lutheran theologian, was born at Nellingen near Ulm in January 1563. From 1581 he studied at the universities of Strassburg, Leipzig, Heidelberg and Jena. In 1594 he began to give theological lectures at Jena, and in 1596 accepted a call as professor of theology at Wittenberg, where he died on the 23rd of October 1616. Hutter was a stern champion of Lutheran orthodoxy, as set down in the confessions and embodied in his own *Compendium locorum theologicorum* (1610; reprinted 1863), being so faithful to his master as to win the title of "Luther redonatus."

In reply to Rudolf Hospinian's *Concordia discors* (1607), he wrote a work, rich in historical material but one-sided in its apologetics, *Concordia concors* (1614), defending the formula of Concord, which he regarded as inspired. His *Irenicum vere christianum* is directed against David Pareus (1548–1622), professor primarius at Heidelberg, who in *Irenicum sive de unione et synodo Evangelicorum* (1614) had pleaded for a reconciliation of Lutheranism and Calvinism; his *Calvinista aulopoliticus* (1610) was written against the "damnable Calvinism" which was becoming prevalent in Holstein and Brandenburg. Another work, based on the formula of Concord, was entitled *Loci communes theologici.*

HUTTON, CHARLES (1737–1823), English mathematician, was born at Newcastle-on-Tyne on the 14th of August 1737. He was educated in a school at Jesmond, kept by Mr Ivison, a clergyman of the church of England. There is reason to believe, on the evidence of two pay-bills, that for a short time in 1755 and 1756 Hutton worked in Old Long Benton colliery; at any rate, on Ivison's promotion to a living, Hutton succeeded to the Jesmond school, whence, in consequence of increasing pupils, he removed to Stote's Hall. While he taught during the day at Stote's Hall, he studied mathematics in the evening at a school in Newcastle. In 1760 he married, and began tuition on a larger scale in Newcastle, where he had among his pupils John Scott, afterwards Lord Eldon, chancellor of England. In 1764 he published his first work, *The Schoolmaster's Guide, or a Complete System of Practical Arithmetic*, which in 1770 was followed by his *Treatise on Mensuration both in Theory and Practice.* In 1772 appeared a tract on *The Principles of Bridges*, suggested by the destruction of Newcastle bridge by a high flood on the 17th of November 1771. In 1773 he was appointed professor of mathematics at the Royal Military Academy, Woolwich, and in the following year he was elected F.R.S. and reported on Nevil Maskelyne's determination of the mean density and mass of the earth from measurements taken in 1774–1776 at Mount Schiehallion in Perthshire. This account appeared in the *Philosophical Transactions* for 1778, was afterwards reprinted in the second volume of his *Tracts on Mathematical and Philosophical Subjects*, and procured for Hutton the degree of LL.D. from the university of Edinburgh. He was elected foreign secretary to the Royal Society in 1779, but his resignation in 1783 was brought about by the president Sir Joseph Banks, whose behaviour to the mathematical section of the society was somewhat high-handed (see Kippis's *Observations on the late Contests in the Royal Society*, London, 1784). After his *Tables of the Products and Powers of Numbers*, 1781, and his *Mathematical Tables*, 1785, he issued, for the use of the Royal Military Academy, in 1787 *Elements of Conic Sections*, and in 1798 his *Course of Mathematics.* His *Mathematical and Philosophical Dictionary*, a valuable contribution to scientific biography, was published in 1795 (2nd ed., 1815), and the four volumes of *Recreations in Mathematics and Natural Philosophy*, mostly a translation from the French, in 1803. One of the most laborious of his works was the abridgment, in conjunction with G. Shaw and R. Pearson, of the *Philosophical Transactions.* This undertaking, the mathematical and scientific parts of which fell to Hutton's share, was completed in 1809, and filled eighteen volumes quarto. His name first appears in the *Ladies' Diary* (a poetical and mathematical almanac which was begun in 1704, and lasted till 1871) in 1764; ten years later he was appointed editor of the almanac, a post which he retained till 1817. Previously he had begun a small periodical, *Miscellanea Mathematica*, which extended only to thirteen numbers; subsequently he published in five volumes *The Diarian Miscellany*, which contained large extracts from the *Diary.* He resigned his professorship in 1807, and died on the 27th of January 1823.

See John Bruce, *Charles Hutton* (Newcastle, 1823).

HUTTON, JAMES (1726–1797), Scottish geologist, was born in Edinburgh on the 3rd of June 1726. Educated at the high school and university of his native city, he acquired while a student a passionate love of scientific inquiry. He was apprenticed to a lawyer, but his employer advised that a more congenial profession should be chosen for him. The young apprentice chose medicine as being nearest akin to his favourite pursuit of chemistry. He studied for three years at Edinburgh, and completed his medical education in Paris, returning by the Low Countries, and taking his degree of doctor of medicine at Leiden in 1749. Finding, however, that there seemed hardly any opening for him, he abandoned the medical profession, and, having inherited a small property in Berwickshire from his father, resolved to devote himself to agriculture. He then went to Norfolk to learn the practical work of farming, and subsequently travelled in Holland, Belgium and the north of France. During these years he began to study the surface of the earth, gradually shaping in his mind the problem to which he afterwards devoted his energies. In the summer of 1754 he established himself on his own farm in Berwickshire, where he resided for fourteen years, and where he introduced the most improved forms of husbandry. As the farm was brought into excellent order, and as its management, becoming more easy, grew less interesting, he was induced to let it, and establish himself for the rest of his life in Edinburgh. This took place about the year 1768. He was unmarried, and from this period until his death in 1797 he lived with his three sisters. Surrounded by congenial literary and scientific friends he devoted himself to research.

At that time geology in any proper sense of the term did not exist. Mineralogy, however, had made considerable progress. But Hutton had conceived larger ideas than were entertained by the mineralogists of his day. He desired to trace back the origin of the various minerals and rocks, and thus to arrive at some clear understanding of the history of the earth. For many years he continued to study the subject. At last, in the spring of the year 1785, he communicated his views to the recently established Royal Society of Edinburgh in a paper entitled *Theory of the Earth, or an Investigation of the Laws Observable in the Composition, Dissolution and Restoration of Land upon the Globe.* In this remarkable work the doctrine is expounded that geology is not cosmogony, but must confine itself to the study of the materials of the earth; that everywhere evidence may be seen that the present rocks of the earth's surface have been in great part formed out of the waste of older rocks; that these materials having been laid down under the sea were there consolidated under great pressure, and were subsequently disrupted and upheaved by the expansive power of subterranean heat; that during these convulsions veins and masses of molten rock were injected into the rents of the dislocated strata; that every portion of the upraised land, as soon as exposed to the atmosphere, is subject to decay; and that this decay must tend to advance until the whole of the land has been worn away and laid down on the sea-floor, whence future upheavals will once more raise the consolidated sediments into new land. In some of these broad and bold generalizations Hutton was anticipated by the Italian geologists; but to him belongs the credit of having first perceived their mutual relations, and combined them in a luminous coherent theory based upon observation.

It was not merely the earth to which Hutton directed his attention. He had long studied the changes of the atmosphere. The same volume in which his *Theory of the Earth* appeared contained also a *Theory of Rain*, which was read to the Royal Society of Edinburgh in 1784. He contended that the amount of moisture which the air can retain in solution increases with augmentation of temperature, and, therefore, that on the mixture of two masses of air of different temperatures a portion of the moisture must be condensed and appear in visible form. He investigated the available data regarding rainfall and climate in different regions of the globe, and came to the conclusion that the rainfall is everywhere regulated by the humidity of the air on the one hand, and the causes which promote mixtures of different aerial currents in the higher atmosphere on the other.

The vigour and versatility of his genius may be understood from the variety of works which, during his thirty years' residence in Edinburgh, he gave to the world. In 1792 he published a quarto volume entitled *Dissertations on different Subjects in Natural Philosophy*, in which he discussed the nature of matter, fluidity, cohesion, light, heat and electricity. Some of these subjects were further illustrated by him in papers read before the Royal Society of Edinburgh. He did not restrain himself within the domain of physics, but boldly marched into that of metaphysics, publishing three quarto volumes with the title *An Investigation of the Principles of Knowledge, and of the Progress of Reason—from Sense to Science and Philosophy.* In this work he developed the idea that the external world, as conceived by us, is the creation of our own minds influenced by impressions from without, that there is no resemblance between our picture of the outer world and the reality, yet that the impressions produced upon our minds, being constant and consistent, become as much realities to us as if they precisely resembled things actually existing, and, therefore, that our moral conduct must remain the same as if our ideas perfectly corresponded to the causes producing them. His closing years were devoted to the extension and republication of his *Theory of the Earth*, of which two volumes appeared in 1795. A third volume, necessary to complete the work, was left by him in manuscript, and is referred to by his biographer John Playfair. A portion of the MS. of this volume, which had been given to the Geological Society of London by Leonard Horner, was published by the Society in 1899, under the editorship of Sir A. Geikie. The rest of the manuscript appears to be lost. Soon afterwards Hutton set to work to collect and systematize his numerous writings on husbandry, which he proposed to publish under the title of *Elements of Agriculture*. He had nearly completed this labour when an incurable disease brought his active career to a close on the 26th of March 1797.

It is by his *Theory of the Earth* that Hutton will be remembered with reverence while geology continues to be cultivated. The author's style, however, being somewhat heavy and obscure, the book did not attract during his lifetime so much attention as it deserved. Happily for science Hutton numbered among his friends John Playfair (*q.v.*), professor of mathematics in the university of Edinburgh, whose enthusiasm for the spread of Hutton's doctrine was combined with a rare gift of graceful and luminous exposition. Five years after Hutton's death he published a volume, *Illustrations of the Huttonian Theory of the Earth*, in which he gave an admirable summary of that theory, with numerous additional illustrations and arguments. This work is justly regarded as one of the classical contributions to geological literature. To its influence much of the sound progress of British geology must be ascribed. In the year 1805 a biographical account of Hutton, written by Playfair, was published in vol. v. of the *Transactions of the Royal Society of Edinburgh.* (A. Ge.)

HUTTON, RICHARD HOLT (1826–1897), English writer and theologian, son of Joseph Hutton, Unitarian minister at Leeds, was born at Leeds on the 2nd of June 1826. His family removed to London in 1835, and he was educated at University College School and University College, where he began a lifelong friendship with Walter Bagehot, of whose works he afterwards was the editor; he took the degree in 1845, being awarded the gold medal for philosophy. Meanwhile he had also studied for short periods at Heidelberg and Berlin, and in 1847 he entered Manchester New College with the idea of becoming a minister like his father, and studied there under James Martineau. He did not, however, succeed in obtaining a call to any church, and for some little time his future was unsettled. He married in 1851 his cousin, Anne Roscoe, and became joint-editor with J. L. Sanford of the *Inquirer*, the principal Unitarian organ. But his innovations and his unconventional views about stereotyped Unitarian doctrines caused alarm, and in 1853 he resigned. His health had broken down, and he visited the West Indies, where his wife died of yellow fever. In 1855 Hutton and Bagehot became joint-editors of the *National Review*, a new monthly, and conducted it for ten years. During this time Hutton's theological views, influenced largely by Coleridge, and more directly by F. W. Robertson and F. D. Maurice, gradually approached more and more to those of the Church of England, which he ultimately joined. His interest in theology was profound, and he brought to it a spirituality of outlook and an aptitude for metaphysical inquiry and exposition which added a singular attraction to his writings. In 1861 he joined Meredith Townsend as joint-editor and part proprietor of the *Spectator*, then a well-known liberal weekly, which, however, was not remunerative from the business point of view. Hutton took charge of the literary side of the paper, and by degrees his own articles became and remained up to the last one of the best-known features of serious and thoughtful English journalism. The *Spectator*, which gradually became a prosperous property, was his pulpit, in which unwearyingly he gave expression to his views, particularly on literary, religious and philosophical subjects, in opposition to the agnostic and rationalistic opinions then current in intellectual circles, as popularized by Huxley. A man of fearless honesty, quick and catholic sympathies, broad culture, and many friends in intellectual and religious circles, he became one of the most influential journalists of the day, his fine character and conscience earning universal respect and confidence. He was an original member of the Metaphysical Society (1869). He was an anti-vivisectionist, and a member of the royal commission (1875) on that subject. In 1858 he had married Eliza Roscoe, a cousin of his first wife; she died early in 1897, and Hutton's own death followed on the 9th of September of the same year.

Among his other publications may be mentioned *Essays, Theological and Literary* (1871; revised 1888), and *Criticisms on Contemporary Thought and Thinkers* (1894); and his opinions may be studied compendiously in the selections from his *Spectator* articles published in 1899 under the title of *Aspects of Religious and Scientific Thought.*

HUXLEY, THOMAS HENRY (1825–1895), English biologist, was born on the 4th of May 1825 at Ealing, where his father, George Huxley, was senior assistant-master in the school of Dr Nicholas. This was an establishment of repute, and is at any rate remarkable for having produced two men with so little in common in after life as Huxley and Cardinal Newman. The cardinal's brother, Francis William, had been "captain" of the school in 1821. Huxley was a seventh child (as his father had also been), and the youngest who survived infancy. Of Huxley's ancestry no more is ascertainable than in the case of most middle-class families. He himself thought it sprang from the Cheshire Huxleys of Huxley Hall. Different branches migrated south, one, now extinct, reaching London, where its members were apparently engaged in commerce. They established themselves for four generations at Wyre Hall, near Edmonton, and one was knighted by Charles II. Huxley describes his paternal race as "mainly Iberian mongrels, with a good dash of Norman and a little Saxon."[1] From his father he thought he derived little except a quick temper and the artistic faculty which proved of great service to him and reappeared in an even more striking degree in his daughter, the Hon. Mrs Collier. "Mentally and physically," he wrote, "I am a piece of my mother." Her maiden name was Rachel Withers. "She came of Wiltshire people," he adds, and describes her as "a typical example of the Iberian variety." He tells us that "her most distinguishing characteristic was rapidity of thought. . . That peculiarity has been passed on to me in full strength" (*Essays*, i. 4). One of the not least striking facts in Huxley's life is that of education in the formal sense he received none. "I had two years of a pandemonium of a school (between eight and ten), and after that neither help nor sympathy in any intellectual direction till I reached manhood" (*Life*, ii. 145). After the death of Dr Nicholas the Ealing school broke up, and Huxley's father returned about 1835 to his native town, Coventry, where he had obtained a small appointment. Huxley was left to his own devices; few histories of boyhood could offer any parallel. At twelve he was sitting up in bed to read Hutton's *Geology*. His great desire was to be a mechanical engineer; it ended in his devotion to "the mechanical engineering of living machines." His curiosity in this direction was nearly fatal; a *post-mortem* he was taken to between thirteen and fourteen was followed by an illness which seems to have been the starting-point of the ill-health which pursued him all through life. At fifteen he devoured Sir William Hamilton's *Logic*, and thus acquired the taste for metaphysics, which he cultivated to the end. At seventeen he came under the influence of Thomas Carlyle's writings. Fifty years later he wrote: "To make things clear and get rid of cant and shows of all sorts. This was the lesson I learnt from Carlyle's books when I was a boy, and it has stuck by me all my life" (*Life*, ii. 268). Incidentally they led him to begin to learn German; he had already acquired French. At seventeen Huxley, with his elder brother James, commenced regular medical studies at Charing Cross Hospital, where they had both obtained scholarships. He studied under Wharton Jones, a physiologist who never seems to have attained the reputation he deserved. Huxley said of him: "I do not know that I ever felt so much respect for a teacher before or since" (*Life*, i. 20). At twenty he passed his first M.B. examination at the University of London, winning the gold medal for anatomy and physiology; W. H. Ransom, the well-known Nottingham physician, obtaining the exhibition. In 1845 he published, at the suggestion of Wharton Jones, his first scientific paper, demonstrating the existence of a hitherto unrecognized layer in the inner sheath of hairs, a layer that has been known since as "Huxley's layer."

[1] *Nature*, lxiii. 127.

Something had to be done for a livelihood, and at the suggestion of a fellow-student, Mr (afterwards Sir Joseph) Fayrer, he applied for an appointment in the navy. He passed the necessary examination, and at the same time obtained the qualification of the Royal College of Surgeons. He was "entered on the books of Nelson's old ship, the 'Victory,' for duty at Haslar Hospital." Its chief, Sir John Richardson, who was a well-known Arctic explorer and naturalist, recognized Huxley's ability, and procured for him the post of surgeon to H.M.S. "Rattlesnake," about to start for surveying work in Torres Strait. The commander, Captain Owen Stanley, was a son of the bishop of Norwich and brother of Dean Stanley, and wished for an officer with some scientific knowledge. Besides Huxley the "Rattlesnake" also carried a naturalist by profession, John Macgillivray, who, however, beyond a dull narrative of the expedition, accomplished nothing. The "Rattlesnake" left England on the 3rd of December 1846, and was ordered home after the lamented death of Captain Stanley at Sydney, to be paid off at Chatham on the 9th of November 1850. The tropical seas teem with delicate surface-life, and to the study of this Huxley devoted himself with unremitting devotion. At that time no known methods existed by which it could be preserved for study in museums at home. He gathered a magnificent harvest in the almost unreaped field, and the conclusions he drew from it were the beginning of the revolution in zoological science which he lived to see accomplished.

Baron Cuvier (1769–1832), whose classification still held its ground, had divided the animal kingdom into four great *embranchements*. Each of these corresponded to an independent archetype, of which the "idea" had existed in the mind of the Creator. There was no other connexion between these classes, and the "ideas" which animated them were, as far as one can see, arbitrary. Cuvier's groups, without their theoretical basis, were accepted by K. E. von Baer (1792–1876). The "idea" of the group, or archetype, admitted of endless variation within it; but this was subordinate to essential conformity with the archetype, and hence Cuvier deduced the important principle of the "correlation of parts," of which he made such conspicuous use in palaeontological reconstruction. Meanwhile the "Naturphilosophen," with J. W. Goethe (1749–1832) and L. Oken (1779–1851), had in effect grasped the underlying principle of correlation, and so far anticipated evolution by asserting the possibility of deriving specialized from simpler structures. Though they were still hampered by idealistic conceptions, they established morphology. Cuvier's four great groups were Vertebrata, Mollusca, Articulata and Radiata.

It was amongst the members of the last class that Huxley found most material ready to his hand in the seas of the tropics. It included organisms of the most varied kind, with nothing more in common than that their parts were more or less distributed round a centre. Huxley sent home "communication after communication to the Linnean Society," then a somewhat somnolent body, "with the same result as that obtained by Noah when he sent the raven out of the ark" (*Essays*, i. 13). His important paper, *On the Anatomy and the Affinities of the Family of Medusae*, met with a better fate. It was communicated by the bishop of Norwich to the Royal Society, and printed by it in the *Philosophical Transactions* in 1849. Huxley united, with the Medusae, the Hydroid and Sertularian polyps, to form a class to which he subsequently gave the name of Hydrozoa. This alone was no inconsiderable feat for a young surgeon who had only had the training of the medical school. But the ground on which it was done has led to far-reaching theoretical developments. Huxley realized that something more than superficial characters were necessary in determining the affinities of animal organisms. He found that all the members of the class consisted of two membranes enclosing a central cavity or stomach. This is characteristic of what are now called the Coelenterata. All animals higher than these have been termed Coelomata; they possess a distinct body-cavity in addition to the stomach. Huxley went further than this, and the most profound suggestion in his paper is the comparison of the two layers with those which appear in the germ of the higher animals. The consequences which have flowed from this prophetic generalization of the *ectoderm* and *endoderm* are familiar to every student of evolution. The conclusion was the more remarkable as at the time he was not merely free from any evolutionary belief, but actually rejected it. The value of Huxley's work was immediately recognized. On returning to England in 1850 he was elected a Fellow of the Royal Society. In the following year, at the age of twenty-six, he not merely received the Royal medal, but was elected on the council. With absolutely no aid from any one he had placed himself in the front rank of English scientific men. He secured the friendship of Sir J. D. Hooker and John Tyndall, who remained his lifelong friends. The Admiralty retained him as a nominal assistant-surgeon, in order that he might work up the observations he had made during the voyage of the "Rattlesnake." He was thus enabled to produce various important memoirs, especially those on certain Ascidians, in which he solved the problem of *Appendicularia*—an organism whose place in the animal kingdom Johannes Müller had found himself wholly unable to assign—and on the morphology of the Cephalous Mollusca.

Richard Owen, then the leading comparative anatomist in Great Britain, was a disciple of Cuvier, and adopted largely from him the deductive explanation of anatomical fact from idealistic conceptions. He superadded the evolutionary theories of Oken, which were equally idealistic, but were altogether repugnant to Cuvier. Huxley would have none of either. Imbued with the methods of von Baer and Johannes Müller, his methods were purely inductive. He would not hazard any statement beyond what the facts revealed. He retained, however, as has been done by his successors, the use of archetypes, though they no longer represented fundamental "ideas" but generalizations of the essential points of structure common to the individuals of each class. He had not wholly freed himself, however, from archetypal trammels. "The doctrine," he says, "that every natural group is organized after a definite archetype . . . seems to me as important for zoology as the doctrine of definite proportions for chemistry." This was in 1853. He further stated: "There is no progression from a lower to a higher type, but merely a more or less complete evolution of one type" (*Phil. Trans.*, 1853, p. 63). As Chalmers Mitchell points out, this statement is of great historical interest. Huxley definitely uses the word "evolution," and admits its existence *within* the great groups. He had not, however, rid himself of the notion that the archetype was a property inherent in the group. Herbert Spencer, whose acquaintance he made in 1852, was unable to convert him to evolution in its widest sense (*Life*, i. 168). He could not bring himself to acceptance of the theory—owing, no doubt, to his rooted aversion from à priori reasoning—without a mechanical conception of its mode of operation. In his first interview with Darwin, which seems to have been about the same time, he expressed his belief "in the sharpness of the lines of demarcation between natural groups," and was received with a humorous smile (*Life*, i. 169).

The naval medical service exists for practical purposes. It is not surprising, therefore, that after his three years' nominal employment Huxley was ordered on active service. Though without private means of any kind, he resigned. The navy, however, retains the credit of having started his scientific career as well as that of Hooker and Darwin. Huxley was now thrown on his own resources, the immediate prospects of which were slender enough. As a matter of fact, he had not to wait many months. His friend, Edward Forbes, was appointed to the chair of natural history in Edinburgh, and in July 1854 he succeeded him as lecturer at the School of Mines and as naturalist to the Geological Survey in the following year. The latter post he hesitated at first to accept, as he "did not care for fossils" (*Essays*, i. 15). In 1855 he married Miss H. A. Heathorn, whose acquaintance he had made in Sydney. They were engaged when Huxley could offer nothing but the future promise of his ability. The confidence of his devoted helpmate was not misplaced, and her affection sustained him to the end, after she had seen him the recipient of every honour which English science could bestow. His most important research belonging to this period was the Croonian Lecture delivered before the Royal Society in 1858 on "The Theory of the Vertebrate Skull." In this he completely and finally demolished, by applying as before the inductive method, the idealistic, if in some degree evolutionary, views of its origin which Owen had derived from Goethe and Oken. This finally disposed of the "archetype," and may be said once for all to have liberated the English anatomical school from the deductive method.

In 1859 *The Origin of Species* was published. This was a momentous event in the history of science, and not least for Huxley. Hitherto he had turned a deaf ear to evolution. "I took my stand," he says, "upon two grounds: firstly, that . . . the evidence in favour of transmutation was wholly insufficient; and secondly, that no suggestion respecting the causes of the transmutation assumed, which had been made, was in any way adequate to explain the phenomena" (*Life*, i. 168). Huxley had studied Lamarck "attentively," but to no purpose. Sir Charles Lyell "was the chief agent in smoothing the road for Darwin. For consistent uniformitarianism postulates evolution as much in the organic as in the inorganic world" (*l.c.*); and Huxley found in Darwin what he had failed to find in Lamarck, an intelligible hypothesis good enough as a working basis. Yet with the transparent candour which was characteristic of him, he never to the end of his life concealed the fact that he thought it wanting in rigorous proof. Darwin, however, was a naturalist; Huxley was not. He says: "I am afraid there is very little of the genuine naturalist in me. I never collected anything, and species-work was always a burden to me; what I cared for was the architectural and engineering part of the business" (*Essays*, i. 7). But the solution of the problem of organic evolution must work upwards from the initial stages, and it is precisely for the study of these that "species-work" is necessary. Darwin, by observing the peculiarities in the distribution of the plants which he had collected in the Galapagos, was started on the path that led to his theory. Anatomical research had only so far led to transcendental hypothesis, though in Huxley's hands it had cleared the decks of that lumber. He quotes with approval Darwin's remark that "no one has a right to examine the question of species who has not minutely described many" (*Essays*, ii. 283). The rigorous proof which Huxley demanded was the production of species sterile to one another by selective breeding (*Life*, i. 193). But this was a misconception of the question. Sterility is a physiological character, and the specific differences which the theory undertook to account for are morphological; there is no necessary nexus between the two. Huxley, however, felt that he had at last a secure grip of evolution. He warned Darwin: "I will stop at no point as long as clear reasoning will carry me further" (*Life*, i. 172). Owen, who had some evolutionary tendencies, was at first favourably disposed to Darwin's theory, and even claimed that he had to some extent anticipated it in his own writings. But Darwin, though he did not thrust it into the foreground, never flinched from recognizing that man could not be excluded from his theory. "Light will be thrown on the origin of man and his history" (*Origin*, ed. i. 488). Owen could not face the wrath of fashionable orthodoxy. In his Rede Lecture he endeavoured to save the position by asserting that man was clearly marked off from all other animals by the anatomical structure of his brain. This was actually inconsistent with known facts, and was effectually refuted by Huxley in various papers and lectures, summed up in 1863 in *Man's Place in Nature*. This "monkey damnification" of mankind was too much even for the "veracity" of Carlyle, who is said to have never forgiven it. Huxley had not the smallest respect for authority as a basis for belief, scientific or otherwise. He held that scientific men were morally bound "to try all things and hold fast to that which is good" (*Life*, ii. 161). Called upon in 1862, in the absence of the president, to deliver the presidential address to the Geological Society, he disposed once for all of one of the principles accepted by geologists, that similar fossils in distinct regions indicated that the strata containing them were contemporary. All that could be concluded, he pointed out, was that the general order of succession was the same. In 1854 Huxley had refused the post of palaeontologist to the Geological Survey; but the fossils for which he then said that he "did not care" soon acquired importance in his eyes, as supplying evidence for the support of the evolutionary theory. The thirty-one years during which he occupied the chair of natural history at the School of Mines were largely occupied with palaeontological research. Numerous memoirs on fossil fishes established many far-reaching morphological facts. The study of fossil reptiles led to his demonstrating, in the course of lectures on birds, delivered at the College of Surgeons in 1867, the fundamental affinity of the two groups which he united under the title of Sauropsida. An incidental result of the same course was his proposed rearrangement of the zoological regions into which P. L. Sclater had divided the world in 1857. Huxley anticipated, to a large extent, the results at which botanists have since arrived: he proposed as primary divisions, Arctogaea—to include the land areas of the northern hemisphere—and Notogaea for the remainder. Successive waves of life originated in and spread from the northern area, the survivors of the more ancient types finding successively a refuge in the south. Though Huxley had accepted the Darwinian theory as a working hypothesis, he never succeeded in firmly grasping it in detail. He thought "evolution might conceivably have taken place without the development of groups possessing the characters of species" (*Essays*, v. 41). His palaeontological researches ultimately led him to dispense with Darwin. In 1892 he wrote: "The doctrine of evolution is no speculation, but a generalization of certain facts . . . classed by biologists under the heads of Embryology and of Palaeontology" (*Essays*, v. 42). Earlier in 1881 he had asserted even more emphatically that if the hypothesis of evolution "had not existed, the palaeontologist would have had to invent it" (*Essays*, iv. 44).

From 1870 onwards he was more and more drawn away from scientific research by the claims of public duty. Some men yield the more readily to such demands, as their fulfilment is not unaccompanied by public esteem. But he felt, as he himself said of Joseph Priestley, "that he was a man and a citizen before he was a philosopher, and that the duties of the two former positions are at least as imperative as those of the latter" (*Essays*, iii. 13). From 1862 to 1884 he served on no less than ten Royal Commissions, dealing in every case with subjects of great importance, and in many with matters of the gravest moment to the community. He held and filled with invariable dignity and distinction more public positions than have perhaps ever fallen to the lot of a scientific man in England. From 1871 to 1880 he was a secretary of the Royal Society. From 1881 to 1885 he was president. For honours he cared little, though they were within his reach; it is said that he might have received a peerage. He accepted, however, in 1892, a Privy Councillorship, at once the most democratic and the most aristocratic honour accessible to an English citizen. In 1870 he was president of the British Association at Liverpool, and in the same year was elected a member of the newly constituted London School Board. He resigned the latter position in 1872, but in the brief period during which he acted, probably more than any man, he left his mark on the foundations of national elementary education. He made war on the scholastic methods which wearied the mind in merely taxing the memory; the children were to be prepared to take their place worthily in the community. Physical training was the basis; domestic economy, at any rate for girls, was insisted upon, and for all some development of the aesthetic sense by means of drawing and singing. Reading, writing and arithmetic were the indispensable tools for acquiring knowledge, and intellectual discipline was to be gained through the rudiments of physical science. He insisted on the teaching of the Bible partly as a great literary heritage, partly because he was "seriously perplexed to know by what practical measures the religious feeling, which is the essential basis of conduct, was to be kept up, in the present utterly chaotic state of opinion in these matters, without its use" (*Essays*, iii. 397). In 1872 the School of Mines was moved to South Kensington, and Huxley had, for the first time after eighteen years, those appliances for teaching beyond the lecture room, which to the lasting injury of the interests of biological science in Great Britain had been withheld from him by the short-sightedness of government. Huxley had only been able to bring his influence to bear upon his pupils by oral teaching, and had had no opportunity by personal intercourse in the laboratory of forming a school. He was now able to organize a system of instruction for classes of elementary teachers in the general principles of biology, which indirectly affected the teaching of the subject throughout the country.

The first symptoms of physical failure to meet the strain of the scientific and public duties demanded of him made some rest imperative, and he took a long holiday in Egypt. He still continued for some years to occupy himself mainly with vertebrate morphology. But he seemed to find more interest and the necessary mental stimulus to exertion in lectures, public addresses and more or less controversial writings. His health, which had for a time been fairly restored, completely broke down again in 1885. In 1890 he removed from London to Eastbourne, where after a painful illness he died on the 29th of June 1895.

The latter years of Huxley's life were mainly occupied with contributions to periodical literature on subjects connected with philosophy and theology. The effect produced by these on popular opinion was profound. This was partly due to his position as a man of science, partly to his obvious earnestness and sincerity, but in the main to his strenuous and attractive method of exposition. Such studies were not wholly new to him, as they had more or less engaged his thoughts from his earliest days. That his views exhibit some process of development and are not wholly consistent was, therefore, to be expected, and for this reason it is not easy to summarize them as a connected body of teaching. They may be found perhaps in their most systematic form in the volume on *Hume* published in 1879.

Huxley's general attitude to the problems of theology and philosophy was technically that of scepticism. "I am," he wrote, "too much of a sceptic to deny the possibility of anything" (*Life*, ii. 127). "Doubt is a beneficent demon" (*Essays*, ix. 56). He was anxious, nevertheless, to avoid the accusation of Pyrrhonism (*Life*, ii. 280), but the Agnosticism which he defined to express his position in 1869 suggests the Pyrrhonist *Aphasia*. The only approach to certainty which he admitted lay in the order of nature. "The conception of the constancy of the order of nature has become the dominant idea of modern thought. . . . Whatever may be man's speculative doctrines, it is quite certain that every intelligent person guides his life and risks his fortune upon the belief that the order of nature is constant, and that the chain of natural causation is never broken." He adds, however, that "it by no means necessarily follows that we are justified in expanding this generalization into the infinite past" (*Essays*, iv. 47, 48). This was little more than a pious reservation, as evolution implies the principle of continuity (*l.c.* p. 55). Later he stated his belief even more absolutely: "If there is anything in the world which I do firmly believe in, it is the universal validity of the law of causation, but that universality cannot be proved by any amount of experience" (*Essays*, ix. 121). The assertion that "There is only one method by which intellectual truth can be reached, whether the subject-matter of investigation belongs to the world of physics or to the world of consciousness" (*Essays*, ix. 126) laid him open to the charge of materialism, which he vigorously repelled. His defence, when he rested it on the imperfection of the physical analysis of matter and force (*l.c.* p. 131), was irrelevant; he was on sounder ground when he contended with Berkeley "that our certain knowledge does not extend beyond our states of consciousness" (*l.c.* p. 130). "Legitimate materialism, that is, the extension of the conceptions and of the methods of physical science to the highest as well as to the lowest phenomena of vitality, is neither more nor less than a sort of shorthand idealism" (*Essays*, i. 194). While "the substance of matter is a metaphysical unknown quality of the existence of which there is no proof . . . the non-existence of a substance of mind is equally arguable; . . . the result . . . is the reduction of the All to co-existences and sequences of phenomena beneath and beyond which there is nothing cognoscible" (*Essays*, ix. 66). Hume had defined a miracle as a "violation of the laws of nature." Huxley refused to accept this. While, on the one hand, he insists that "the whole fabric of practical life is built upon our faith in its continuity" (*Hume*, p. 129), on the other "nobody can presume to say what the order of nature must be"; this "knocks the bottom out of all a priori objections either to ordinary 'miracles' or to the efficacy of prayer" (*Essays*, v. 133). "If by the term miracles we mean only extremely wonderful events, there can be no just ground for denying the possibility of their occurrence" (*Hume*, p. 134). Assuming the chemical elements to be aggregates of uniform primitive matter, he saw no more theoretical difficulty in water being turned into alcohol in the miracle at Cana, than in sugar undergoing a similar conversion (*Essays*, v. 81). The credibility of miracles with Huxley is a question of evidence. It may be remarked that a scientific explanation is destructive of the supernatural character of a miracle, and that the demand for evidence may be so framed as to preclude the credibility of any historical event. Throughout his life theology had a strong attraction, not without elements of repulsion, for Huxley. The circumstances of his early training, when Paley was the "most interesting Sunday reading allowed him when a boy" (*Life*, ii. 57), probably had something to do with both. In 1860 his beliefs were apparently theistic: "Science seems to me to teach in the highest and strongest manner the great truth which is embodied in the Christian conception of entire surrender to the will of God" (*Life*, i. 219). In 1885 he formulates "the perfect ideal of religion" in a passage which has become almost famous: "In the 8th century B.C. in the heart of a world of idolatrous polytheists, the Hebrew prophets put forth a conception of religion which appears to be as wonderful an inspiration of genius as the art of Pheidias or the science of Aristotle. 'And what doth the Lord require of thee, but to do justly, and to love mercy, and to walk humbly with thy God'" (*Essays*, iv. 161). Two years later he was writing: "That there is no evidence of the existence of such a being as the God of the theologians is true enough" (*Life*, ii. 162). He insisted, however, that "atheism is on purely philosophical grounds untenable" (*l.c.*). His theism never really advanced beyond the recognition of "the passionless impersonality of the unknown and unknowable, which science shows everywhere underlying the thin veil of phenomena" (*Life*, i. 239). In other respects his personal creed was a kind of scientific Calvinism. There is an interesting passage in an essay written in 1892, "An Apologetic Eirenicon," which has not been republished, which illustrates this: "It is the secret of the superiority of the best theological teachers to the majority of their opponents that they substantially recognize these realities of things, however strange the forms in which they clothe their conceptions. The doctrines of predestination, of original sin, of the innate depravity of man and the evil fate of the greater part of the race, of the primacy of Satan in this world, of the essential vileness of matter, of a malevolent Demiurgus subordinate to a benevolent Almighty, who has only lately revealed himself, faulty as they are, appear to me to be vastly nearer the truth than the 'liberal' popular illusions that babies are all born good, and that the example of a corrupt society is responsible for their failure to remain so; that it is given to everybody to reach the ethical ideal if he will only try; that all partial evil is universal good, and other optimistic figments, such as that which represents 'Providence' under the guise of a paternal philanthropist, and bids us believe that everything will come right (according to our notions) at last." But his "slender definite creed," R. H. Hutton, who was associated with him in the Metaphysical Society, thought—and no doubt rightly—in no respect "represented the cravings of his larger nature."

From 1880 onwards till the very end of his life, Huxley was continuously occupied in a controversial campaign against orthodox beliefs. As Professor W. F. R. Weldon justly said of his earlier polemics: "They were certainly among the principal agents in winning a larger measure of toleration for the critical examination of fundamental beliefs, and for the free expression of honest reverent doubt." He threw Christianity overboard bodily and with little appreciation of its historic effect as a civilizing agency. He thought that "the exact nature of the teachings and the convictions of Jesus is extremely uncertain" (*Essays*, v. 348). "What we are usually pleased to call religion nowadays is, for the most part, Hellenized Judaism" (*Essays*, iv. 162). His final analysis of what "since the second century, has assumed to itself the title of Orthodox Christianity" is a "varying compound of some of the best and some of the worst elements of Paganism and Judaism, moulded in practice by the innate character of certain people of the Western world" (*Essays*, v. 142). He concludes "That this Christianity is doomed to fall is, to my mind, beyond a doubt; but its fall will neither be sudden nor speedy" (*l.c.*). He did not omit, however, to do justice to "the bright side of Christianity," and was deeply impressed with the life of Catherine of Siena. Failing Christianity, he thought that some other "hypostasis of men's hopes" will arise (*Essays*, v. 254). His latest speculations on ethical problems are perhaps the least satisfactory of his writings. In 1892 he wrote: "The moral sense is a very complex affair—dependent in part upon associations of pleasure and pain, approbation and disapprobation, formed by education in early youth, but in part also on an innate sense of moral beauty and ugliness (how originated need not be discussed), which is possessed by some people in great strength, while some are totally devoid of it" (*Life*, ii. 305). This is an intuitional theory, and he compares the moral with the aesthetic sense, which he repeatedly declares to be intuitive; thus: "All the understanding in the world will neither increase nor diminish the force of the intuition that this is beautiful and this is ugly" (*Essays*, ix. 80). In the Romanes Lecture delivered in 1894, in which this passage occurs, he defines "law and morals" to be "restraints upon the struggle for existence between men in society." It follows that "the ethical process is in opposition to the cosmic process," to which the struggle for existence belongs (*Essays*, ix. 31). Apparently he thought that the moral sense in its origin was intuitional and in its development utilitarian. "Morality commenced with society" (*Essays*, v. 52). The "ethical process" is the "gradual strengthening of the social bond" (*Essays*, ix. 35). "The cosmic process has no sort of relation to moral ends" (*l.c.* p. 83); "of moral purpose I see no trace in nature. That is an article of exclusive human manufacture" (*Life*, ii. 268). The cosmic process Huxley identified with evil, and the ethical process with good; the two are in necessary conflict. "The reality at the bottom of the doctrine of original sin" is the "innate tendency to self-assertion" inherited by man from the cosmic order (*Essays*, ix. 27). "The actions we call sinful are part and parcel of the struggle for existence" (*Life*, ii. 282). "The prospect of attaining untroubled happiness" is "an illusion" (*Essays*, ix. 44), and the cosmic process in the long run will get the best of the contest, and "resume its sway" when evolution enters on its downward course (*l.c.* p. 45). This approaches pure pessimism, and though in Huxley's view the "pessimism of Schopenhauer is a nightmare" (*Essays*, ix. 200), his own philosophy of life is not distinguishable, and is often expressed in the same language. The cosmic order is obviously non-moral (*Essays*, ix. 197). That it is, as has been said, immoral is really meaningless. Pain and suffering are affections which imply a complex nervous organization, and we are not justified in projecting them into nature external to ourselves. Darwin and A. R. Wallace disagreed with Huxley in seeing rather the joyous than the suffering side of nature. Nor can it be assumed that the descending scale of evolution will reproduce the ascent, or that man will ever be conscious of his doom.

As has been said, Huxley never thoroughly grasped the Darwinian principle. He thought "transmutation may take place without transition" (*Life*, i. 173). In other words, that evolution is accomplished by leaps and not by the accumulation of small variations. He recognized the "struggle for existence" but not the gradual adjustment of the organism to its environment which is implied in "natural selection." In highly civilized societies he thought that the former was at an end (*Essays*, ix. 36) and had been replaced by the "struggle for enjoyment" (*l.c.* p. 40). But a consideration of the stationary population of France might have shown him that the effect in the one case may be as restrictive as in the other. So far from natural selection being in abeyance under modern social conditions, "it is," as Professor Karl Pearson points out, "something we run up against at once, almost as soon as we examine a mortality table" (*Biometrika*, i. 76). The inevitable conclusion, whether we like it or not, is that the future evolution of humanity is as much a part of the cosmic process as its past history, and Huxley's attempt to shut the door on it cannot be maintained scientifically.

Huxley (9 vols., 1898); *Thomas Henry Huxley, a Sketch of his Life and Work*, by P. Chalmers Mitchell, M.A. (Oxon., 1900); a critical study founded on careful research and of great value. (W. T. T.-D.)

HUY (Lat. *Hoium*, and Flem. *Hoey*), a town of Belgium, on the right bank of the Meuse, at the point where it is joined by the Hoyoux. Pop. (1904), 14,164. It is 19 m. E. of Namur and a trifle less west of Liége. Huy certainly dates from the 7th century, and, according to some, was founded by the emperor

Antoninus in A.D. 148. Its situation is striking, with its grey citadel crowning a grey rock, and the fine collegiate church (with a 13th-century gateway) of Notre Dame built against it. The citadel is now used partly as a depot of military equipment and partly as a prison. The ruins are still shown of the abbey of Neumoustier founded by Peter the Hermit on his return from the first crusade. He was buried there in 1115, and a statue was erected to his memory in the abbey grounds in 1858. Neumoustier was one of seventeen abbeys in this town alone dependent on the bishopric of Liége. Huy is surrounded by vineyards, and the bridge which crosses the Meuse at this point connects the fertile Hesbaye north of the river with the rocky and barren Condroz south of it.

HUYGENS, CHRISTIAAN (1629–1695), Dutch mathematician, mechanician, astronomer and physicist, was born at the Hague on the 14th of April 1629. He was the second son of Sir Constantijn Huygens. From his father he received the rudiments of his education, which was continued at Leiden under A. Vinnius and F. van Schooten, and completed in the juridical school of Breda. His mathematical bent, however, soon diverted him from legal studies, and the perusal of some of his earliest theorems enabled Descartes to predict his future greatness. In 1649 he accompanied the mission of Henry, count of Nassau, to Denmark, and in 1651 entered the lists of science as an assailant of the unsound system of quadratures adopted by Gregory of St Vincent. This first essay (*Exetasis quadraturae circuli*, Leiden, 1651) was quickly succeeded by his *Theoremata de quadratura hyperboles, ellipsis, et circuli*; while, in a treatise entitled *De circuli magnitudine inventa*, he made, three years later, the closest approximation so far obtained to the ratio of the circumference to the diameter of a circle.

Another class of subjects was now to engage his attention. The improvement of the telescope was justly regarded as a *sine qua non* for the advancement of astronomical knowledge. But the difficulties interposed by spherical and chromatic aberration had arrested progress in that direction until, in 1655, Huygens, working with his brother Constantijn, hit upon a new method of grinding and polishing lenses. The immediate results of the clearer definition obtained were the detection of a satellite to Saturn (the sixth in order of distance from its primary), and the resolution into their true form of the abnormal appendages to that planet. Each discovery in turn was, according to the prevailing custom, announced to the learned world under the veil of an anagram—removed, in the case of the first, by the publication, early in 1656, of the little tract *De Saturni luna observatio nova*; but retained, as regards the second, until 1659, when in the *Systema Saturnium* the varying appearances of the so-called "triple planet" were clearly explained as the phases of a ring inclined at an angle of 28° to the ecliptic. Huygens was also in 1656 the first effective observer of the Orion nebula; he delineated the bright region still known by his name, and detected the multiple character of its nuclear star. His application of the pendulum to regulate the movement of clocks sprang from his experience of the need for an exact measure of time in observing the heavens. The invention dates from 1656; on the 16th of June 1657 Huygens presented his first "pendulum-clock" to the states-general; and the *Horologium*, containing a description of the requisite mechanism, was published in 1658.

His reputation now became cosmopolitan. As early as 1655 the university of Angers had distinguished him with an honorary degree of doctor of laws. In 1663, on the occasion of his second visit to England, he was elected a fellow of the Royal Society, and imparted to that body in January 1669 a clear and concise statement of the laws governing the collision of elastic bodies. Although these conclusions were arrived at independently, and, as it would seem, several years previous to their publication, they were in great measure anticipated by the communications on the same subject of John Wallis and Christopher Wren, made respectively in November and December 1668.

Huygens had before this time fixed his abode in France. In 1665 Colbert made to him on behalf of Louis XIV. an offer too tempting to be refused, and between the following year and 1681 his residence in the philosophic seclusion of the Bibliothèque du Roi was only interrupted by two short visits to his native country. His *magnum opus* dates from this period. The *Horologium oscillatorium*, published with a dedication to his royal patron in 1673, contained original discoveries sufficient to have furnished materials for half a dozen striking disquisitions. His solution of the celebrated problem of the "centre of oscillation" formed in itself an important event in the history of mechanics. Assuming as an axiom that the centre of gravity of any number of interdependent bodies cannot rise higher than the point from which it fell, he arrived, by anticipating in the particular case the general principle of the conservation of *vis viva*, at correct although not strictly demonstrated conclusions. His treatment of the subject was the first successful attempt to deal with the dynamics of a system. The determination of the true relation between the length of a pendulum and the time of its oscillation; the invention of the theory of evolutes; the discovery, hence ensuing, that the cycloid is its own evolute, and is strictly isochronous; the ingenious although practically inoperative idea of correcting the "circular error" of the pendulum by applying cycloidal cheeks to clocks—were all contained in this remarkable treatise. The theorems on the composition of forces in circular motion with which it concluded formed the true prelude to Newton's *Principia*, and would alone suffice to establish the claim of Huygens to the highest rank among mechanical inventors.

In 1681 he finally severed his French connexions, and returned to Holland. The harsher measures which about that time began to be adopted towards his co-religionists in France are usually assigned as the motive of this step. He now devoted himself during six years to the production of lenses of enormous focal distance, which, mounted on high poles, and connected with the eye-piece by means of a cord, formed what were called "aerial telescopes." Three of his object-glasses, of respectively 123, 180 and 210 ft. focal length, are in the possession of the Royal Society. He also succeeded in constructing an almost perfectly achromatic eye-piece, still known by his name. But his researches in physical optics constitute his chief title-deed to immortality. Although Robert Hooke in 1668 and Ignace Pardies in 1672 had adopted a vibratory hypothesis of light, the conception was a mere floating possibility until Huygens provided it with a sure foundation. His powerful scientific imagination enabled him to realize that all the points of a wave-front originate partial waves, the aggregate effect of which is to reconstitute the primary disturbance at the subsequent stages of its advance, thus accomplishing its propagation; so that each primary undulation is the envelope of an indefinite number of secondary undulations. This resolution of the original wave is the well-known "Principle of Huygens," and by its means he was enabled to prove the fundamental laws of optics, and to assign the correct construction for the direction of the extraordinary ray in uniaxial crystals. These investigations, together with his discovery of the "wonderful phenomenon" of polarization, are recorded in his *Traité de la lumière*, published at Leiden in 1690, but composed in 1678. In the appended treatise *Sur la Cause de la pesanteur*, he rejected gravitation as a universal quality of matter, although admitting the Newtonian theory of the planetary revolutions. From his views on centrifugal force he deduced the oblate figure of the earth, estimating its compression, however, at little more than one-half its actual amount.

Huygens never married. He died at the Hague on the 8th of June 1695, bequeathing his manuscripts to the university of Leiden, and his considerable property to the sons of his younger brother. In character he was as estimable as he was brilliant in intellect. Although, like most men of strong originative power, he assimilated with difficulty the ideas of others, his tardiness sprang rather from inability to depart from the track of his own methods than from reluctance to acknowledge the merits of his competitors.

In addition to the works already mentioned, his *Cosmotheoros*—

a speculation concerning the inhabitants of the planets—was printed posthumously at the Hague in 1698, and appeared almost simultaneously in an English translation. A volume entitled *Opera posthuma* (Leiden, 1703) contained his "Dioptrica," in which the ratio between the respective focal lengths of object-glass and eye-glass is given as the measure of magnifying power, together with the shorter essays *De vitris figurandis, De corona et parheliis*, &c. An early tract *De ratiociniis in ludo aleae*, printed in 1657 with Schooten's *Exercitationes mathematicae*, is notable as one of the first formal treatises on the theory of probabilities; nor should his investigations of the properties of the cissoid, logarithmic and catenary curves be left unnoticed. His invention of the spiral watch-spring was explained in the *Journal des savants* (Feb. 25, 1675). An edition of his works was published by G. J. 's Gravesande, in four quarto volumes entitled *Opera varia* (Leiden, 1724) and *Opera reliqua* (Amsterdam, 1728). His scientific correspondence was edited by P. J. Uylenbroek from manuscripts preserved at Leiden, with the title *Christiani Hugenii aliorumque seculi XVII. virorum celebrium exercitationes mathematicae et philosophicae* (the Hague, 1833).

The publication of a monumental edition of the letters and works of Huygens was undertaken at the Hague by the *Société Hollandaise des Sciences*, with the heading *Œuvres de Christian Huygens* (1888), &c. Ten quarto volumes, comprising the whole of his correspondence, had already been issued in 1905. A biography of Huygens was prefixed to his *Opera varia* (1724); his *Éloge* in the character of a French academician was printed by J. A. N. Condorcet in 1773. Consult further: P. J. HUYGENS, SIR CONSTANTIJN (1596–1687), Dutch poet and diplomatist, was born at the Hague on the 4th of September 1596. His father, Christiaan Huygens, was secretary to the state council, and a man of great political importance. At the baptism of the child, the city of Breda was one of his sponsors, and the admiral Justinus van Nassau the other. He was trained in every polite accomplishment, and before he was seven could speak French with fluency. He was taught Latin by Johannes Dedelus, and soon became a master of classic versification. He developed not only extraordinary intellectual gifts but great physical beauty and strength, and was one of the most accomplished athletes and gymnasts of his age; his skill in playing the lute and in the arts of painting and engraving attracted general attention before he began to develop his genius as a writer. In 1616 he proceeded, with his elder brother, to the university of Leiden. He stayed there only one year, and in 1618 went to London with the English ambassador Dudley Carleton; he remained in London for some months, and then went to Oxford, where he studied for some time in the Bodleian Library, and to Woodstock, Windsor and Cambridge; he was introduced at the English court, and played the lute before James I. The most interesting feature of this visit was the intimacy which sprang up between the young Dutch poet and Dr Donne, for whose genius Huygens preserved through life an unbounded admiration. He returned to Holland in company with the English contingent of the synod of Dort, and in 1619 he proceeded to Venice in the diplomatic service of his country; on his return he nearly lost his life by a foolhardy exploit, namely, the scaling of the topmost spire of Strassburg cathedral. In 1621 he published one of his most weighty and popular poems, his *Batava Tempe*, and in the same year he proceeded again to London, as secretary to the ambassador, Wijngaerdan, but returned in three months. His third diplomatic visit to England lasted longer, from the 5th of December 1621 to the 1st of March 1623. During his absence, his volume of satires, *'t Costelick Mal*, dedicated to Jacob Cats, appeared at the Hague. In the autumn of 1622 he was knighted by James I. He published a large volume of miscellaneous poems in 1625 under the title of *Otiorum libri sex*; and in the same year he was appointed private secretary to the stadholder. In 1627 Huygens married Susanna van Baerle, and settled at the Hague; four sons and a daughter were born to them. In 1630 Huygens was called to a seat in the privy council, and he continued to exercise political power with wisdom and vigour for many years, under the title of the lord of Zuylichem. In 1634 he is supposed to have completed his long-talked-of version of the poems of Donne, fragments of which exist. In 1637 his wife died, and he immediately began to celebrate the virtues and pleasures of their married life in the remarkable didactic poem called *Dagwerck*, which was not published till long afterwards. From 1639 to 1641 he occupied himself by building a magnificent house and garden outside the Hague, and by celebrating their beauties in a poem entitled *Hofwijck*, which was published in 1653. In 1647 he wrote his beautiful poem of *Oogentroost* or "Eye Consolation," to gratify his blind friend Lucretia van Trollo. He made his solitary effort in the dramatic line in 1657, when he brought out his comedy of *Trijntje Cornelis Klacht*, which deals, in rather broad humour, with the adventures of the wife of a ship's captain at Zaandam. In 1658 he rearranged his poems, and issued them with many additions, under the title of *Corn Flowers*. He proposed to the government that the present highway from the Hague to the sea at Scheveningen should be constructed, and during his absence on a diplomatic mission to the French court in 1666 the road was made as a compliment to the venerable statesman, who expressed his gratitude in a descriptive poem entitled *Zeestraet*. Huygens edited his poems for the last time in 1672, and died in his ninety-first year, on the 28th of March 1687. He was buried, with the pomp of a national funeral, in the church of St Jacob, on the 4th of April. His second son, Christiaan, the eminent astronomer, is noticed separately.

Constantijn Huygens is the most brilliant figure in Dutch literary history. Other statesmen surpassed him in political influence, and at least two other poets surpassed him in the value and originality of their writings. But his figure was more dignified and splendid, his talents were more varied, and his general accomplishments more remarkable than those of any other person of his age, the greatest age in the history of the Netherlands. Huygens is the *grand seigneur* of the republic, the type of aristocratic oligarchy, the jewel and ornament of Dutch liberty. When we consider his imposing character and the positive value of his writings, we may well be surprised that he has not found a modern editor. It is a disgrace to Dutch scholarship that no complete collection of the writings of Huygens exists. His autobiography, *De vita propria sermonum libri duo*, did not see the light until 1817, and his remarkable poem, *Cluyswerck*, was not printed until 1841. As a poet Huygens shows a finer sense of form than any other early Dutch writer; the language, in his hands, becomes as flexible as Italian. His epistles and lighter pieces, in particular, display his metrical ease and facility to perfection. (E. G.)

HUYSMANS, the name of four Flemish painters who matriculated in the Antwerp gild in the 17th century. Cornelis the elder, apprenticed in 1633, passed for a mastership in 1636, and remained obscure. Jacob, apprenticed to Frans Wouters in 1650, wandered to England towards the close of the reign of Charles II., and competed with Lely as a fashionable portrait painter. He executed a portrait of the queen, Catherine of Braganza, now in the national portrait gallery, and Horace Walpole assigns to him the likeness of Lady Bellasys, catalogued at Hampton Court as a work of Lely. His portrait of Izaak Walton in the National Gallery shows a disposition to imitate the styles of Rubens and Van Dyke. According to most accounts he died in London in 1696. Jan Baptist Huysmans, born at Antwerp in 1654, matriculated in 1676–1677, and died there in 1715–1716. He was younger brother to Cornelis Huysmans the second, who was born at Antwerp in 1648, and educated by Gaspar de Wit and Jacob van Artois. Of Jan Baptist little or nothing has been preserved, except that he registered numerous apprentices at Antwerp, and painted a landscape dated 1697 now in the Brussels museum. Cornelis the second is the only master of the name of Huysmans whose talent was largely acknowledged. He received lessons from two artists, one of whom was familiar with the Roman art of the Poussins, whilst the other inherited the scenic style of the school of Rubens. He combined the two in a rich, highly coloured, and usually effective style, which, however, was not free from monotony.

Seldom attempting anything but woodside views with fancy backgrounds, half Italian, half Flemish, he painted with great facility, and left numerous examples behind. At the outset of his career he practised at Malines, where he married in 1682, and there too he entered into some business connexion with van der Meulen, for whom he painted some backgrounds. In 1706 he withdrew to Antwerp, where he resided till 1717, returning then to Malines, where he died on the 1st of June 1727.

Though most of his pictures were composed for cabinets rather than churches, he sometimes emulated van Artois in the production of large sacred pieces, and for many years his "Christ on the Road to Emmaus" adorned the choir of Notre Dame of Malines. In the gallery of Nantes, where three of his small landscapes are preserved, there hangs an "Investment of Luxembourg," by van der Meulen, of which he is known to have laid in the background. The national galleries of London and Edinburgh contain each one example of his skill. Blenheim, too, and other private galleries in England, possess one or more of his pictures. But most of his works are on the European continent.

HUYSMANS, JORIS KARL (1848–1907), French novelist, was born at Paris on the 5th of February 1848. He belonged to a family of artists of Dutch extraction; he entered the ministry of the interior, and was pensioned after thirty years' service. His earliest venture in literature, *Le Drageoir à épices* (1874), contained stories and short prose poems showing the influence of Baudelaire. *Marthe* (1876), the life of a courtesan, was published in Brussels, and Huysmans contributed a story, "Sac au dos," to *Les Soirées de Médan*, the collection of stories of the Franco-German war published by Zola. He then produced a series of novels of everyday life, including *Les Sœurs Vatard* (1879), *En Ménage* (1881), and *À vau-l'eau* (1882), in which he outdid Zola in minute and uncompromising realism. He was influenced, however, more directly by Flaubert and the brothers de Goncourt than by Zola. In *L'Art moderne* (1883) he gave a careful study of impressionism and in *Certains* (1889) a series of studies of contemporary artists. *À Rebours* (1884), the history of the morbid tastes of a decadent aristocrat, des Esseintes, created a literary sensation, its caricature of literary and artistic symbolism covering much of the real beliefs of the leaders of the aesthetic revolt. In *Là-Bas* Huysmans's most characteristic hero, Durtal, makes his appearance. Durtal is occupied in writing the life of Gilles de Rais; the insight he gains into Satanism is supplemented by modern Parisian students of the black art; but already there are signs of a leaning to religion in the sympathetic figures of the religious bell-ringer of Saint Sulpice and his wife. *En Route* (1895) relates the strange conversion of Durtal to mysticism and catholicism in his retreat to La Trappe. In *La Cathédrale* (1898), Huysmans's symbolistic interpretation of the cathedral of Chartres, he develops his enthusiasm for the purity of Catholic ritual. The life of *Sainte Lydwine de Schiedam* (1901), an exposition of the value of suffering, gives further proof of his conversion; and *L'Oblat* (1903) describes Durtal's retreat to the Val des Saints, where he is attached as an oblate to a Benedictine monastery. Huysmans was nominated by Edmond de Goncourt as a member of the Académie des Goncourt. He died as a devout Catholic, after a long illness of cancer in the palate on the 13th of May 1907. Before his death he destroyed his unpublished MSS. His last book was *Les Foules de Lourdes* (1906).

See Arthur Symons, *Studies in two Literatures* (1897) and *The Symbolist Movement in Literature* (1899); Jean Lionnet in *L'Évolution des idées* (1903); Eugène Gilbert in *France et Belgique* (1905); J. Sargeret in *Les Grands convertis* (1906).

HUYSUM, JAN VAN (1682–1749), Dutch painter, was born at Amsterdam in 1682, and died in his native city on the 8th of February 1749. He was the son of Justus van Huysum, who is said to have been expeditious in decorating doorways, screens and vases. A picture by this artist is preserved in the gallery of Brunswick, representing Orpheus and the Beasts in a wooded landscape, and here we have some explanation of his son's fondness for landscapes of a conventional and Arcadian kind; for Jan van Huysum, though skilled as a painter of still life, believed himself to possess the genius of a landscape painter. Half his pictures in public galleries are landscapes, views of imaginary lakes and harbours with impossible ruins and classic edifices, and woods of tall and motionless trees—the whole very glossy and smooth, and entirely lifeless. The earliest dated work of this kind is that of 1717, in the Louvre, a grove with maidens culling flowers near a tomb, ruins of a portico, and a distant palace on the shores of a lake bounded by mountains.

It is doubtful whether any artist ever surpassed van Huysum in representing fruit and flowers. It has been said that his fruit has no savour and his flowers have no perfume—in other words, that they are hard and artificial—but this is scarcely true. In substance fruit and flower are delicate and finished imitations of nature in its more subtle varieties of matter. The fruit has an incomparable blush of down, the flowers have a perfect delicacy of tissue. Van Huysum, too, shows supreme art in relieving flowers of various colours against each other, and often against a light and transparent background. He is always bright, sometimes even gaudy. Great taste and much grace and elegance are apparent in the arrangement of bouquets and fruit in vases adorned with bas reliefs or in baskets on marble tables. There is exquisite and faultless finish everywhere. But what van Huysum has not is the breadth, the bold effectiveness, and the depth of thought of de Heem, from whom he descends through Abraham Mignon.

Some of the finest of van Huysum's fruit and flower pieces have been in English private collections: those of 1723 in the earl of Ellesmere's gallery, others of 1730–1732 in the collections of Hope and Ashburton. One of the best examples is now in the National Gallery (1736–1737). No public museum has finer and more numerous specimens than the Louvre, which boasts of four landscapes and six panels with still life; then come Berlin and Amsterdam with four fruit and flower pieces; then St Petersburg, Munich, Hanover, Dresden, the Hague, Brunswick, Vienna, Carlsruhe and Copenhagen.

HWANG HO [HOANG HO], the second largest river in China. It is known to foreigners as the Yellow river—a name which is a literal translation of the Chinese. It rises among the Kuen-lun mountains in central Asia, its head-waters being in close proximity to those of the Yangtsze-Kiang. It has a total length of about 2400 m. and drains an area of approximately 400,000 sq. m. The main stream has its source in two lakes named Tsaring-nor and Oring-nor, lying about 35° N., 97° E., and after flowing with a south-easterly course it bends sharply to the north-west and north, entering China in the province of Kansuh in lat. 36°. After passing Lanchow-fu, the capital of this province, the river takes an immense sweep to the north and north-east, until it encounters the rugged barrier ranges that here run north and south through the provinces of Shansi and Chihli. By these ranges it is forced due south for 500 m., forming the boundary between the provinces of Shansi and Shensi, until it finds an outlet eastwards at Tung Kwan—a pass which for centuries has been renowned as the gate of Asia, being indeed the sole commercial passage between central China and the West. At Tung Kwan the river is joined by its only considerable affluent in China proper, the Wei (Wei-ho), which drains the large province of Shensi, and the combined volume of water continues its way at first east and then north-east across the great plain to the sea. At low water in the winter season the discharge is only about 36,000 cub. ft. per second, whereas during the summer flood it reaches 116,000 ft. or more. The amount of sediment carried down is very large, though no accurate observations have been made. In the account of Lord Macartney's embassy, which crossed the Yellow river in 1792, it was calculated to be 17,520 million cub. ft. a year, but this is considered very much over the mark. Two reasons, however, combine to render it probable that the sedimentary matter is very large in proportion to the volume of water: the first being the great fall, and the consequently rapid current over two-thirds of the river's course; the second that the drainage area is nearly all covered with deposits of loess, which, being very friable, readily gives way before the rainfall and is washed down in large quantity. The ubiquity of this loess or yellow earth, as the Chinese call it, has in fact given its name both to the river which carries it in solution and to the sea (the Yellow Sea) into which it is discharged. It is calculated by Dr Guppy (*Journal of China Branch of Royal Asiatic Society*, vol. xvi.) that the sediment brought down by the three northern rivers of China, viz., the Yangtsze, the Hwang-ho and the Peiho, is 24,000 million cub. ft. per annum, and is sufficient to fill up the whole of the Yellow Sea and the Gulf of Pechili in the space of about 36,000 years.

Unlike the Yangtsze, the Hwang-ho is of no practical value for navigation. The silt and sand form banks and bars at the mouth, the water is too shallow in winter and the current is too strong in summer, and, further, the bed of the river is continually shifting. It is this last feature which has earned for the river the name "China's sorrow." As the silt-laden waters debouch from the rocky bed of the upper reaches on to the plains, the current slackens, and the coarser detritus settles on the bottom. By degrees the bed rises, and the people build embankments to prevent the river from overflowing. As the bed rises the embankments must be raised too, until the stream is flowing many feet above the level of the surrounding country. As time goes on the situation becomes more and more dangerous; finally, a breach occurs, and the whole river pours over the country, carrying destruction and ruin with it. If the breach cannot be repaired the river leaves its old channel entirely, and finds a new exit to the sea along the line of least resistance. Such in brief has been the story of the river since the dawn of Chinese history. At various times it has discharged its waters alternately on one side or the other of the great mass of mountains forming the promontory of Shantung, and by mouths as far apart from each other as 500 m. At each change it has worked havoc and disaster by covering the cultivated fields with 2 or 3 ft. of sand and mud.

A great change in the river's course occurred in 1851, when a breach was made in the north embankment near Kaifengfu in Honan. At this point the river bed was some 25 ft. above the plain; the water consequently forsook the old channel entirely and poured over the level country, finally seizing on the bed of a small river called the Tsing, and thereby finding an exit to the sea. Since that time the new channel thus carved out has remained the proper course of the river, the old or southerly channel being left quite dry. It required some fifteen or more years to repair damages from this outbreak, and to confine the stream by new embankments. After that there was for a time comparative immunity from inundations, but in 1882 fresh outbursts again began. The most serious of all took place in 1887, when it appeared probable that there would be again a permanent change in the river's course. By dint of great exertions, however, the government succeeded in closing the breach, though not till January 1889, and not until there had been immense destruction of life and property. The outbreak on this occasion occurred, as all the more serious outbreaks have done, in Honan, a few miles west of the city of Kaifengfu. The stream poured itself over the level and fertile country to the southwards, sweeping whole villages before it, and converting the plain into one vast lake. The area affected was not less than 50,000 sq. m. and the loss of life was computed at over one million. Since 1887 there have been a series of smaller outbreaks, mostly at points lower down and in the neighbourhood of Chinanfu, the capital of Shantung. These perpetually occurring disasters entail a heavy expense on the government; and from the mere pecuniary point of view it would well repay them to call in the best foreign engineering skill available, an expedient, however, which has not commended itself to the Chinese authorities. (G. J.)

HWICCE, one of the kingdoms of Anglo-Saxon Britain. Its exact dimensions are unknown; they probably coincided with those of the old diocese of Worcester, the early bishops of which bore the title "Episcopus Hwicciorum." It would therefore include Worcestershire, Gloucestershire except the Forest of Dean, the southern half of Warwickshire, and the neighbourhood of Bath. The name Hwicce survives in Wychwood in Oxfordshire and Whichford in Warwickshire. These districts, or at all events the southern portion of them, were according to the *Anglo-Saxon Chronicle, s.a.* 577, originally conquered by the West Saxons under Ceawlin. In later times, however, the kingdom of the Hwicce appears to have been always subject to Mercian supremacy, and possibly it was separated from Wessex in the time of Edwin. The first kings of whom we read were two brothers, Eanhere and Eanfrith, probably contemporaries of Wulfhere. They were followed by a king named Osric, a contemporary of Æthelred, and he by a king Oshere. Oshere had three sons who reigned after him, Æthelheard, Æthelweard and Æthelric. The two last named appear to have been reigning in the year 706. At the beginning of Offa's reign we again find the kingdom ruled by three brothers, named Eanberht, Uhtred and Aldred, the two latter of whom lived until about 780. After them the title of king seems to have been given up. Their successor Æthelmund, who was killed in a campaign against Wessex in 802, is described only as an earl. The district remained in possession of the rulers of Mercia until the fall of that kingdom. Together with the rest of English Mercia it submitted to King Alfred about 877–883 under Earl Æthelred, who possibly himself belonged to the Hwicce. No genealogy or list of kings has been preserved, and we do not know whether the dynasty was connected with that of Wessex or Mercia.

See Bede, *Historia eccles.* (edited by C. Plummer) iv. 13 (Oxford, 1896); W. de G. Birch, *Cartularium Saxonicum*, 43, 51, 76, 85, 116, 117, 122, 163, 187, 232, 233, 238 (Oxford, 1885–1889). (F. G. M. B.)

HYACINTH (Gr. ὑάκινθος), also called JACINTH (through Ital. *giacinto*), one of the most popular of spring garden flowers. It was in cultivation prior to 1597, at which date it is mentioned by Gerard. Rea in 1665 mentions several single and double varieties as being then in English gardens, and Justice in 1754 describes upwards of fifty single-flowered varieties, and nearly one hundred double-flowered ones, as a selection of the best from the catalogues of two then celebrated Dutch growers. One of the Dutch sorts, called La Reine de Femmes, a single white, is said to have produced from thirty-four to thirty-eight flowers in a spike, and on its first appearance to have sold for 50 guilders a bulb; while one called Overwinnaar, or Conqueror, a double blue, sold at first for 100 guilders, Gloria Mundi for 500 guilders, and Koning Saloman for 600 guilders. Several sorts are at that date mentioned as blooming well in water-glasses. Justice relates that he himself raised several very valuable double-flowered kinds from seeds, which many of the sorts he describes are noted for producing freely.

The original of the cultivated hyacinth, *Hyacinthus orientalis*, a native of Greece and Asia Minor, is by comparison an insignificant plant, bearing on a spike only a few small, narrow-lobed, washy blue flowers, resembling in form those of our common bluebell. So great has been the improvement effected by the florists, and chiefly by the Dutch, that the modern hyacinth would scarcely be recognized as the descendant of the type above referred to, the spikes being long and dense, composed of a large number of flowers; the spikes produced by strong bulbs not unfrequently measure 6 to 9 in. in length and from 7 to 9 in. in circumference, with the flowers closely set on from bottom to top. Of late years much improvement has been effected in the size of the individual flowers and the breadth of their recurving lobes, as well as in securing increased brilliancy and depth of colour.

The peculiarities of the soil and climate of Holland are so very favourable to their production that Dutch florists have made a specialty of the growth of those and other bulbous-rooted flowers. Hundreds of acres are devoted to the growth of hyacinths in the vicinity of Haarlem, and bring in a revenue of several hundreds of thousands of pounds. Some notion of the vast number imported into England annually may be formed from the fact that, for the supply of flowering plants to Covent Garden, one market grower alone produces from 60,000 to 70,000 in pots under glass, their blooming period being accelerated by artificial heat, and extending from Christmas onwards until they bloom naturally in the open ground.

In the spring flower garden few plants make a more effective display than the hyacinth. Dotted in clumps in the flower borders, and arranged in masses of well-contrasted colours in beds in the flower garden, there are no flowers which impart during their season—March and April—a gayer tone to the parterre. The bulbs are rarely grown a second time, either for indoor or outdoor culture, though with care they might be utilized for the latter purpose; and hence the enormous numbers which are procured each recurring year from Holland.

The first hyacinths were single-flowered, but towards the close of the 17th century double-flowered ones began to appear, and till a recent period these bulbs were the most esteemed. At the present time, however, the single-flowered sorts are in the ascendant, as they produce more regular and symmetrical spikes of blossom, the flowers being closely set and more or less horizontal in direction, while most of the double sorts have the bells distant and dependent, so that the spike is loose and by comparison ineffective. For pot culture, and for growth in water-glasses especially, the single-flowered sorts are greatly to be preferred. Few if any of the original kinds are now in cultivation, a succession of new and improved varieties having been raised, the demand for which is regulated in some respects by fashion.

The hyacinth delights in a rich light sandy soil. The Dutch incorporate freely with their naturally light soil a compost consisting of one-third coarse sea or river sand, one-third rotten cow dung without litter and one-third leaf-mould. The soil thus renovated retains its qualities for six or seven years, but hyacinths are not planted upon the same place for two years successively, intermediary crops of narcissus, crocus or tulips being taken. A good compost for hyacinths is sandy loam, decayed leaf-mould, rotten cow dung and sharp sand in equal parts, the whole being collected and laid up in a heap and turned over occasionally. Well-drained beds made up of this soil, and refreshed with a portion of new compost annually, would grow the hyacinth to perfection. The best time to plant the bulbs is towards the end of September and during October; they should be arranged in rows, 6 to 8 in. asunder, there being four rows in each bed. The bulbs should be sunk about 4 to 6 in. deep, with a small quantity of clean sand placed below and around each of them. The beds should be covered with decayed tan-bark, coco-nut fibre or half-rotten dung litter. As the flower-stems appear, they are tied to rigid but slender stakes to preserve them from accident. If the bulbs are at all prized, the stems should be broken off as soon as the flowering is over, so as not to exhaust the bulbs; the leaves, however, must be allowed to grow on till matured, but as soon as they assume a yellow colour, the bulbs are taken up, the leaves cut off near their base, and the bulbs laid out in a dry, airy, shady place to ripen, after which they are cleaned of loose earth and skin, ready for storing. It is the practice in Holland, about a month after the bloom, or when the tips of the leaves assume a withered appearance, to take up the bulbs, and to lay them sideways on the ground, covering them with an inch or two of earth. About three weeks later they are again taken up and cleaned. In the store-room they should be kept dry, well-aired and apart from each other.

Few plants are better adapted than the hyacinth for pot culture as greenhouse decorative plants; and by the aid of forcing they may be had in bloom as early as Christmas. They flower fairly well in 5-in. pots, the stronger bulbs in 6-in. pots. To bloom at Christmas, they should be potted early in September, in a compost resembling that already recommended for the open-air beds; and, to keep up a succession of bloom, others should be potted at intervals of a few weeks till the middle or end of November. The tops of the bulbs should be about level with the soil, and if a little sand is put immediately around them so much the better. The pots should be set in an open place on a dry hard bed of ashes, and be covered over to a depth of 6 or 8 in. with the same material or with fibre or soil; and when the roots are well developed, which will take from six to eight weeks, they may be removed to a frame, and gradually exposed to light, and then placed in a forcing pit in a heat of from 60° to 70°. When the flowers are fairly open, they may be removed to the greenhouse or conservatory.

The hyacinth may be very successfully grown in glasses for ornament in dwelling-houses. The glasses are filled to the neck with rain or even tap water, a few lumps of charcoal being dropped into them. The bulbs are placed in the hollow provided for them, so that their base just touches the water. This may be done in September or October. They are then set in a dark cupboard for a few weeks till roots are freely produced, and then gradually exposed to light. The early-flowering single white Roman hyacinth, a small-growing pure white variety, remarkable for its fragrance, is well adapted for forcing, as it can be had in bloom if required by November. For windows it grows well in the small glasses commonly used for crocuses; and for decorative purposes should be planted about five bulbs in a 5-in. pot, or in pans holding a dozen each. If grown for cut flowers it can be planted thickly in boxes of any convenient size. It is highly esteemed during the winter months by florists.

The Spanish hyacinth (*H. amethystinus*) and *H. azureus* are charming little bulbs for growing in masses in the rock garden or front of the flower border. The older botanists included in the genus *Hyacinthus* species of *Muscari*, *Scilla* and other genera of bulbous Liliaceae, and the name of hyacinth is still popularly applied to several other bulbous plants. Thus *Muscari botryoides* is the grape hyacinth, 6 in., blue or white, the handsomest; *M. moschatum*, the musk hyacinth, 10 in., has peculiar livid greenish-yellow flowers and a strong musky odour; *M. comosum* var. *monstrosum*, the feather hyacinth, bears sterile flowers broken up into a featherlike mass; *M. racemosum*, the starch hyacinth, is a native with deep blue plum-scented flowers. The Cape hyacinth is *Galtonia candicans*, a magnificent border plant, 3-4 ft. high, with large drooping white bell-shaped flowers; the star hyacinth, *Scilla amoena*; the Peruvian hyacinth or Cuban lily, *S. peruviana*, a native of the Mediterranean region, to which Linnaeus gave the species name *peruviana* on a mistaken assumption of its origin; the wild hyacinth or blue-bell, known variously as *Endymion nonscriptum*, *Hyacinthus nonscriptus* or *Scilla nutans*; the wild hyacinth of western North Amercia, *Camassia esculenta*. They all flourish in good garden soil of a gritty nature.

HYACINTH, or JACINTH, in mineralogy, a variety of zircon (*q.v.*) of yellowish red colour, used as a gem-stone. The *hyacinthus* of ancient writers must have been our sapphire, or blue corundum, while the hyacinth of modern mineralogists may have been the stone known as *lyncurium* (λυγκούριον). The Hebrew word *leshem*, translated ligure in the Authorized Version (Ex. xxviii. 19), from the λιγύριον of the Septuagint, appears in the Revised Version as jacinth, but with a marginal alternative of amber. Both jacinth and amber may be reddish yellow, but their identification is doubtful. As our jacinth (zircon) is not known in ancient Egyptian work, Professor Flinders Petrie has suggested that the *leshem* may have been a yellow quartz, or perhaps agate. Some old English writers describe the jacinth as yellow, whilst others refer to it as a blue stone, and the *hyacinthus* of some authorities seems undoubtedly to have been our sapphire. In Rev. xx. 20 the Revised Version retains the word jacinth, but gives sapphire as an alternative.

Most of the gems known in trade as hyacinth are only garnets—generally the deep orange-brown hessonite or cinnamon-stone—and many of the antique engraved stones reputed to be hyacinth are probably garnets. The difference may be detected optically, since the garnet is singly and the hyacinth doubly refracting; moreover the specific gravity affords a simple means of diagnosis, that of garnet being only about 3·7, whilst hyacinth may have a density as high as 4·7. Again, it was shown many years ago by Sir A. H. Church that most hyacinths, when examined by the spectroscope, show a series of dark absorption bands, due perhaps to the presence of some rare element such as uranium or erbium.

Hyacinth is not a common mineral. It occurs, with other zircons, in the gem-gravels of Ceylon, and very fine stones have been found as pebbles at Mudgee in New South Wales. Crystals of zircon, with all the typical characters of hyacinth, occur at Expailly, Le Puy-en-Velay, in Central France, but they are not large enough for cutting. The stones which have been called Compostella hyacinths are simply ferruginous quartz from Santiago de Compostella in Spain. (F. W. R.*)

HYACINTHUS,[1] in Greek mythology, the youngest son of the Spartan king Amyclas, who reigned at Amyclae (so Pausanias iii. 1. 3, iii. 19. 5; and Apollodorus i. 3. 3, iii. 10. 3). Other stories make him son of Oebalus, of Eurotas, or of Pierus and the nymph Clio (see Hyginus, *Fabulae*, 271; Lucian, *De saltatione*, 45, and *Dial. deor.* 14). According to the general story, which is probably late and composite, his great beauty attracted the love of Apollo, who killed him accidentally when teaching him to throw the *discus* (quoit); others say that Zephyrus (or Boreas) out of jealousy deflected the quoit so that it hit Hyacinthus on the head and killed him. According to the representation on the tomb at Amyclae (Pausanias, *loc. cit.*) Hyacinthus was translated into heaven with his virgin sister Polyboea. Out of his blood there grew the flower known as the hyacinth, the petals of which were marked with the mournful exclamation AI, AI, "alas" (cf. "that sanguine flower inscribed with woe"). This Greek hyacinth cannot have been the flower which now bears the name; it has been identified with a species of iris and with the larkspur (*delphinium Aiacis*), which appear to have the markings described. The Greek hyacinth was also said to have sprung from the blood of Ajax. Evidently the Greek authorities confused both the flowers and the traditions.

The death of Hyacinthus was celebrated at Amyclae by the second most important of Spartan festivals, the Hyacinthia, which took place in the Spartan month Hecatombeus. What month this was is not certain. Arguing from Xenophon (*Hell.* iv. 5) we get May; assuming that the Spartan Hecatombeus is the Attic Hecatombaion, we get July; or again it may be the Attic Scirophorion, June. At all events the Hyacinthia was an early summer festival. It lasted three days, and the rites gradually passed from mourning for Hyacinthus to rejoicings

[1] The word is probably derived from an Indo-European root, meaning "youthful," found in Latin, Greek, English and Sanskrit. Some have suggested that the first two letters are from ὕειν, to rain, (cf. Hyades).

in the majesty of Apollo, the god of light and warmth, and giver of the ripe fruits of the earth (see a passage from Polycrates, *Laconica*, quoted by Athenaeus 139 D; criticized by L. R. Farnell, *Cults of the Greek States*, iv. 266 foll.). This festival is clearly connected with vegetation, and marks the passage from the youthful verdure of spring to the dry heat of summer and the ripening of the corn.

The precise relation which Apollo bears to Hyacinthus is obscure. The fact that at Tarentum a Hyacinthus tomb is ascribed by Polybius to Apollo Hyacinthus (not Hyacinthius) has led some to think that the personalities are one, and that the hero is merely an emanation from the god; confirmation is sought in the Apolline appellation τετράχειρ, alleged by Hesychius to have been used in Laconia, and assumed to describe a composite figure of Apollo-Hyacinthus. Against this theory is the essential difference between the two figures. Hyacinthus is a chthonian vegetation god whose worshippers are afflicted and sorrowful; Apollo, though interested in vegetation, is never regarded as inhabiting the lower world, his death is not celebrated in any ritual, his worship is joyous and triumphant, and finally the Amyclean Apollo is specifically the god of war and sông. Moreover, Pausanias describes the monument at Amyclae as consisting of a rude figure of Apollo standing on an altar-shaped base which formed the tomb of Hyacinthus. Into the latter offerings were put for the hero before gifts were made to the god.

On the whole it is probable that Hyacinthus belongs originally to the pre-Dorian period, and that his story was appropriated and woven into their own Apollo myth by the conquering Dorians. Possibly he may be the apotheosis of a pre-Dorian king of Amyclae. J. G. Frazer further suggests that he may have been regarded as spending the winter months in the underworld and returning to earth in the spring when the " hyacinth " blooms. In this case his festival represents perhaps both the Dorian conquest of Amyclae and the death of spring before the ardent heat of the summer sun, typified as usual by the *discus* (quoit) with which Apollo is said to have slain him. With the growth of the hyacinth from his blood should be compared the oriental stories of violets springing from the blood of Attis, and roses and anemones from that of Adonis. As a youthful vegetation god, Hyacinthus may be compared with Linus and Scephrus, both of whom are connected with Apollo Agyieus.

Rhode, *Psyche*, 3rd ed. i. 137 foll.; Roscher, *Lexikon d. griech. u. röm. Myth.*, s.v. " Hyakinthos " (Greve); L. Preller, *Griechische Mythol.* 4th ed. i. 248 foll. (J. M. M.)

HYADES (" the rainy ones "), in Greek mythology, the daughters of Atlas and Aethra; their number varies between two and seven. As a reward for having brought up Zeus at Dodona and taken care of the infant Dionysus Hyes, whom they conveyed to Ino (sister of his mother Semele) at Thebes when his life was threatened by Lycurgus, they were translated to heaven and placed among the stars (Hyginus, *Poët. astron.* ii. 21). Another form of the story combines them with the Pleiades. According to this they were twelve (or fifteen) sisters, whose brother Hyas was killed by a snake while hunting in Libya (Ovid, *Fasti*, v. 165; Hyginus, *Fab.* 192). They lamented him so bitterly that Zeus, out of compassion, changed them into stars—five into the Hyades, at the head of the constellation of the Bull, the remainder into the Pleiades. Their name is derived from the fact that the rainy season commenced when they rose at the same time as the sun (May 7–21); the original conception of them is that of the fertilizing principle of moisture. The Romans derived the name from ὗς (pig), and translated it by *Suculae* (Cicero, *De nat. deorum*, ii. 43).

HYATT, ALPHEUS (1838–1902), American naturalist, was born at Washington, D.C., on the 5th of April 1838. From 1858 to 1862 he studied at Harvard, where he had Louis Agassiz for his master, and in 1863 he served as a volunteer in the Civil War, attaining the rank of captain. In 1867 he was appointed curator of the Essex Institute at Salem, and in 1870 became professor of zoology and palaeontology at the Massachusetts Institute of Technology (resigned 1888), and custodian of the Boston Society of Natural History (curator in 1881). In 1886 he was appointed assistant for palaeontology in the Cambridge museum of comparative anatomy, and in 1889 was attached to the United States Geological Survey as palaeontologist for the Trias and Jura. He was the chief founder of the American Society of Naturalists, of which he acted as first president in 1883, and he also took a leading part in establishing the marine biological laboratories at Annisquam and Woods Hole, Mass. He died at Cambridge on the 15th of January 1902.

His works include *Observations on Fresh-water Polyzoa* (1866); *Fossil Cephalopods of the Museum of Comparative Zoology* (1872); *Revision of North American Porifera* (1875–1877); *Genera of Fossil Cephalopoda* (1883); *Larval Theory of the Origin of Cellular Tissue* (1884); *Genesis of the Arietidae* (1889); and *Phylogeny of an acquired characteristic* (1894). He wrote the section on Cephalopoda in Karl von Zittel's *Paläontologie* (1900), and his well-known study on the fossil pond snails of Steinheim (" The Genesis of the Tertiary Species of Planorbis at Steinheim ") appeared in the *Memoirs* of the Boston Natural History Society in 1880. He was one of the founders and editors of the *American Naturalist*.

HYBLA, the name of several cities in Sicily. The best known historically, though its exact site is uncertain, is Hybla Major, near (or by some supposed to be identical with) Megara Hyblaea (*q.v.*): another Hybla, known as Hybla Minor or Galeatis, is represented by the modern Paternò; while the site of Hybla Heraea is to be sought near Ragusa.

HYBRIDISM. The Latin word *hybrida, hibrida* or *ibrida* has been assumed to be derived from the Greek ὕβρις, an insult or outrage, and a hybrid or mongrel has been supposed to be an outrage on nature, an unnatural product. As a general rule animals and plants belonging to distinct species do not produce offspring when crossed with each other, and the term hybrid has been employed for the result of a fertile cross between individuals of different species, the word mongrel for the more common result of the crossing of distinct varieties. A closer scrutiny of the facts, however, makes the term hybridism less isolated and more vague. The words species and genus, and still more subspecies and variety, do not correspond with clearly marked and sharply defined zoological categories, and no exact line can be drawn between the various kinds of crossings from those between individuals apparently identical to those belonging to genera universally recognized as distinct. Hybridism therefore grades into mongrelism, mongrelism into cross-breeding, and cross-breeding into normal pairing, and we can say little more than that the success of the union is the more unlikely or more unnatural the further apart the parents are in natural affinity.

The interest in hybridism was for a long time chiefly of a practical nature, and was due to the fact that hybrids are often found to present characters somewhat different from those of either parent. The leading facts have been known in the case of the horse and ass from time immemorial. The earliest recorded observation of a hybrid plant is by J. G. Gmelin towards the end of the 17th century; the next is that of Thomas Fairchild, who in the second decade of the 18th century, produced the cross which is still grown in gardens under the name of " Fairchild's Sweet William." Linnaeus made many experiments in the cross-fertilization of plants and produced several hybrids, but Joseph Gottlieb Kölreuter (1733–1806) laid the first real foundation of our scientific knowledge of the subject. Later on Thomas Andrew Knight, a celebrated English horticulturist, devoted much successful labour to the improvement of fruit trees and vegetables by crossing. In the second quarter of the 19th century C. F. Gärtner made and published the results of a number of experiments that had not been equalled by any earlier worker. Next came Charles Darwin, who first in the *Origin of Species*, and later in *Cross and Self-Ferlilization of Plants*, subjected the whole question to a critical examination, reviewed the known facts and added many to them.

Darwin's conclusions were summed up by G. J. Romanes in the 9th edition of this *Encyclopaedia* as follows:—

1. The laws governing the production of hybrids are identical, or nearly identical, in the animal and vegetable kingdoms.

2. The sterility which so generally attends the crossing of two specific forms is to be distinguished as of two kinds, which, although

often confounded by naturalists, are in reality quite distinct. For the sterility may obtain between the two parent species when first crossed, or it may first assert itself in their hybrid progeny. In the latter case the hybrids, although possibly produced without any appearance of infertility on the part of their parent species, nevertheless prove more or less infertile among themselves, and also with members of either parent species.

3. The degree of both kinds of infertility varies in the case of different species, and in that of their hybrid progeny, from absolute sterility up to complete fertility. Thus, to take the case of plants, "when pollen from a plant of one family is placed on the stigma of a plant of a distinct family, it exerts no more influence than so much inorganic dust. From this absolute zero of fertility, the pollen of different species, applied to the stigma of some one species of the same genus, yields a perfect gradation in the number of seeds produced, up to nearly complete, or even quite complete, fertility; so, in hybrids themselves, there are some which never have produced, and probably never would produce, even with the pollen of the pure parents, a single fertile seed; but in some of these cases a first trace of fertility may be detected, by the pollen of one of the pure parent species causing the flower of the hybrid to wither earlier than it otherwise would have done; and the early withering of the flower is well known to be a sign of incipient fertilization. From this extreme degree of sterility we have self-fertilized hybrids producing a greater and greater number of seeds up to perfect fertility."

4. Although there is, as a rule, a certain parallelism, there is no fixed relation between the degree of sterility manifested by the parent species when crossed and that which is manifested by their hybrid progeny. There are many cases in which two pure species can be crossed with unusual facility, while the resulting hybrids are remarkably sterile; and, contrariwise, there are species which can only be crossed with extreme difficulty, though the hybrids, when produced, are very fertile. Even within the limits of the same genus, these two opposite cases may occur.

5. When two species are reciprocally crossed, *i.e.* male A with female B, and male B with female A, the degree of sterility often differs greatly in the two cases. The sterility of the resulting hybrids may differ likewise.

6. The degree of sterility of first crosses and of hybrids runs, to a certain extent, parallel with the systematic affinity of the forms which are united. "For species belonging to distinct genera can rarely, and those belonging to distinct families can never, be crossed. The parallelism, however, is far from complete; for a multitude of closely allied species will not unite, or unite with extreme difficulty, whilst other species, widely different from each other, can be crossed with perfect facility. Nor does the difficulty depend on ordinary constitutional differences; for annual and perennial plants, deciduous and evergreen trees, plants flowering at different seasons, inhabiting different stations, and naturally living under the most opposite climates, can often be crossed with ease. The difficulty or facility apparently depends exclusively on the sexual constitution of the species which are crossed, or on their sexual elective affinity."

There are many new records as to the production of hybrids. Horticulturists have been extremely active and successful in their attempts to produce new flowers or new varieties of vegetables by seminal or graft-hybrids, and any florist's catalogue or the account of any special plant, such as is to be found in Foster-Melliar's *Book of the Rose*, is in great part a history of successful hybridization. Much special experimental work has been done by botanists, notably by de Vries, to the results of whose experiments we shall recur. Experiments show clearly that the obtaining of hybrids is in many cases merely a matter of taking sufficient trouble, and the successful crossing of genera is not infrequent.

Focke, for instance, cites cases where hybrids were obtained between *Brassica* and *Raphanus*, *Galium* and *Asperula*, *Campanula* and *Phyteuma*, *Verbascum* and *Celsia*. Among animals, new records and new experiments are almost equally numerous. Boveri has crossed *Echinus microtuberculatus* with *Sphaerechinus granularis*. Thomas Hunt Morgan even obtained hybrids between *Asterias*, a starfish, and *Arbacia*, a sea-urchin, a cross as remote as would be that between a fish and a mammal. Vernon got many hybrids by fertilizing the eggs of *Strongylocentrotus lividus* with the sperm of *Sphaerechinus granularis*. Standfuss has carried on an enormous series of experiments with Lepidopterous insects, and has obtained a very large series of hybrids, of which he has kept careful record. Lepidopterists generally begin to suspect that many curious forms offered by dealers as new species are products got by crossing known species. Apellö has succeeded with Teleostean fish; Gebhardt and others with Amphibia. Elliot and Suchetet have studied carefully the question of hybridization occurring normally among birds, and have got together a very large body of evidence. Among the cases cited by Elliot the most striking are that of the hybrid between *Colaptes cafer* and *C. auratus*, which occurs over a very wide area of North America and is known as *C. hybridus*, and the hybrid between *Euplocamus lineatus* and *E. horsfieldi*, which appears to be common in Assam. St M. Podmore has produced successful crosses between the wood-pigeon (*Columba palumbus*) and a domesticated variety of the rock pigeon (*C. livia*). Among mammals noteworthy results have been obtained by Professor Cossar Ewart, who has bred nine zebra hybrids by crossing mares of various sizes with a zebra stallion, and who has studied in addition three hybrids out of zebra mares, one sired by a donkey, the others by ponies. Crosses have been made between the common rabbit (*Lepus cuniculus*) and the guinea-pig (*Cavia cobaya*), and examples of the results have been exhibited in the Zoological Gardens of Sydney, New South Wales. The Carnivora generally are very easy to hybridize, and many successful experiments have been made with animals in captivity. Karl Hagenbeck of Hamburg has produced crosses between the lion (*Felis leo*) and the tiger (*F. tigris*). What was probably a "tri-hybrid" in which lion, leopard and jaguar were mingled was exhibited by a London showman in 1908. Crosses between various species of the smaller cats have been fertile on many occasions. The black bear (*Ursus americanus*) and the European brown bear (*U. arctos*) bred in the London Zoological Gardens in 1859, but the three cubs did not reach maturity. Hybrids between the brown bear and the grizzly-bear (*U. horribilis*) have been produced in Cologne, whilst at Halle since 1874 a series of successful matings of polar (*U. maritimus*) and brown bears have been made. Examples of these hybrid bears have been exhibited by the London Zoological Society. The London Zoological Society has also successfully mated several species of antelopes, for instance, the water-bucks *Kobus ellipsiprymnus* and *K. unctuosus*, and Selous's antelope *Limnotragus selousi* with *L. gratus*.

The causes militating against the production of hybrids have also received considerable attention. Delage, discussing the question, states that there is a general proportion between sexual attraction and zoological affinity, and in many cases hybrids are not naturally produced simply from absence of the stimulus to sexual mating, or because of preferential mating within the species or variety. In addition to differences of habit, temperament, time of maturity, and so forth, gross structural differences may make mating impossible. Thus Escherick contends that among insects the peculiar structure of the genital appendages makes cross-impregnation impossible, and there is reason to believe that the specific peculiarities of the modified sexual palps in male spiders have a similar result.

The difficulties, however, may not exist, or may be overcome by experiment, and frequently it is only careful management that is required to produce crossing. Thus it has been found that when the pollen of one species does not succeed in fertilizing the ovules of another species, yet the reciprocal cross may be successful; that is to say, the pollen of the second species may fertilize the ovules of the first. H. M. Vernon, working with sea-urchins, found that the obtaining of hybrids depended on the relative maturity of the sexual products. The difficulties in crossing apparently may extend to the chemiotaxic processes of the actual sexual cells. Thus when the spermatozoa of an urchin were placed in a drop of sea-water containing ripe eggs of an urchin and of a starfish, the former eggs became surrounded by clusters of the male cells, while the latter appeared to exert little attraction for the alien germ-cells. Finally, when the actual impregnation of the egg is possible naturally, or has been secured by artificial means, the development of the hybrid may stop at an early stage. Thus hybrids between the urchin and the starfish, animals belonging to different classes, reached only the stage of the pluteus larva. A. D. Apellö, experimenting with Teleostean fish, found that very often impregnation and segmentation occurred, but that the development broke down immediately afterwards. W. Gebhardt, crossing *Rana esculenta* with *R. arvalis*, found that the cleavage of the ovum was normal, but that abnormality began with the gastrula, and that development soon stopped. In a very general fashion there appears to be a parallel between the zoological affinity and the extent to which the incomplete development of the hybrid proceeds.

As to the sterility of hybrids *inter se*, or with either of the parent forms, information is still wanted. Delage, summing up the evidence in a general way, states that mongrels are more fertile and stronger than their parents, while hybrids are at least equally hardy but less fertile. While many of the hybrid products of horticulturists are certainly infertile, others appear to be indefinitely fertile.

Focke, it is true, states that the hybrids between *Primula auricula* and *P. hirsuta* are fertile for many generations, but not indefinitely so; but, while this may be true for the particular case, there seems no reason to doubt that many plant hybrids are quite fertile. In the case of animals the evidence is rather against fertility. Standfuss, who has made experiments lasting over many years, and who has dealt with many genera of Lepidoptera, obtained no fertile hybrid females, although he found that hybrid males paired readily and successfully with pure-bred females of the parent races. Elliot, dealing with birds, concluded that no hybrids were fertile with one another beyond the second generation, but thought that they were fertile with members of the parent races. Wallace, on the other hand, cites from Quatrefages the case of hybrids between the moths *Bombyx cynthia* and *B. arrindia*, which were stated to be fertile *inter se* for eight generations. He also states that hybrids between the sheep and goat have a limited fertility *inter se*. Charles Darwin, however, had evidence that some hybrid pheasants were completely fertile, and he himself interbred the progeny of crosses between the common and Chinese geese, whilst there appears to be no doubt as to the complete fertility of the crosses between many species of ducks, J. L. Bonhote having interbred in various crosses for several generations the mallard (*Anas boschas*), the Indian spot-bill duck (*A. poecilorhyncha*), the New Zealand grey duck (*A. superciliosa*) and the pin-tail (*Dafila acuta*). Podmore's pigeon hybrids were fertile *inter se*, a specimen having been exhibited at the London Zoological Gardens. The hybrids between the brown and polar bears bred at Halle proved to be fertile, both with one of the parent species and with one another.

Cornevin and Lesbre state that in 1873 an Arab mule was fertilized in Africa by a stallion, and gave birth to female offspring which she suckled. All three were brought to the Jardin d'Acclimatation in Paris, and there the mule had a second female colt to the same father, and subsequently two male colts in succession to an ass and to a stallion. The female progeny were fertilized, but their offspring were feeble and died at birth. Cossar Ewart gives an account of a recent Indian case in which a female mule gave birth to a male colt. He points out, however, that many mistakes have been made about the breeding of hybrids, and is not altogether inclined to accept this supposed case. Very little has been published with regard to the most important question, as to the actual condition of the sexual organs and cells in hybrids. There does not appear to be gross anatomical defect to account for the infertility of hybrids, but microscopical examination in a large number of cases is wanted. Cossar Ewart, to whom indeed much of the most interesting recent work on hybrids is due, states that in male zebra-hybrids the sexual cells were immature, the tails of the spermatozoa being much shorter than those of the similar cells in stallions and zebras. He adds, however, that the male hybrids he examined were young, and might not have been sexually mature. He examined microscopically the ovary of a female zebra-hybrid and found one large and several small Graafian follicles, in all respects similar to those in a normal mare or female zebra. A careful study of the sexual organs in animal and plant hybrids is very much to be desired, but it may be said that so far as our present knowledge goes there is not to be expected any obvious microscopical cause of the relative infertility of hybrids.

The relative variability of hybrids has received considerable attention from many writers. Horticulturists, as Bateson has written, are "aware of the great and striking variations which occur in so many orders of plants when hybridization is effected." The phrase has been used "breaking the constitution of a plant" to indicate the effect produced in the offspring of a hybrid union, and the device is frequently used by those who are seeking for novelties to introduce on the market. It may be said generally that hybrids are variable, and that the products of hybrids are still more variable. J. L. Bonhote found extreme variations amongst his hybrid ducks. Y. Delage states that in reciprocal crosses there is always a marked tendency for the offspring to resemble the male parents; he quotes from Huxley that the mule, whose male parent is an ass, is more like the ass, and that the hinny, whose male parent is a horse, is more like the horse. Standfuss found among Lepidoptera that males were produced much more often than females, and that these males paired readily. The freshly hatched larvae closely resembled the larvae of the female parent, but in the course of growth the resemblance to the male increased, the extent of the final approximation to the male depending on the relative phylogenetic age of the two parents, the parent of the older species being prepotent. In reciprocal pairing, he found that the male was able to transmit the characters of the parents in a higher degree. Cossar Ewart, in relation to zebra hybrids, has discussed the matter of resemblance to parents in very great detail, and fuller information must be sought in his writings. He shows that the wild parent is not necessarily prepotent, although many writers have urged that view. He described three hybrids bred out of a zebra mare by different horses, and found in all cases that the resemblance to the male or horse parent was more profound. Similarly, zebra-donkey hybrids out of zebra mares bred in France and in Australia were in characters and disposition far more like the donkey parents. The results which he obtained in the hybrids which he bred from a zebra stallion and different mothers were more variable, but there was rather a balance in favour of zebra disposition and against zebra shape and marking.

"Of the nine zebra-horse hybrids I have bred," he says, "only two in their make and disposition take decidedly after the wild parent. As explained fully below, all the hybrids differ profoundly in the plan of their markings from the zebra, while in their ground colour they take after their respective dams or the ancestors of their dams far more than after the zebra—the hybrid out of the yellow and white Iceland pony, *e.g.* instead of being light in colour, as I anticipated, is for the most part of a dark dun colour, with but indistinct stripes. The hoofs, mane and tail of the hybrids are at the most intermediate, but this is perhaps partly owing to reversion towards the ancestors of these respective dams. In their disposition and habits they all undoubtedly agree more with the wild sire."

Ewart's experiments and his discussion of them also throw important light on the general relation of hybrids to their parents. He found that the coloration and pattern of his zebra hybrids resembled far more those of the Somali or Grévy's zebra than those of their sire—a Burchell's zebra. In a general discussion of the stripings of horses, asses and zebras, he came to the conclusion that the Somali zebra represented the older type, and that therefore his zebra hybrids furnished important evidence of the effect of crossing in producing reversion to ancestral type. The same subject has of course been discussed at length by Darwin, in relation to the cross-breeding of varieties of pigeons; but the modern experimentalists who are following the work of Mendel interpret reversion differently (see MENDELISM).

Graft-Hybridism.—It is well known that, when two varieties or allied species are grafted together, each retains its distinctive characters. But to this general, if not universal, rule there are on record several alleged exceptions, in which either the scion is said to have partaken of the qualities of the stock, the stock of the scion, or each to have affected the other. Supposing any of these influences to have been exerted, the resulting product would deserve to be called a graft-hybrid. It is clearly a matter of great interest to ascertain whether such formation of hybrids by grafting is really possible; for, if even one instance of such formation could be unequivocally proved, it would show that sexual and asexual reproduction are essentially identical.

The cases of alleged graft-hybridism are exceedingly few, considering the enormous number of grafts that are made every year by horticulturists, and have been so made for centuries. Of these cases the most celebrated are those of Adam's laburnum (*Cylisus Adami*) and the bizzarria orange. Adam's laburnum is now flourishing in numerous places throughout Europe, all the trees having been raised as cuttings from the original graft, which was made by inserting a bud of the purple laburnum into a stock of the yellow. M. Adam, who made the graft, has left on record that from it there sprang the existing hybrid. There can be no question as to the truly hybrid character of the latter—all the peculiarities of both parent species being often blended in the same raceme, flower or even petal; but until the experiment shall have been successfully repeated there must always remain a strong suspicion that, notwithstanding the assertion and doubtless the belief of M. Adam, the hybrid arose as a cross in the ordinary way of seminal reproduction. Similarly, the bizzarria orange, which is unquestionably a hybrid between the bitter orange and the citron—since it presents the remarkable spectacle of these two different fruits blended into one—is stated by the gardener who first succeeded in producing it to have arisen as a graft-hybrid; but here again a similar doubt, similarly due to the need of corroboration, attaches to the statement. And the same remark applies to the still more wonderful case of the so-called trifacial orange, which blends three distinct kinds of fruit in one, and which is said to have been produced by artificially splitting and uniting the seeds taken from the three distinct species, the fruits of which now occur blended in the triple hybrid.

The other instances of alleged graft-hybridism are too numerous to be here noticed in detail; they refer to jessamine, ash, hazel, vine, hyacinth, potato, beet and rose. Of these the cases of the vine, beet and rose are the strongest as evidence of graft-hybridization, from the fact that some of them were produced as the result of careful experiments made by very competent experimentalists. On the whole, the results of some of these experiments, although so few in number, must be regarded as making out a strong case in favour of the possibility of graft-hybridism. For it must always be remembered that, in experiments of this kind, negative evidence, however great in amount, may be logically dissipated by a single positive result.

Theory of Hybridism.—Charles Darwin was interested in hybridism as an experimental side of biology, but still more from the bearing of the facts on the theory of the origin of species. It is obvious that although hybridism is occasionally possible as an exception to the general infertility of species *inter se*, the exception is still more minimized when it is remembered that the hybrid progeny usually display some degree of sterility. The main facts of hybridism appear to lend support to the old doctrine that there are placed between all species the barriers of mutual sterility. The argument for the fixity of species appears still stronger when the general infertility of species crossing is contrasted with the general fertility of the crossing of natural and artificial varieties. Darwin himself, and afterwards G. J. Romanes, showed, however, that the theory of natural selection did not require the possibility of the commingling of specific types, and that there was no reason to suppose that the mutation of species should depend upon their mutual crossing. There existed more than enough evidence, and this has been added to since, to show that infertility with other species is no criterion of a species, and that there is no exact parallel between the degree of affinity between forms and their readiness to cross. The problem of hybridism is no more than the explanation of the generally reduced fertility of remoter crosses as compared with the generally increased fertility of crosses between organisms slightly different. Darwin considered and rejected the view that the inter-sterility of species could have been the result of natural selection.

"At one time it appeared to me probable," he wrote (*Origin of Species*, 6th ed. p. 247), "as it has to others, that the sterility of first crosses and of hybrids might have been slowly acquired through the natural selection of slightly lessened degrees of fertility, which, like any other variation, spontaneously appeared in certain individuals of one variety when crossed with those of another variety. For it would clearly be advantageous to two varieties or incipient species if they could be kept from blending, on the same principle that, when man is selecting at the same time two varieties, it is necessary that he should keep them separate. In the first place, it may be remarked that species inhabiting distinct regions are often sterile when crossed; now it could clearly have been of no advantage to such separated species to have been rendered mutually sterile and, consequently, this could not have been effected through natural selection; but it may perhaps be argued that, if a species were rendered sterile with some one compatriot, sterility with other species would follow as a necessary contingency. In the second place, it is almost as much opposed to the theory of natural selection as to that of special creation, that in reciprocal crosses the male element of one form should have been rendered utterly impotent on a second form, whilst at the same time the male element of this second form is enabled freely to fertilize the first form; for this peculiar state of the reproductive system could hardly have been advantageous to either species."

Darwin came to the conclusion that the sterility of crossed species must be due to some principle quite independent of natural selection. In his search for such a principle he brought together much evidence as to the instability of the reproductive system, pointing out in particular how frequently wild animals in captivity fail to breed, whereas some domesticated races have been so modified by confinement as to be fertile together although they are descended from species probably mutually infertile. He was disposed to regard the phenomena of differential sterility as, so to speak, by-products of the process of evolution. G. J. Romanes afterwards developed his theory of physiological selection, in which he supposed that the appearance of differential fertility within a species was the starting-point of new species; certain individuals by becoming fertile only *inter se* proceeded along lines of modification diverging from the lines followed by other members of the species. Physiological selection in fact would operate in the same fashion as geographical isolation; if a portion of a species separated on an island tends to become a new species, so also a portion separated by infertility with the others would tend to form a new species. According to Romanes, therefore, mutual infertility was the starting-point, not the result, of specific modification. Romanes, however, did not associate his interesting theory with a sufficient number of facts, and it has left little mark on the history of the subject. A. R. Wallace, on the other hand, has argued that sterility between incipient species may have been increased by natural selection in the same fashion as other favourable variations are supposed to have been accumulated. He thought that "some slight degree of infertility was a not infrequent accompaniment of the external differences which always arise in a state of nature between varieties and incipient species."

Weismann concluded, from an examination of a series of plant hybrids, that from the same cross hybrids of different character may be obtained, but that the characters are determined at the moment of fertilization; for he found that all the flowers on the same hybrid plant resembled one another in the minutest details of colour and pattern. Darwin already had pointed to the act of fertilization as the determining point, and it is in this direction that the theory of hybridism has made the greatest advance.

The starting-point of the modern views comes from the experiments and conclusions on plant hybrids made by Gregor Mendel and published in 1865. It is uncertain if Darwin had paid attention to this work; Romanes, writing in the 9th edition of this *Encyclopaedia*, cited it without comment. First H. de Vries, then W. Bateson and a series of observers returned to the work of Mendel (see MENDELISM), and made it the foundation of much experimental work and still more theory. It is still too soon to decide if the confident predictions of the Mendelians are justified, but it seems clear that a combination of Mendel's numerical results with Weismann's (see HEREDITY) conception of the particulate character of the germ-plasm, or hereditary material, is at the root of the phenomena of hybridism, and that Darwin was justified in supposing it to lie outside the sphere of natural selection and to be a fundamental fact of living matter.

HYDANTOIN (glycolyl urea), $C_3H_4N_2O_2$ or $CO\begin{matrix}\overset{\beta}{NH}\cdot\overset{\alpha}{CH_2} \\ NH\cdot\underset{\gamma}{CO}\end{matrix}$, the ureïde of glycollic acid, may be obtained by heating allantoin or alloxan with hydriodic acid, or by heating bromacetyl urea with alcoholic ammonia. It crystallizes in needles, melting at 216° C.

When hydrolysed with baryta water yields hydantoic (glycoluric) acid, $H_2N \cdot CO \cdot NH \cdot CH_2 \cdot CO_2H$, which is readily soluble in hot water, and on heating with hydriodic acid decomposes into ammonia, carbon dioxide and glycocoll, $CH_2 \cdot NH_2 \cdot CO_2 \cdot H$. Many substituted hydantoins are known; the α-alkyl hydantoins are formed on fusion of aldehyde- or ketone-cyanhydrins with urea, the β-alkyl hydantoins from the fusion of mono-alkyl glycocolls with urea, and the γ-alkyl hydantoins from the action of alkalis and alkyl iodides on the α-compounds. γ-Methyl hydantoin has been obtained as a splitting product of caffeine (E. Fischer, *Ann.*, 1882, 215, p. 253).

HYDE, the name of an English family distinguished in the 17th century. Robert Hyde of Norbury, Cheshire, had several sons, of whom the third was Lawrence Hyde of Gussage St Michael, Dorsetshire. Lawrence's son Henry was father of Edward Hyde, earl of Clarendon (*q.v.*), whose second son by his second wife was Lawrence, earl of Rochester (*q.v.*); another son was Sir Lawrence Hyde, attorney-general to Anne of Denmark, James I.'s consort; and a third son was Sir Nicholas Hyde (d. 1631), chief-justice of England. Sir Nicholas entered parliament in 1601 and soon became prominent as an opponent of the court, though he does not appear to have distinguished himself in the law. Before long, however, he deserted the popular party, and in 1626 he was employed by the duke of Buckingham in his defence to impeachment by the Commons; and in the following year he was appointed chief-justice of the king's bench, in which office it fell to him to give judgment in the celebrated case of Sir Thomas Darnell and others who had been committed to prison on warrants signed by members of the privy council, which contained no statement of the nature of the charge against the prisoners. In answer to the writ of *habeas corpus* the attorney-general relied on the prerogative of the crown, supported by a precedent of Queen Elizabeth's reign. Hyde, three other judges concurring, decided in favour of the crown, but without going so far as to declare the right of the crown to refuse indefinitely to show cause against the discharge of the prisoners. In 1629 Hyde was one of the judges who condemned Eliot, Holles and Valentine for conspiracy in parliament to resist the king's orders; refusing to admit their plea that they could not be called upon to answer out of parliament for acts done in parliament. Sir Nicholas Hyde died in August 1631.

Sir Lawrence Hyde, attorney-general to Anne of Denmark, had eleven sons, four of whom were men of some mark. Henry was an ardent royalist who accompanied Charles II. to the continent, and returning to England was beheaded in 1650; Alexander (1598–1667) became bishop of Salisbury in 1665; Edward (1607–1659) was a royalist divine who was nominated dean of Windsor in 1658, but died before taking up the appointment, and who was the author of many controversial works in Anglican theology; and Robert (1595–1665) became recorder of Salisbury and represented that borough in the Long Parliament, in which he professed royalist principles, voting against the attainder of Strafford. Having been imprisoned and deprived of his recordership by the parliament in 1645/6, Robert Hyde gave refuge to Charles II. on his flight from Worcester in 1651, and on the Restoration he was knighted and made a judge of the common pleas. He died in 1665. Henry Hyde (1672–1753), only son of Lawrence, earl of Rochester, became 4th earl of Clarendon and 2nd earl of Rochester, both of which titles became extinct at his death. He was in no way distinguished, but his wife Jane Hyde, countess of Clarendon and Rochester (d. 1725), was a famous beauty celebrated by the homage of Swift, Prior and Pope, and by the groundless scandal of Lady Mary Wortley Montagu. Two of her daughters, Jane, countess of Essex, and Catherine, duchess of Queensberry, were also famous beauties of the reign of Queen Anne. Her son, Henry Hyde (1710–1753), known as Viscount Cornbury, was a Tory and Jacobite member of parliament, and an intimate friend of Bolingbroke, who addressed to him his *Letters on the Study and Use of History*, and *On the Spirit of Patriotism*. In 1750 Lord Cornbury was created Baron Hyde of Hindon, but, as he predeceased his father, this title reverted to the latter and became extinct at his death. Lord Cornbury was celebrated as a wit and a conversationalist. By his will he bequeathed the papers of his great-grandfather, Lord Clarendon, the historian, to the Bodleian Library at Oxford.

See Lord Clarendon, *The Life of Edward, Earl of Clarendon* (3 vols., Oxford, 1827); Edward Foss, *The Judges of England* (London, 1848–1864); Anthony à Wood, *Athenae oxonienses* (London, 1813–1820); Samuel Pepys, *Diary and Correspondence*, edited by Lord Braybrooke (4 vols., London, 1854).

HYDE, THOMAS (1636–1703), English Orientalist, was born at Billingsley, near Bridgnorth, in Shropshire, on the 29th of June 1636. He inherited his taste for linguistic studies, and received his first lessons in some of the Eastern tongues, from his father, who was rector of the parish. In his sixteenth year Hyde entered King's College, Cambridge, where, under Wheelock, professor of Arabic, he made rapid progress in Oriental languages, so that, after only one year of residence, he was invited to London to assist Brian Walton in his edition of the *Polyglott Bible*. Besides correcting the Arabic, Persic and Syriac texts for that work, Hyde transcribed into Persic characters the Persian translation of the Pentateuch, which had been printed in Hebrew letters at Constantinople in 1546. To this work, which Archbishop Ussher had thought well-nigh impossible even for a native of Persia, Hyde appended the Latin version which accompanies it in the *Polyglott*. In 1658 he was chosen Hebrew reader at Queen's College, Oxford, and in 1659, in consideration of his erudition in Oriental tongues, he was admitted to the degree of M.A. In the same year he was appointed under-keeper of the Bodleian Library, and in 1665 librarian-in-chief. Next year he was collated to a prebend at Salisbury, and in 1673 to the archdeaconry of Gloucester, receiving the degree of D.D. shortly afterwards. In 1691 the death of Edward Pococke opened up to Hyde the Laudian professorship of Arabic; and in 1697, on the deprivation of Roger Altham, he succeeded to the regius chair of Hebrew and a canonry of Christ Church. Under Charles II., James II. and William III. Hyde discharged the duties of Eastern interpreter to the court. Worn out by his unremitting labours, he resigned his librarianship in 1701, and died at Oxford on the 18th of February 1703. Hyde, who was one of the first to direct attention to the vast treasures of Oriental antiquity, was an excellent classical scholar, and there was hardly an Eastern tongue accessible to foreigners with which he was not familiar. He had even acquired Chinese, while his writings are the best testimony to his mastery of Turkish, Arabic, Syriac, Persian, Hebrew and Malay.

In his chief work, *Historia religionis veterum Persarum* (1700), he made the first attempt to correct from Oriental sources the errors of the Greek and Roman historians who had described the religion of the ancient Persians. His other writings and translations comprise *Tabulae longitudinum et latitudinum stellarum fixarum ex observatione principis Ulugh Beighi* (1665), to which his notes have given additional value; *Quatuor evangelia et acta apostolorum lingua Malaica, caracteribus Europaeis* (1677); *Epistola de mensuris et ponderibus serum sive sinensium* (1688), appended to Bernard's *De mensuris et ponderibus antiquis; Abraham Peritsol itinera mundi* (1691); and *De ludis orientalibus libri II.* (1694).

With the exception of the *Historia religionis*, which was republished by Hunt and Costard in 1760, the writings of Hyde, including some unpublished MSS., were collected and printed by Dr Gregory Sharpe in 1767 under the title *Syntagma dissertationum quas olim... Thomas Hyde separatim edidit.* There is a life of the author prefixed. Hyde also published a catalogue of the Bodleian Library in 1674.

HYDE, a market town and municipal borough in the Hyde parliamentary division of Cheshire, England, 7½ m. E. of Manchester, by the Great Central railway. Pop. (1901) 32,766. It lies in the densely populated district in the north-east of the county, on the river Tame, which here forms the boundary of Cheshire with Lancashire. To the east the outlying hills of the Peak district of Derbyshire rise abruptly. The town has cotton weaving factories, spinning mills, print-works, iron foundries and machine works; also manufactures of hats and margarine. There are extensive coal mines in the vicinity. Hyde is wholly of modern growth, though it contains a few ancient houses, such as Newton Hall, in the part of the town so called. The old family of Hyde held possession of the manor as early as the reign of John. The borough, incorporated in 1881, is under a mayor, 6 aldermen and 18 councillors. Area, 3081 acres.

HYDE DE NEUVILLE, JEAN GUILLAUME, Baron (1776–1857), French politician, was born at La Charité-sur-Loire (Nièvre) on the 24th of January 1776, the son of Guillaume Hyde, who belonged to an English family which had emigrated with the Stuarts after the rebellion of 1745. He was only seventeen when he successfully defended a man denounced by Fouché before the revolutionary tribunal of Nevers. From 1793 onwards he was an active agent of the exiled princes; he took part in the Royalist rising in Berry in 1796, and after the *coup d'état* of the 18th Brumaire (November 9, 1799) tried to persuade Bonaparte to recall the Bourbons. An accusation of complicity in the infernal machine conspiracy of 1800–1801 was speedily retracted, but Hyde de Neuville retired to the United States, only to return after the Restoration. He was sent by Louis XVIII. to London to endeavour to persuade the British government to transfer Napoleon to a remoter and safer place of exile than the isle of Elba, but the negotiations were cut short by the emperor's return to France in March 1815. In January 1816 de Neuville became French ambassador at Washington, where he negotiated a commercial treaty. On his return in 1821 he declined the Constantinople embassy, and in November 1822 was elected deputy for Cosne. Shortly afterwards he was appointed French ambassador at Lisbon, where his efforts to oust British influence culminated, in connexion with the *coup d'état* of Dom Miguel (April 30, 1824), in his suggestion to the Portuguese minister to invite the armed intervention of Great Britain. It was assumed that this would be refused, in view of the loudly proclaimed British principle of non-intervention, and that France would then be in a position to undertake a duty that Great Britain had declined. The scheme broke down, however, owing to the attitude of the reactionary party in the government of Paris, which disapproved of the Portuguese constitution. This destroyed his influence at Lisbon, and he returned to Paris to take his seat in the Chamber of Deputies. In spite of his pronounced Royalism, he now showed Liberal tendencies, opposed the policy of Villèle's cabinet, and in 1828 became a member of the moderate administration of Martignac as minister of marine. In this capacity he showed active sympathy with the cause of Greek independence. During the Polignac ministry (1829–1830) he was again in opposition, being a firm upholder of the charter; but after the revolution of July 1830 he entered an all but solitary protest against the exclusion of the legitimate line of the Bourbons from the throne, and resigned his seat. He died in Paris on the 28th of May 1857.

His *Mémoires et souvenirs* (3 vols., 1888), compiled from his notes by his nieces, the vicomtesse de Bardonnet and the baronne Laurenceau, are of great interest for the Revolution and the Restoration.

HYDE PARK, a small township of Norfolk county, Massachusetts, U.S.A., about 8 m. S.W. of the business centre of Boston. Pop. (1890) 10,193; (1900) 13,244, of whom 3805 were foreign-born; (1910 census) 15,507. Its area is about 4½ sq. m. It is traversed by the New York, New Haven & Hartford railway, which has large repair shops here, and by the Neponset river and smaller streams. The township contains the villages of Hyde Park, Readville (in which there is the famous "Weil" trotting-track), Fairmount, Hazelwood and Clarendon Hills. Until about 1856 Hyde Park was a farmstead. The value of the total factory product increased from $4,383,959 in 1900 to $6,739,307 in 1905, or 53·7%. In 1868 Hyde Park was incorporated as a township, being formed of territory taken from Dorchester, Dedham and Milton.

HYDERABAD, or Haidarabad, a city and district of British India, in the Sind province of Bombay. The city stands on a hill about 3 m. from the left bank of the Indus, and had a population in 1901 of 69,378. Upon the site of the present fort is supposed to have stood the ancient town of Nerankot, which in the 8th century submitted to Mahommed bin Kasim. In 1768 the present city was founded by Ghulam Shah Kalhora; and it remained the capital of Sind until 1843, when, after the battle of Meeanee, it was surrendered to the British, and the capital transferred to Karachi. The city is built on the most northerly hills of the Ganga range, a site of great natural strength. In the fort, which covers an area of 36 acres, is the arsenal of the province, transferred thither from Karachi in 1861, and the palaces of the ex-mirs of Sind. An excellent water supply is derived from the Indus. In addition to manufactures of silk, gold and silver embroidery, lacquered ware and pottery, there are three factories for ginning cotton. There are three high schools, training colleges for masters and mistresses, a medical school, an agricultural school for village officials, and a technical school. The city suffered from plague in 1896–1897.

The District of Hyderabad has an area of 8291 sq. m., with a population in 1901 of 989,030, showing an increase of 15% in the decade. It consists of a vast alluvial plain, on the left bank of the Indus, 216 m. long and 48 broad. Fertile along the course of the river, it degenerates towards the east into sandy wastes, sparsely populated, and defying cultivation. The monotony is relieved by the fringe of forest which marks the course of the river, and by the avenues of trees that line the irrigation channels branching eastward from this stream. The south of the district has a special feature in its large natural water-courses (called *dhoras*) and basin-like shallows (*chhaus*), which retain the rains for a long time. A limestone range called the Ganga and the pleasant frequency of garden lands break the monotonous landscape. The principal crops are millets, rice, oil-seeds, cotton and wheat, which are dependent on irrigation, mostly from government canals. There is a special manufacture at Hala of glazed pottery and striped cotton cloth. Three railways traverse the district: (1) one of the main lines of the North-Western system, following the Indus valley and crossing the river near Hyderabad; (2) a broad-gauge branch running south to Badin, which will ultimately be extended to Bombay; and (3) a metre-gauge line from Hyderabad city into Rajputana.

HYDERABAD, Haidarabad, also known as the Nizam's Dominions, the principal native state of India in extent, population and political importance; area, 82,698 sq. m.; pop. (1901) 11,141,142, showing a decrease of 3·4% in the decade; estimated revenue 4½ crores of Hyderabad rupees (£2,500,000). The state occupies a large portion of the eastern plateau of the Deccan. It is bounded on the north and north-east by Berar, on the south and south-east by Madras, and on the west by Bombay. The country presents much variety of surface and feature; but it may be broadly divided into two tracts, distinguished from one another geologically and ethnically, which are locally known from the languages spoken as Telingana and Marathwara. In some parts it is mountainous, wooded and picturesque, in others flat and undulating. The open country includes lands of all descriptions, including many rich and fertile plains, much good land not yet brought under cultivation, and numerous tracts too sterile ever to be cultivated. In the north-west the geological formations are volcanic, consisting principally of trap, but in some parts of basalt; in the middle, southern and south-western parts the country is overlaid with gneissic formations. The territory is well watered, rivers being numerous, and tanks or artificial pieces of water abundant, especially in Telingana. The principal rivers are the Godavari, with its tributaries the Dudna, Manjira and Pranhita; the Wardha, with its tributary the Penganga; and the Kistna, with its tributary the Tungabhadra. The climate may be considered in general good; and as there are no arid bare deserts, hot winds are little felt.

More than half the revenue of the state is derived from the land, and the development of the country by irrigation and railways has caused considerable expansion in this revenue, though the rate of increase in the decade 1891–1901 was retarded by a succession of unfavourable seasons. The soil is generally fertile, though in some parts it consists of *chilka*, a red and gritty mould little fitted for purposes of agriculture. The principal crops are millets of various kinds, rice, wheat, oil-seeds, cotton, tobacco, sugar-cane, and fruits and garden produce in great variety. Silk, known as *tussur*, the produce of a wild species of worm, is utilized on a large scale. Lac, suitable for use as a resin or dye, gums and oils are found in great quantities. Hides, raw and tanned, are articles of some importance in commerce. The principal exports are cotton, oil-seeds, country-clothes and hides; the imports are salt, grain, timber, European piece-goods and hardware. The mineral wealth of the state consists of coal, copper, iron, diamonds and gold; but the development of these resources has not hitherto been very successful. The only coal mine now worked is the large one at Singareni, with an annual out-turn of nearly half a million tons. This coal has enabled the nizam's guaranteed state railway to be worked so cheaply that it now returns a handsome profit to the state. It also gives encouragement to much-needed schemes of railway extension, and to the erection of cotton presses and of spinning and weaving mills. The Hyderabad-Godavari railway (opened in 1901) traverses a rich cotton country, and cotton presses have been erected along the line. The currency of the state is based on the *hali sikka*, which contains approximately the same weight of silver as the British rupee, but its exchange value fell heavily after 1893, when free coinage ceased in the mint. In 1904, however, a new coin (the Mahbubia rupee) was minted; the supply was regulated, and the rate of exchange became about 115=100 British rupees. The state suffered from famine during 1900, the total number of persons in receipt of relief rising to nearly 500,000 in June of that year. The nizam met the demands for relief with great liberality.

The nizam of Hyderabad is the principal Mahommedan ruler in India. The family was founded by Asaf Jah, a distinguished Turkoman soldier of the emperor Aurangzeb, who in 1713 was appointed subahdar of the Deccan, with the title of nizam-ul-mulk (regulator of the state), but eventually threw off the control of the Delhi court. Azaf Jah's death in 1748 was followed by an internecine struggle for the throne among his descendants, in which the British and the French took part. At one time the French nominee, Salabat Jang, established himself with the help of Bussy. But finally, in 1761, when the British had secured their predominance throughout southern India, Nizam Ali took his place and ruled till 1803. It was he who confirmed the grant of the Northern Circars in 1766, and joined in the two wars against Tippoo Sultan in 1792 and 1799. The additions of territory which he acquired by these wars was afterwards (1800) ceded to the British, as payment for the subsidiary force which he had undertaken to maintain. By a later treaty in 1853, the districts known as Berar were "assigned" to defray the cost of the Hyderabad contingent. In 1857 when the Mutiny broke out, the attitude of Hyderabad as the premier native state and the cynosure of the Mahommedans in India became a matter of extreme importance; but Afzul-ud-Dowla, the father of the present ruler, and his famous minister, Sir Salar Jang, remained loyal to the British. An attack on the residency was repulsed, and the Hyderabad contingent displayed their loyalty in the field against the rebels. In 1902 by a treaty made by Lord Curzon, Berar was leased in perpetuity to the British government, and the Hyderabad contingent was merged in the Indian army. The nizam Mir Mahbub Ali Khan Bahadur, Asaf Jah, a direct descendant of the famous nizam-ul-mulk, was born on the 18th of August 1866. On the death of his father in 1869 he succeeded to the throne as a minor, and was invested with full powers in 1884. He is notable as the originator of the Imperial Service Troops, which now form the contribution of the native chiefs to the defence of India. On the occasion of the Panjdeh incident in 1885 he made an offer of money and men, and subsequently on the occasion of Queen Victoria's Jubilee in 1887 he offered 20 lakhs (£130,000) annually for three years for the purpose of frontier defence. It was finally decided that the native chiefs should maintain small but well-equipped bodies of infantry and cavalry for imperial defence. For many years past the Hyderabad finances were in a very unhealthy condition; the expenditure consistently outran the revenue, and the nobles, who held their tenure under an obsolete feudal system, vied with each other in ostentatious extravagance. But in 1902, on the revision of the Berar agreement, the nizam received 25 lakhs (£167,000) a year for the rent of Berar, thus substituting a fixed for a fluctuating source of income, and a British financial adviser was appointed for the purpose of reorganizing the resources of the state.

See S. H. Bilgrami and C. Willmott, *Historical and Descriptive Sketch of the Nizam's Dominions* (Bombay, 1883–1884).

HYDERABAD or Haidarabad, capital of the above state, is situated on the right bank of the river Musi, a tributary of the Kistna, with Golconda to the west, and the residency and its bazaars and the British cantonment of Secunderabad to the north-east. It is the fourth largest city in India; pop. (1901) 448,466, including suburbs and cantonment. The city itself is in shape a parallelogram, with an area of more than 2 sq. m. It was founded in 1589 by Mahommed Kuli, fifth of the Kutb Shahi kings, of whose period several important buildings remain as monuments. The principal of these is the Char Minar or Four Minarets (1591). The minarets rise from arches facing the cardinal points, and stand in the centre of the city, with four roads radiating from their base. The Ashur Khana (1594), a ceremonial building, the hospital, the Gosha Mahal palace and the Mecca mosque, a sombre building designed after a mosque at Mecca, surrounding a paved quadrangle 360 ft. square, were the other principal buildings of the Kutb Shahi period, though the mosque was only completed in the time of Aurangzeb. The city proper is surrounded by a stone wall with thirteen gates, completed in the time of the first nizam, who made Hyderabad his capital. The suburbs, of which the most important is Chadarghat, extend over an additional area of 9 sq. m. There are several fine palaces built by various nizams, and the British residency is an imposing building in a large park on the left bank of the Musi, N.E. of the city. The bazaars surrounding it, and under its jurisdiction, are extremely picturesque and are thronged with natives from all parts of India. Four bridges crossed the Musi, the most notable of which was the Purana Pul, of 23 arches, built in 1593. On the 27th and 28th of September 1908, however, the Musi, swollen by torrential rainfall (during which 15 in. fell in 36 hours), rose in flood to a height of 12 ft. above the bridges and swept them away. The damage done was widespread; several important buildings were involved, including the palace of Salar Jang and the Victoria zenana hospital, while the beautiful grounds of the residency were destroyed. A large and densely populated part of the city was wrecked, and thousands of lives were lost. The principal educational establishments are the Nizam college (first grade), engineering, law, medical, normal, industrial and Sanskrit schools, and a number of schools for Europeans and Eurasians. Hyderabad is an important centre of general trade, and there is a cotton mill in its vicinity. The city is supplied with water from two notable works, the Husain Sagar and the Mir Alam, both large lakes retained by great dams. Secunderabad, the British military cantonment, is situated $5\frac{1}{2}$ m. N. of the residency; it includes Bolaram, the former headquarters of the Hyderabad contingent.

HYDER ALI, or Haidar 'Ali (*c.* 1722–1782), Indian ruler and commander. This Mahommedan soldier-adventurer, who, followed by his son Tippoo, became the most formidable Asiatic rival the British ever encountered in India, was the great-grandson of a *fakir* or wandering ascetic of Islam, who had found his way from the Punjab to Gulburga in the Deccan, and the second son of a *naik* or chief constable at Budikota, near Kolar in Mysore. He was born in 1722, or according to other authorities 1717. An elder brother, who like himself was early turned out into the world to seek his own fortune, rose to command a brigade in the Mysore army, while Hyder, who never learned to read or write, passed the first years of his life aimlessly in sport and sensuality, sometimes, however, acting as the agent of his brother, and meanwhile acquiring a useful familiarity with the tactics of the French when at the height of their reputation under Dupleix. He is said to have induced his brother to employ a Parsee to purchase artillery and small arms from the Bombay government, and to enrol some thirty sailors of different European nations as gunners, and is thus credited with having been "the first Indian who formed a corps of sepoys armed with firelocks and bayonets, and who had a train of artillery served by Europeans." At the siege of Devanhalli (1749) Hyder's services attracted the attention of Nanjiraj, the minister of the raja of Mysore, and he at once received an independent command; within the next twelve years his energy and ability had made him completely master of minister and raja alike, and in everything but in name he was ruler of the kingdom. In 1763 the conquest of Kanara gave him possession of the treasures of Bednor, which he resolved to make the most splendid capital in India, under his own name, thenceforth changed from Hyder Naik into Hyder Ali Khan Bahadur; and in 1765 he retrieved previous defeat at the hands of the Mahrattas by the destruction of the Nairs or military caste of the Malabar coast, and the conquest of Calicut. Hyder Ali now began to occupy the serious attention of the Madras government, which in 1766 entered into an agreement with the nizam to furnish him with troops to be used against the common foe. But hardly had this alliance been formed when a secret arrangement was come to between the two Indian powers, the result of which was that Colonel Smith's small force was met with a united army of 80,000 men and 100 guns. British dash and sepoy fidelity, however, prevailed, first in the battle of Chengam (September 3rd, 1767), and again still more remarkably in that of Tiruvannamalai (Trinomalai). On the loss of his recently made fleet and forts on the western coast, Hyder Ali now offered overtures for peace; on the rejection of these, bringing all his resources and strategy into play, he forced Colonel Smith to raise the siege of Bangalore, and brought his army within 5 m. of Madras. The result was the treaty of April 1769, providing for the mutual restitution of all conquests, and for mutual aid and alliance in defensive war; it was followed by a commercial treaty in 1770 with the authorities of Bombay. Under these arrangements Hyder Ali, when defeated by the Mahrattas in 1772, claimed British assistance, but in vain; this breach of faith stung him to fury, and thenceforward he and his son did not cease to thirst for vengeance. His time came when in 1778 the British, on the declaration of war with France, resolved to drive the French out of India. The capture of Mahé on the coast of Malabar in 1779, followed by the annexation of lands belonging to a dependent of his own, gave him the needed pretext. Again master of all that the Mahrattas had taken from him, and with empire extended to the Kistna, he descended through the passes of the Ghats amid burning villages, reaching Conjeeveram, only 45 m. from Madras, unopposed. Not till the smoke was seen from St Thomas's Mount, where Sir Hector Munro commanded some 5200 troops, was any movement made; then, however, the British general sought to effect a junction with a smaller body under Colonel Baillie recalled from Guntur. The incapacity of these officers, notwithstanding the splendid courage of their men, resulted in the total destruction of Baillie's force of 2800 (September the 10th, 1780). Warren Hastings sent from Bengal Sir Eyre Coote, who, though repulsed at Chidambaram, defeated Hyder thrice successively in the battles of Porto Novo, Pollilur and Sholingarh, while Tippoo was forced to raise the siege of Wandiwash, and Vellore was provisioned. On the arrival of Lord Macartney as governor of Madras, the British fleet captured Negapatam, and forced Hyder Ali to confess that he could never ruin a power which had command of the sea. He had sent his son Tippoo to the west coast, to seek the assistance of the French fleet, when his death took place suddenly at Chittur in December 1782.

See L. B. Bowring, *Haidar Ali and Tipu Sultan*, "Rulers of India" series (1893). For the personal character and administration of Hyder Ali see the *History of Hyder Naik*, written by Mir Hussein Ali Khan Kirmani (translated from the Persian by Colonel Miles, and published by the Oriental Translation Fund), and the curious work written by M. Le Maître de La Tour, commandant of his artillery (*Histoire d'Hayder-Ali Khan*, Paris, 1783). For the whole life and times see Wilks, *Historical Sketches of the South of India* (1810–1817); Aitchison's *Treaties*, vol. v. (2nd ed., 1876); and Pearson, *Memoirs of Schwartz* (1834).

HYDRA (or Sidra, Nidra, Idero, &c.; anc. *Hydrea*), an island of Greece, lying about 4 m. off the S.E. coast of Argolis in the Peloponnesus, and forming along with the neighbouring island of Dokos (Dhoko) the Bay of Hydra. Pop. about 6200. The greatest length from south-west to north-east is about 11 m., and the area is about 21 sq. m.; but it is little better than a rocky and treeless ridge with hardly a patch or two of arable soil. Hence the epigram of Antonios Kriezes to the queen of Greece: "The island produces prickly pears in abundance, splendid sea captains and excellent prime ministers." The highest point, Mount Ere, so called (according to Miaoules) from the Albanian word for wind, is 1958 ft. high. The next in importance is known as the Prophet Elias, from the large convent of that name on its summit. It was there that the patriot Theodorus Kolokotrones was imprisoned, and a large pine tree is still called after him. The fact that in former times the island was richly clad with woods is indicated by the name still employed by the Turks, *Tchamliza*, the place of pines; but it is only in some favoured spots that a few trees are now to be found. Tradition also has it that it was once a well-watered island (hence the designation Hydrea), but the inhabitants are now wholly dependent on the rain supply, and they have sometimes had to bring water from the mainland. This lack of fountains is probably to be ascribed in part to the effect of earthquakes, which are not infrequent; that of 1769 continued for six whole days. Hydra, the chief town, is built near the middle of the northern coast, on a very irregular site, consisting of three hills and the intervening ravines. From the sea its white and handsome houses present a picturesque appearance, and its streets though narrow are clean and attractive. Besides the principal harbour, round which the town is built, there are three other ports on the north coast—Mandraki, Molo, Panagia, but none of them is sufficiently sheltered. Almost all the population of the island is collected in the chief town, which is the seat of a bishop, and has a local court, numerous churches and a high school. Cotton and silk weaving, tanning and shipbuilding are carried on, and there is a fairly active trade.

Hydra was of no importance in ancient times. The only fact in its history is that the people of Hermione (a city on the neighbouring mainland now known by the common name of *Kastri*) surrendered it to Samian refugees, and that from these the people of Troezen received it in trust. It appears to be completely ignored by the Byzantine chroniclers. In 1580 it was chosen as a refuge by a body of Albanians from Kokkinyas in Troezenia; and other emigrants followed in 1590, 1628, 1635, 1640, &c. At the close of the 17th century the Hydriotes took part in the reviving commerce of the Peloponnesus; and in course of time they extended their range. About 1716 they began to build *sakturia* (of from 10 to 15 tons burden), and to visit the islands of the Aegean; not long after they introduced the *latinadika* (40–50 tons), and sailed as far as Alexandria, Constantinople, Trieste and Venice; and by and by they ventured to France and even America. From the grain trade of south Russia more especially they derived great wealth. In 1813 there were about 22,000 people in the island, and of these 10,000 were seafarers. At the time of the outbreak of the war of Greek independence the total population was 28,190, of whom 16,460 were natives and the rest foreigners. One of their chief families, the Konduriotti, was worth £2,000,000. Into the struggle the Hydriotes flung themselves with rare enthusiasm and devotion, and the final deliverance of Greece was mainly due to the service rendered by their fleets.

D. Kriezes, *Ἱστορία τῆς νήσου Ὕδρας* (Patras, 1860).

HYDRA (watersnake), in Greek legend, the offspring of Typhon and Echidna, a gigantic monster with nine heads (the number is variously given), the centre one being immortal. Its haunt was a hill beneath a plane tree near the river Amymone, in the marshes of Lerna by Argos. The destruction of this Lernaean hydra was one of the twelve "labours" of Heracles, which he accomplished with the assistance of Iolaus. Finding that as soon as one head was cut off two grew up in its place, they burnt out the roots with firebrands, and at last severed the immortal head from the body, and buried it under a mighty block of rock. The arrows dipped by Heracles in the poisonous blood or gall of the monster ever afterwards inflicted fatal wounds. The generally accepted interpretation of the legend is that "the hydra denotes the damp, swampy ground of Lerna with its numerous springs (κεφαλαί, heads); its poison the miasmic vapours rising from the stagnant water; its death at the hands of Heracles the introduction of the culture and consequent purification of the soil" (Preller). A euhemeristic explanation is given by Palaephatus (39). An ancient king named Lernus occupied a small citadel named Hydra, which was defended by 50 bowmen. Heracles besieged the citadel and hurled firebrands at the garrison. As often as one of the defenders fell, two others at once stepped into his place. The citadel was finally taken with the assistance of the army of Iolaus and the garrison slain.

See Hesiod, *Theog.*, 313; Euripides, *Hercules furens*, 419; Pausanias ii. 37; Apollodorus ii. 5, 2; Diod. Sic. iv. 11; Roscher's *Lexikon der Mythologie*. In the article GREEK ART, fig. 20 represents the slaying of the Lernaean hydra by Heracles.

HYDRA, in astronomy, a constellation of the southern hemisphere, mentioned by Eudoxus (4th century B.C.) and Aratus (3rd century B.C.), and catalogued by Ptolemy (27 stars), Tycho Brahe (19) and Hevelius (31). Interesting objects are: the nebula *H. IV. 27 Hydrae*, a planetary nebula, gaseous and whose light is about equal to an 8th magnitude star; *ε Hydrae*, a beautiful triple star, composed of two yellow stars of the 4th and 6th magnitudes, and a blue star of the 7th magnitude; *R. Hydrae*, a long period (425 days) variable, the range in magnitude being from 4 to 9·7; and *U. Hydrae*, an irregularly variable, the range in magnitude being 4·5 to 6.

HYDRACRYLIC ACID (ethylene lactic acid), $CH_2OH·CH_2·CO_2H$, an organic oxyacid prepared by acting with silver oxide and water on β-iodopropionic acid, or from ethylene by the addition of hypochlorous acid, the addition product being then treated with potassium cyanide and hydrolysed by an acid. It may also be prepared by oxidizing the trimethylene glycol obtained by the action of hydrobromic acid on allylbromide. It is a syrupy liquid, which on distillation is resolved into water and the unsaturated acrylic acid, $CH_2: CH·CO_2H$. Chromic and nitric acids oxidize it to oxalic acid and carbon dioxide. Hydracrylic aldehyde, $CH_2OH·CH_2·CHO$, was obtained in 1904 by J. U. Nef (*Ann.* 335, p. 219) as a colourless oil by heating acrolein with water. Dilute alkalis convert it into crotonaldehyde, $CH_3·CH : CH·CHO$.

HYDRANGEA, a popular flower, the plant to which the name is most commonly applied being *Hydrangea Hortensia*, a low deciduous shrub, producing rather large oval strongly-veined leaves in opposite pairs along the stem. It is terminated by a massive globular corymbose head of flowers, which remain a long period in an ornamental condition. The normal colour of the flowers, the majority of which have neither stamens nor pistil, is pink; but by the influence of sundry agents in the soil, such as alum or iron, they become changed to blue. There are numerous varieties, one of the most noteworthy being "Thomas Hogg" with pure white flowers. The part of the inflorescence which appears to be the flower is an exaggerated expansion of the sepals, the other parts being generally abortive. The perfect flowers are small, rarely produced in the species above referred to, but well illustrated by others, in which they occupy the inner parts of the corymb, the larger showy neuter flowers being produced at the circumference.

There are upwards of thirty species, found chiefly in Japan, in the mountains of India, and in North America, and many of them are familiar in gardens. *H. Hortensia* (a species long known in cultivation in China and Japan) is the most useful for decoration, as the head of flowers lasts long in a fresh state, and by the aid of forcing can be had for a considerable period for the ornamentation of the greenhouse and conservatory. Their natural flowering season is towards the end of the summer, but they may be had earlier by means of forcing. *H. japonica* is another fine conservatory plant, with foliage and habit much resembling the last named, but this has flat corymbs of flowers, the central ones small and perfect, and the outer ones only enlarged and neuter. This also produces pink or blue flowers under the influence of different soils.

The Japanese species of hydrangea are sufficiently hardy to grow in any tolerably favourable situation, but except in the most sheltered localities they seldom blossom to any degree of perfection in the open air, the head of blossom depending on the uninjured development of a well-ripened terminal bud, and this growth being frequently affected by late spring frosts. They are much more useful for pot-culture indoors, and should be reared from cuttings of shoots having the terminal bud plump and prominent, put in during summer, these developing a single head of flowers the succeeding summer. Somewhat larger plants may be had by nipping out the terminal bud and inducing three or four shoots to start in its place, and these, being steadily developed and well ripened, should each yield its inflorescence in the following summer, that is, when two years old. Large plants grown in tubs and vases are fine subjects for large conservatories, and useful for decorating terrace walks and similar places during summer, being housed in winter, and started under glass in spring.

Hydrangea paniculata var. *grandiflora* is a very handsome plant; the branched inflorescence under favourable circumstances is a yard or more in length, and consists of large spreading masses of crowded white neuter flowers which completely conceal the few inconspicuous fertile ones. The plant attains a height of 8 to 10 ft. and when in flower late in summer and in autumn is a very attractive object in the shrubbery.

The Indian and American species, especially the latter, are quite hardy, and some of them are extremely effective.

HYDRASTINE, $C_{21}H_{21}NO_6$, an alkaloid found with berberine in the root of golden seal, *Hydrastis canadensis*, a plant indigenous to North America. It was discovered by Durand in 1851, and its chemistry formed the subject of numerous communications by E. Schmidt and M. Freund (see *Ann.*, 1892, 271, p. 311) who, aided by P. Fritsch (*Ann.*, 1895, 286, p. 1), established its constitution. It is related to narcotine, which is methoxy hydrastine. The root of golden seal is used in medicine under the name hydrastis rhizome, as a stomachic and nervine stimulant.

HYDRATE, in chemistry, a compound containing the elements of water in combination; more specifically, a compound containing the monovalent hydroxyl or OH group. The first and more general definition includes substances containing water of crystallization; such salts are said to be hydrated, and when deprived of their water to be dehydrated or anhydrous. Compounds embraced by the second definition are more usually termed *hydroxides*, since at one time they were regarded as combinations of an oxide with water, for example, calcium oxide or lime when slaked with water yielded calcium hydroxide, written formerly as $CaO·H_2O$. The general formulae of hydroxides are: $M^{i}·OH$, $M^{ii}(OH)_2$, $M^{iii}(OH)_3$, $M^{iv}(OH)_4$, &c., corresponding to the oxides $M_2{}^{i}O$, $M^{ii}O$, $M_2{}^{iii}O_3$, $M^{iv}O_2$, &c., the Roman index denoting the valency of the element. There is an important difference between non-metallic and metallic hydroxides; the former are invariably acids (oxyacids), the latter are more usually basic, although acidic metallic oxides yield acidic hydroxides. Elements exhibiting strong basigenic or oxygenic characters yield the most stable hydroxides; in other words, stable hydroxides are associated with elements belonging to the extreme groups of the periodic system, and unstable hydroxides with the central members. The most stable basic hydroxides are those of the alkali metals, viz. lithium, sodium, potassium, rubidium and caesium, and of the alkaline earth metals, viz. calcium, barium and strontium; the most stable acidic hydroxides are those of the elements placed in groups VB, VIB and VIIB of the periodic table.

HYDRAULICS (Gr. ὕδωρ, water, and αὐλός, a pipe), the branch of engineering science which deals with the practical applications of the laws of hydromechanics.

I. THE DATA OF HYDRAULICS[1]

§ 1. *Properties of Fluids.*—The fluids to which the laws of practical hydraulics relate are substances the parts of which possess very great mobility, or which offer a very small resistance to distortion independently of inertia. Under the general heading Hydromechanics a fluid is defined to be a substance which yields continually to the slightest tangential stress, and hence in a fluid at rest there can be no tangential stress. But, further, in fluids such as water, air, steam, &c., to which the present division of the article relates, the tangential stresses that are called into action between contiguous portions during distortion or change of figure are always small compared with the weight, inertia, pressure, &c., which produce the visible motions it is the object of hydraulics to estimate. On the other hand, while a fluid passes easily from one form to another, it opposes considerable resistance to change of volume.

It is easily deduced from the absence or smallness of the tangential stress that contiguous portions of fluid act on each other with a pressure which is exactly or very nearly normal to the interface which separates them. The stress must be a pressure, not a tension, or the parts would separate. Further, at any point in a fluid the pressure in all directions must be the same; or, in other words, the pressure on any small element of surface is independent of the orientation of the surface.

§ 2. Fluids are divided into liquids, or incompressible fluids, and gases, or compressible fluids. Very great changes of pressure change the volume of liquids only by a small amount, and if the pressure on them is reduced to zero they do not sensibly dilate. In gases or compressible fluids the volume alters sensibly for small changes of pressure, and if the pressure is indefinitely diminished they dilate without limit.

In ordinary hydraulics, liquids are treated as absolutely incompressible. In dealing with gases the changes of volume which accompany changes of pressure must be taken into account.

§ 3. Viscous fluids are those in which change of form under a continued stress proceeds gradually and increases indefinitely. A very viscous fluid opposes great resistance to change of form in a short time, and yet may be deformed considerably by a small stress acting for a long period. A block of pitch is more easily splintered than indented by a hammer, but under the action of the mere weight of its parts acting for a long enough time it flattens out and flows like a liquid.

All actual fluids are viscous. They oppose a resistance to the relative motion of their parts. This resistance diminishes with the velocity of the relative motion, and becomes zero in a fluid the parts of which are relatively at rest. When the relative motion of different parts of a fluid is small, the viscosity may be neglected without introducing important errors. On the other hand, where there is considerable relative motion, the viscosity may be expected to have an influence too great to be neglected.

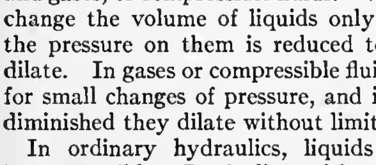

FIG. 1.

Measurement of Viscosity. Coefficient of Viscosity.—Suppose the plane *ab*, fig. 1 of area ω, to move with the velocity V relatively to the surface *cd* and parallel to it. Let the space between be filled with liquid. The layers of liquid in contact with *ab* and *cd* adhere to them. The intermediate layers all offering an equal resistance to shearing or distortion, the rectangle of fluid *abcd* will take the form of the parallelogram *a'b'cd*. Further, the resistance to the motion of *ab* may be expressed in the form

$$R = \kappa\omega V, \tag{1}$$

where κ is a coefficient the nature of which remains to be determined.

[1] Except where other units are given, the units throughout this article are feet, pounds, pounds per sq. ft., feet per second.

If we suppose the liquid between *ab* and *cd* divided into layers as shown in fig. 2, it will be clear that the stress R acts, at each dividing face, forwards in the direction of motion if we consider the upper layer, backwards if we consider the lower layer. Now suppose the original thickness of the layer T increased to nT; if the bounding plane in its new position has the velocity nV, the shearing at each dividing face will be exactly the same as before, and the resistance must therefore be the same. Hence,

$$R = \kappa'\omega(nV). \tag{2}$$

But equations (1) and (2) may both be expressed in one equation if κ and κ' are replaced by a constant varying inversely as the thickness of the layer. Putting $\kappa = \mu/T$, $\kappa' = \mu/nT$,

$$R = \mu\omega V/T;$$

or, for an indefinitely thin layer,

$$R = \mu\omega dV/dt, \tag{3}$$

an expression first proposed by L. M. H. Navier. The coefficient μ is termed the coefficient of viscosity.

According to J. Clerk Maxwell, the value of μ for air at $\theta°$ Fahr. in pounds, when the velocities are expressed in feet per second, is

$$\mu = 0\cdot000\ 000\ 025\ 6(461° + \theta);$$

that is, the coefficient of viscosity is proportional to the absolute temperature and independent of the pressure.

The value of μ for water at 77° Fahr. is, according to H. von Helmholtz and G. Piotrowski,

$$\mu = 0\cdot000\ 001\ 91,$$

the units being the same as before. For water μ decreases rapidly with increase of temperature.

§ 4. When a fluid flows in a very regular manner, as for instance when it flows in a capillary tube, the velocities vary gradually at any moment from one point of the fluid to a neighbouring point. The layer adjacent to the sides of the tube adheres to it and is at rest. The layers more interior than this slide on each other. But the resistance developed by these regular movements is very small. If in large pipes and open channels there were a similar regularity of movement, the neighbouring filaments would acquire, especially near the sides, very great relative velocities. V. J. Boussinesq has shown that the central filament in a semicircular canal of 1 metre radius, and inclined at a slope of only 0·0001, would have a velocity of 187 metres per second,[2] the layer next the boundary remaining at rest. But before such a difference of velocity can arise, the motion of the fluid becomes much more complicated. Volumes of fluid are detached continually from the boundaries, and, revolving, form eddies traversing the fluid in all directions, and sliding with finite relative velocities against those surrounding them. These slidings develop resistances incomparably greater than the viscous resistance due to movements varying continuously from point to point. The movements which produce the phenomena commonly ascribed to fluid friction must be regarded as rapidly or even suddenly varying from one point to another. The internal resistances to the motion of the fluid do not depend merely on the general velocities of translation at different points of the fluid (or what Boussinesq terms the mean local velocities), but rather on the intensity at each point of the eddying agitation. The problems of hydraulics are therefore much more complicated than problems in which a regular motion of the fluid is assumed, hindered by the viscosity of the fluid.

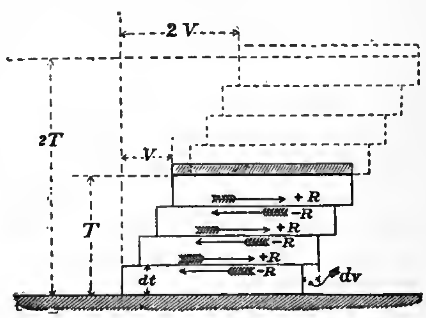

FIG. 2.

Relation of Pressure, Density, and Temperature of Liquids

§ 5. *Units of Volume.*—In practical calculations the cubic foot and gallon are largely used, and in metric countries the litre and cubic metre (= 1000 litres). The imperial gallon is now exclusively used in England, but the United States have retained the old English wine gallon.

[2] *Journal de M. Liouville*, t. xiii. (1868); *Mémoires de l'Académie des Sciences de l'Institut de France*, t. xxiii., xxiv. (1877).

1 cub. ft.	= 6·236 imp. gallons	= 7·481 U.S. gallons.
1 imp. gallon	= 0·1605 cub. ft.	= 1·200 U.S. gallons.
1 U.S. gallon	= 0·1337 cub. ft.	= 0·8333 imp. gallon.
1 litre	= 0·2201 imp. gallon	= 0·2641 U.S. gallon.

Density of Water.—Water at 53° F. and ordinary pressure contains 62·4 lb per cub. ft., or 10 lb per imperial gallon at 62° F. The litre contains one kilogram of water at 4° C. or 1000 kilograms per cubic metre. River and spring water is not sensibly denser than pure water. But average sea water weighs 64 lb per cub. ft. at 53° F. The weight of water per cubic unit will be denoted by G. Ice free from air weighs 57·28 lb per cub. ft. (Leduc).

§ 6. *Compressibility of Liquids.*—The most accurate experiments show that liquids are sensibly compressed by very great pressures, and that up to a pressure of 65 atmospheres, or about 1000 lb per sq. in., the compression is proportional to the pressure. The chief results of experiment are given in the following table. Let V_1 be the volume of a liquid in cubic feet under a pressure p_1 lb per sq. ft., and V_2 its volume under a pressure p_2. Then the cubical compression is $(V_2-V_1)/V_1$, and the ratio of the increase of pressure p_2-p_1 to the cubical compression is sensibly constant. That is, $k=(p_2-p_1)V_1/(V_2-V_1)$ is constant. This constant is termed the elasticity of volume. With the notation of the differential calculus,

$$k=dp\Big/\left(-\frac{dV}{V}\right)=-V\frac{dp}{dV}.$$

Elasticity of Volume of Liquids.

	Canton.	Oersted.	Colladon and Sturm.	Regnault.
Water	45,990,000	45,900,000	42,660,000	44,090,000
Sea water	52,900,000	..	..	..
Mercury	705,300,000	..	626,100,000	604,500,000
Oil	44,090,000	..	..	..
Alcohol	32,060,000	..	23,100,000	..

According to the experiments of Grassi, the compressibility of water diminishes as the temperature increases, while that of ether, alcohol and chloroform is increased.

§ 7. *Change of Volume and Density of Water with Change of Temperature.*—Although the change of volume of water with change of temperature is so small that it may generally be neglected in ordinary hydraulic calculations, yet it should be noted that there is a change of volume which should be allowed for in very exact calculations. The values of ρ in the following short table, which gives data enough for hydraulic purposes, are taken from Professor Everett's *System of Units.*

Density of Water at Different Temperatures.

Temperature. Cent.	Temperature. Fahr.	ρ Density of Water.	G Weight of 1 cub. ft. in lb.	Temperature. Cent.	Temperature. Fahr.	ρ Density of Water.	G Weight of 1 cub. ft. in lb.

The weight per cubic foot has been calculated from the values of ρ, on the assumption that 1 cub. ft. of water at 39·2° Fahr. is 62·425 lb. For ordinary calculations in hydraulics, the density of water (which will in future be designated by the symbol G) will be taken at 62·4 lb per cub. ft., which is its density at 53° Fahr. It may be noted also that ice at 32° Fahr. contains 57·3 lb per cub. ft. The values of ρ are the densities in grammes per cubic centimetre.

§ 8. *Pressure Column. Free Surface Level.*—Suppose a small vertical pipe introduced into a liquid at any point P (fig. 3). Then the liquid will rise in the pipe to a level OO, such that the pressure due to the column in the pipe exactly balances the pressure on its mouth. If the fluid is in motion the mouth of the pipe must be supposed accurately parallel to the direction of motion, or the impact of the liquid at the mouth of the pipe will have an influence on the height of the column. If this condition is complied with, the height h of the column is a measure of the pressure at the point P. Let ω be the area of section of the pipe, h the height of the pressure column, p the intensity of pressure at P; then

$$p\omega=Gh\omega\text{lb},$$
$$p/G=h;$$

that is, h is the height due to the pressure at p. The level OO will be termed the free surface level corresponding to the pressure at P.

Relation of Pressure, Temperature, and Density of Gases

§ 9. *Relation of Pressure, Volume, Temperature and Density in Compressible Fluids.*—Certain problems on the flow of air and steam are so similar to those relating to the flow of water that they are conveniently treated together. It is necessary, therefore, to state as briefly as possible the properties of compressible fluids so far as knowledge of them is requisite in the solution of these problems. Air may be taken as a type of these fluids, and the numerical data here given will relate to air.

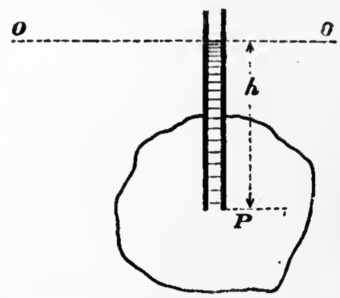

Fig. 3.

Relation of Pressure and Volume at Constant Temperature.—At constant temperature the product of the pressure p and volume V of a given quantity of air is a constant (Boyle's law).

Let p_0 be mean atmospheric pressure (2116·8 lb per sq. ft.), V_0 the volume of 1 lb of air at 32° Fahr. under the pressure p_0. Then

$$p_0V_0=26214. \qquad (1)$$

If G_0 is the weight per cubic foot of air in the same conditions,

$$G_0=1/V_0=2116{\cdot}8/26214=\cdot08075. \qquad (2)$$

For any other pressure p, at which the volume of 1 lb is V and the weight per cubic foot is G, the temperature being 32° Fahr.,

$$pV=p/G=26214;\ \text{or}\ G=p/26214. \qquad (3)$$

Change of Pressure or Volume by Change of Temperature.—Let p_0, V_0, G_0, as before be the pressure, the volume of a pound in cubic feet, and the weight of a cubic foot in pounds, at 32° Fahr. Let p, V, G be the same quantities at a temperature t (measured strictly by the air thermometer, the degrees of which differ a little from those of a mercurial thermometer). Then, by experiment,

$$pV=p_0V_0(460{\cdot}6+t)/(460{\cdot}6+32)=p_0V_0\tau/\tau_0, \qquad (4)$$

where τ, τ_0 are the temperatures t and 32° reckoned from the absolute zero, which is $-460{\cdot}6°$ Fahr.;

$$p/G=p_0\tau/G_0\tau_0; \qquad (4a)$$
$$G=p\tau_0G_0/p_0\tau. \qquad (5)$$

If $p_0=2116{\cdot}8$, $G_0=\cdot08075$, $\tau_0=460{\cdot}6+32=492{\cdot}6$, then

$$p/G=53{\cdot}2\tau. \qquad (5a)$$

Or quite generally $p/G=R\tau$ for all gases, if R is a constant varying inversely as the density of the gas at 32° F. For steam R = 85·5.

II. KINEMATICS OF FLUIDS

§ 10. Moving fluids as commonly observed are conveniently classified thus:

(1) *Streams* are moving masses of indefinite length, completely or incompletely bounded laterally by solid boundaries. When the solid boundaries are complete, the flow is said to take place in a pipe. When the solid boundary is incomplete and leaves the upper surface of the fluid free, it is termed a stream bed or channel or canal.

(2) A stream bounded laterally by differently moving fluid of the same kind is termed a *current.*

(3) A *jet* is a stream bounded by fluid of a different kind.

(4) An *eddy, vortex* or *whirlpool* is a mass of fluid the particles of which are moving circularly or spirally.

(5) In a stream we may often regard the particles as flowing along definite paths in space. A chain of particles following each other along such a constant path may be termed a fluid filament or elementary stream.

§ 11. *Steady and Unsteady, Uniform and Varying, Motion.*—There are two quite distinct ways of treating hydrodynamical questions. We may either fix attention on a given mass of fluid and consider its changes of position and energy under the action of the stresses to which it is subjected, or we may have regard to a given fixed portion of space, and consider the volume and energy of the fluid entering and leaving that space.

If, in following a given path ab (fig. 4), a mass of water a has a constant velocity, the motion is said to be uniform. The kinetic energy of the mass a remains unchanged. If the velocity varies from point to point of the path, the motion is called varying motion. If at a given point a in space, the particles of water always arrive with the same velocity and in the same direction, during any given time, then the motion is termed steady motion. On the contrary, if at the point a the velocity or direction varies from moment to moment the motion is termed unsteady. A river which excavates its own bed is in unsteady motion so long as the slope and form of the bed is changing. It, however, tends always towards a condition in which the bed ceases to change, and it is then said to have reached a condition of permanent regime. No river probably is in absolutely permanent regime, except perhaps in rocky channels. In other cases the bed is scoured more or less during the rise of a flood, and silted again during the subsidence of the flood. But while many streams of a torrential character change the condition of their bed often and to a large extent, in others the changes are comparatively small and not easily observed.

FIG. 4.

As a stream approaches a condition of steady motion, its regime becomes permanent. Hence steady motion and permanent regime are sometimes used as meaning the same thing. The one, however, is a definite term applicable to the motion of the water, the other a less definite term applicable in strictness only to the condition of the stream bed.

§ 12. *Theoretical Notions on the Motion of Water.*—The actual motion of the particles of water is in most cases very complex. To simplify hydrodynamic problems, simpler modes of motion are assumed, and the results of theory so obtained are compared experimentally with the actual motions.

Motion in Plane Layers.—The simplest kind of motion in a stream is one in which the particles initially situated in any plane cross section of the stream continue to be found in plane cross sections during the subsequent motion. Thus, if the particles in a thin plane layer ab (fig. 5) are found again in a thin plane layer $a'b'$ after any interval of time, the motion is said to be motion in plane layers. In such motion the internal work in deforming the layer may usually be disregarded, and the resistance to the motion is confined to the circumference.

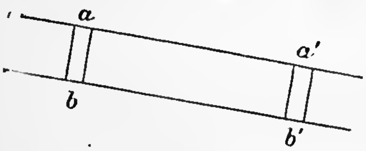

FIG. 5.

Laminar Motion.—In the case of streams having solid boundaries, it is observed that the central parts move faster than the lateral parts. To take account of these differences of velocity, the stream may be conceived to be divided into thin laminae, having cross sections somewhat similar to the solid boundary of the stream, and sliding on each other. The different laminae can then be treated as having differing velocities according to any law either observed or deduced from their mutual friction. A much closer approximation to the real motion of ordinary streams is thus obtained.

Stream Line Motion.—In the preceding hypothesis, all the particles in each lamina have the same velocity at any given cross section of the stream. If this assumption is abandoned, the cross section of the stream must be supposed divided into indefinitely small areas, each representing the section of a fluid filament. Then these filaments may have any law of variation of velocity assigned to them. If the motion is steady motion these fluid filaments (or as they are then termed *stream lines*) will have fixed positions in space.

Periodic Unsteady Motion.—In ordinary streams with rough boundaries, it is observed that at any given point the velocity varies from moment to moment in magnitude and direction, but that the average velocity for a sensible period (say for 5 or 10 minutes) varies very little either in magnitude or velocity. It has hence

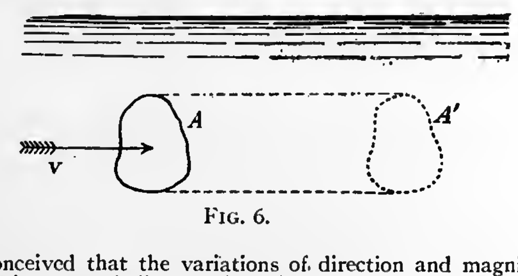

FIG. 6.

been conceived that the variations of direction and magnitude of the velocity are periodic, and that, if for each point of the stream the mean velocity and direction of motion were substituted for the actual more or less varying motions, the motion of the stream might be treated as steady stream line or steady laminar motion.

§ 13. *Volume of Flow.*—Let A (fig. 6) be any ideal plane surface, of area ω, in a stream, normal to the direction of motion, and let V be the velocity of the fluid. Then the volume flowing through the surface A in unit time is

$$Q = \omega V. \qquad (1)$$

Thus, if the motion is rectilinear, all the particles at any instant in the surface A will be found after one second in a similar surface A′, at a distance V, and as each particle is followed by a continuous thread of other particles, the volume of flow is the right prism AA′ having a base ω and length V.

If the direction of motion makes an angle θ with the normal to the surface, the volume of flow is represented by an oblique prism AA′ (fig. 7), and in that case

$$Q = \omega V \cos \theta.$$

If the velocity varies at different points of the surface, let the surface be divided into very small portions, for each of which the velocity may be regarded as constant. If $d\omega$ is the area and v, or $v \cos \theta$, the normal velocity for this element of the surface, the volume of flow is

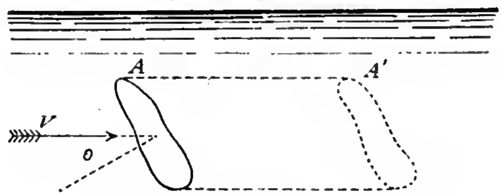

FIG. 7.

$$Q = \int v d\omega, \text{ or } \int v \cos \theta \, d\omega,$$

as the case may be.

§ 14. *Principle of Continuity.*—If we consider any completely bounded fixed space in a moving liquid initially and finally filled continuously with liquid, the inflow must be equal to the outflow. Expressing the inflow with a positive and the outflow with a negative sign, and estimating the volume of flow Q for all the boundaries,

$$\Sigma Q = 0.$$

In general the space will remain filled with fluid if the pressure at every point remains positive. There will be a break of continuity, if at any point the pressure becomes negative, indicating that the stress at that point is tensile. In the case of ordinary water this statement requires modification. Water contains a variable amount of air in solution, often about one-twentieth of its volume. This air is disengaged and breaks the continuity of the liquid, if the pressure falls below a point corresponding to its tension. It is for this reason that pumps will not draw water to the full height due to atmospheric pressure.

Application of the Principle of Continuity to the case of a Stream.—If A_1, A_2 are the areas of two normal cross sections of a stream, and V_1, V_2 are the velocities of the stream at those sections, then from the principle of continuity,

$$V_1 A_1 = V_2 A_2;$$
$$V_1/V_2 = A_2/A_1 \qquad (2)$$

that is, the normal velocities are inversely as the areas of the cross sections. This is true of the mean velocities, if at each section the velocity of the stream varies. In a river of varying slope the velocity varies with the slope. It is easy therefore to see that in parts of large cross section the slope is smaller than in parts of small cross section.

If we conceive a space in a liquid bounded by normal sections at A_1, A_2 and between A_1, A_2 by stream lines (fig. 8), then, as there is no flow across the stream lines,

$$V_1/V_2 = A_2/A_1,$$

as in a stream with rigid boundaries.

In the case of compressible fluids the variation of volume due to the difference of pressure at the two sections must be taken into

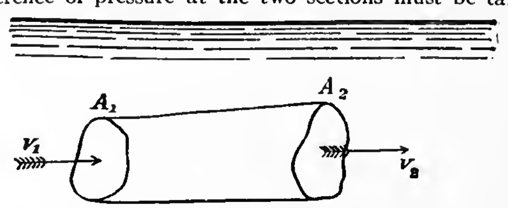

FIG. 8.

account. If the motion is steady the weight of fluid between two cross sections of a stream must remain constant. Hence the weight flowing in must be the same as the weight flowing out. Let p_1, p_2 be the pressures, v_1, v_2 the velocities, G_1, G_2 the weight per cubic foot of fluid, at cross sections of a stream of areas A_1, A_2. The volumes of inflow and outflow are

$$A_1 v_1 \text{ and } A_2 v_2,$$

and, if the weights of these are the same,

$$G_1 A_1 v_1 = G_2 A_2 v_2;$$

and hence, from (5a) § 9, if the temperature is constant,

$$p_1 A_1 v_1 = p_2 A_2 v_2. \qquad (3)$$

§ 15. *Stream Lines.*—The characteristic of a perfect fluid, that is, a fluid free from viscosity, is that the pressure between any two parts into which it is divided by a plane must be normal to the plane. One consequence of this is that the particles can have no rotation impressed upon them, and the motion of such a fluid is irrotational. A stream line is the line, straight or curved, traced by a particle in a current of fluid in irrotational movement. In a steady current

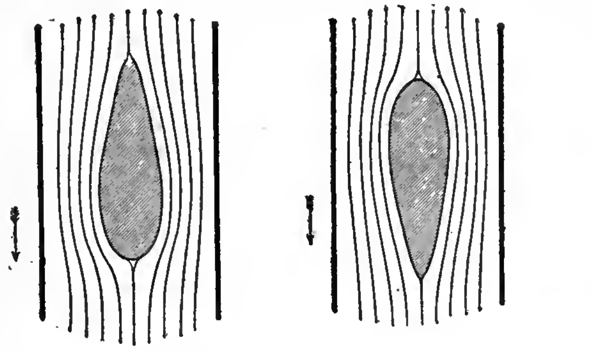

FIG. 9.

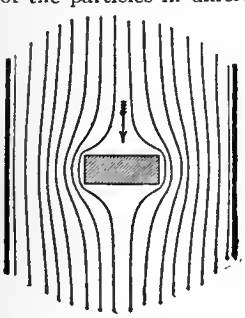
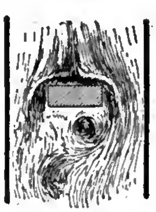
each stream line preserves its figure and position unchanged, and marks the track of a stream of particles forming a fluid filament or elementary stream. A current in steady irrotational movement may be conceived to be divided by insensibly thin partitions following the course of the stream lines into a number of elementary streams. If the positions of these partitions are so adjusted that the volumes of flow in all the elementary streams are equal, they represent to the mind the velocity as well as the direction of motion of the particles in different parts of the current, for the velocities





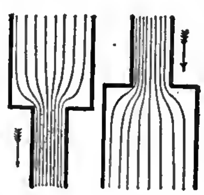


FIG. 10. FIG. 11. FIG. 12.

are inversely proportional to the cross sections of the elementary streams. No actual fluid is devoid of viscosity, and the effect of viscosity is to render the motion of a fluid sinuous, or rotational or eddying under most ordinary conditions. At very low velocities in a tube of moderate size the motion of water may be nearly pure stream line motion. But at some velocity, smaller as the diameter of the tube is greater, the motion suddenly becomes tumultuous. The laws of simple stream line motion have hitherto been investigated theoretically, and from mathematical difficulties have only been determined for certain simple cases. Professor H. S. Hele Shaw has found means of exhibiting stream line motion in a number of very interesting cases experimentally. Generally in these experiments a thin sheet of fluid is caused to flow between two parallel plates of glass. In the earlier experiments streams of very small air bubbles introduced into the water current rendered visible the motions of the water. By the use of a lantern the image of a portion of the current can be shown on a screen or photographed. In later experiments streams of coloured liquid at regular distances were introduced into the sheet and these much more clearly marked out the forms of the stream lines. With a fluid sheet 0·02 in. thick, the stream lines were found to be stable at almost any required velocity. For certain simple cases Professor Hele Shaw has shown that the experimental stream lines of a viscous fluid are so far as can be measured identical with the calculated stream lines of a perfect fluid. Sir G. G. Stokes pointed out that in this case, either from the thinness of the stream between its glass walls, or the slowness of the motion, or the high viscosity of the liquid, or from a combination of all these, the flow is regular, and the effects of inertia disappear, the viscosity dominating everything. Glycerine gives the stream lines very satisfactorily.

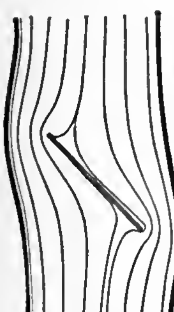

FIG. 13.

FIG. 9 shows the stream lines of a sheet of fluid passing a fairly shipshape body such as a screwshaft strut. The arrow shows the direction of motion of the fluid. Fig. 10 shows the stream lines for a very thin glycerine sheet passing a non-shipshape body, the stream lines being practically perfect. Fig. 11 shows one of the earlier air-bubble experiments with a thicker sheet of water. In this case the stream lines break up behind the obstruction, forming an eddying wake. Fig. 12 shows the stream lines of a fluid passing a sudden contraction or sudden enlargement of a pipe. Lastly, fig. 13 shows the stream lines of a current passing an oblique plane. H. S. Hele Shaw, "Experiments on the Nature of the Surface Resistance in Pipes and on Ships," *Trans. Inst. Naval Arch.* (1897). "Investigation of Stream Line Motion under certain Experimental Conditions," *Trans. Inst. Naval Arch.* (1898); "Stream Line Motion of a Viscous Fluid," *Report of British Association* (1898).

III. PHENOMENA OF THE DISCHARGE OF LIQUIDS FROM ORIFICES AS ASCERTAINABLE BY EXPERIMENTS

§ 16. When a liquid issues vertically from a small orifice, it forms a jet which rises nearly to the level of the free surface of the liquid in the vessel from which it flows. The difference of level h_r (fig. 14) is so small that it may be at once suspected to be due either to air resistance on the surface of the jet or to the viscosity of the liquid or to friction against the sides of the orifice. Neglecting for the moment this small quantity, we may infer, from the elevation of the jet, that each molecule on leaving the orifice possessed the velocity required to lift it against gravity to the height h. From ordinary dynamics, the relation between the velocity and height of projection is given by the equation

$$v=\sqrt{2gh}. \qquad (1)$$

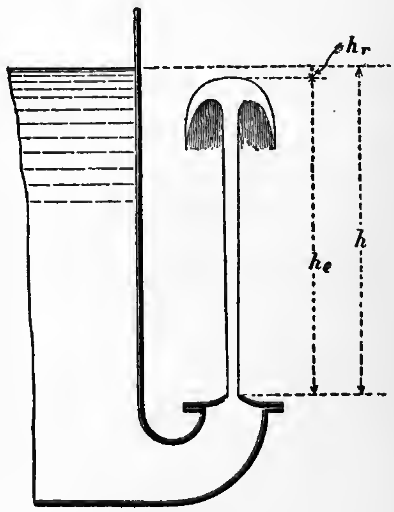

FIG. 14.

As this velocity is nearly reached in the flow from well-formed orifices, it is sometimes called the theoretical velocity of discharge. This relation was first obtained by Torricelli.

If the orifice is of a suitable conoidal form, the water issues in filaments normal to the plane of the orifice. Let ω be the area of the orifice, then the discharge per second must be, from eq. (1),

$$Q=\omega v=\omega\sqrt{2gh} \text{ nearly.} \qquad (2)$$

This is sometimes quite improperly called the theoretical discharge for any kind of orifice. Except for a well-formed conoidal orifice the result is not approximate even, so that if it is supposed to be based on a theory the theory is a false one.

Use of the term Head in Hydraulics.—The term *head* is an old millwright's term, and meant primarily the height through which a mass of water descended in actuating a hydraulic machine. Since the water in fig. 14 descends through a height h to the orifice, we may say there are h ft. of head above the orifice. Still more generally any mass of liquid h ft. above a horizontal plane may be said to have h ft. of elevation head relatively to that datum plane. Further, since the pressure p at the orifice which produces outflow is connected with h by the relation $p/G=h$, the quantity p/G may be termed the pressure head at the orifice. Lastly, the velocity v is connected with h by the relation $v^2/2g=h$, so that $v^2/2g$ may be termed the head due to the velocity v.

§ 17. *Coefficients of Velocity and Resistance.*—As the actual velocity of discharge differs from $\sqrt{2gh}$ by a small quantity, let the actual velocity

$$=v_a=c_v\sqrt{2gh}, \qquad (3)$$

where c_v is a coefficient to be determined by experiment, called the *coefficient of velocity*. This coefficient is found to be tolerably constant for different heads with well-formed simple orifices, and it very often has the value 0·97.

The difference between the velocity of discharge and the velocity due to the head may be reckoned in another way. The total height h causing outflow consists of two parts—one part h_e expended effectively in producing the velocity of outflow, another h_r in overcoming the resistances due to viscosity and friction. Let

$$h_r=c_r h_e,$$

where c_r is a coefficient determined by experiment, and called the *coefficient of resistance* of the orifice. It is tolerably constant for different heads with well-formed orifices. Then

$$v_a=\sqrt{2gh_e}=\sqrt{\{2gh/(1+c_r)\}}. \qquad (4)$$

The relation between c_v and c_r for any orifice is easily found:—

$$v_a = c_v\sqrt{2gh} = \sqrt{\{2gh/(1+c_r)\}}$$
$$c_v = \sqrt{\{1/(1+c_r)\}}. \qquad (5)$$
$$c_r = 1/c_v^2 - 1. \qquad (5a)$$

Thus if $c_v = 0{\cdot}97$, then $c_r = 0{\cdot}0628$. That is, for such an orifice about $6\frac{1}{4}$% of the head is expended in overcoming frictional resistances to flow.

Coefficient of Contraction—Sharp-edged Orifices in Plane Surfaces.—When a jet issues from an aperture in a vessel, it may either spring

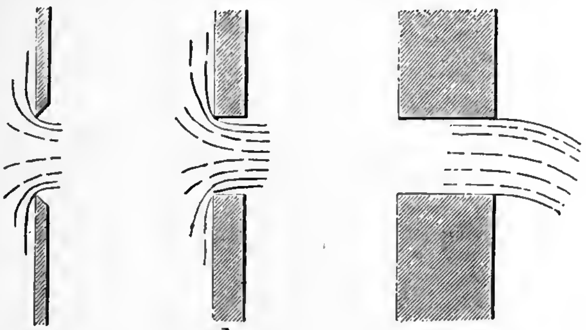

FIG. 15.

clear from the inner edge of the orifice as at *a* or *b* (fig. 15), or it may adhere to the sides of the orifice as at *c*. The former condition will be found if the orifice is bevelled outwards as at *a*, so as to be sharp edged, and it will also occur generally for a prismatic aperture like *b*, provided the thickness of the plate in which the aperture is formed is less than the diameter of the jet. But if the thickness is greater the condition shown at *c* will occur.

When the discharge occurs as at *a* or *b*, the filaments converging towards the orifice continue to converge beyond it, so that the section of the jet where the filaments have become parallel is smaller than the section of the orifice. The inertia of the filaments opposes sudden change of direction of motion at the edge of the orifice, and the convergence continues for a distance of about half the diameter of the orifice beyond it. Let ω be the area of the orifice, and $c_c\omega$ the area of the jet at the point where convergence ceases; then c_c is a coefficient to be determined experimentally for each kind of orifice, called the *coefficient of contraction*. When the orifice is a sharp-edged orifice in a plane surface, the value of c_c is on the average $0{\cdot}64$, or the section of the jet is very nearly five-eighths of the area of the orifice.

Coefficient of Discharge.—In applying the general formula $Q = \omega v$ to a stream, it is assumed that the filaments have a common velocity v normal to the section ω. But if the jet contracts, it is at the contracted section of the jet that the direction of motion is normal to a transverse section of the jet. Hence the actual discharge when contraction occurs is

$$Q_a = c_v v \times c_c\omega = c_c c_v \omega\sqrt{(2gh)},$$

or simply, if $c = c_v c_c$,

$$Q_a = c\omega\sqrt{(2gh)},$$

where c is called the *coefficient of discharge*. Thus for a sharp-edged plane orifice $c = 0{\cdot}97 \times 0{\cdot}64 = 0{\cdot}62$.

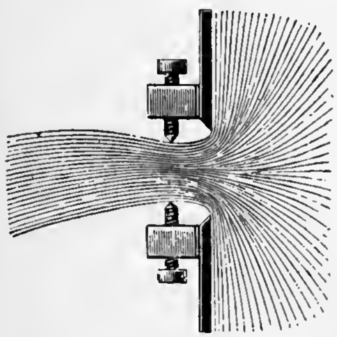

FIG. 16.

§ 18. *Experimental Determination of c_v, c_c, and c.*—The coefficient of contraction c_c is directly determined by measuring the dimensions of the jet. For this purpose fixed screws of fine pitch (fig. 16) are convenient. These are set to touch the jet, and then the distance between them can be measured at leisure.

The coefficient of velocity is determined directly by measuring the parabolic path of a horizontal jet.

Let OX, OY (fig. 17) be horizontal and vertical axes, the origin being at the orifice. Let h be the head, and x, y the coordinates of a point A on the parabolic path of the jet. If v_a is the velocity at the orifice, and t the time in which a particle moves from O to A, then

$$x = v_a t;\ y = \tfrac{1}{2}gt^2.$$

Eliminating t,

$$v_a = \sqrt{(gx^2/2y)}.$$

Then

$$c_v = v_a/\sqrt{(2gh)} = \sqrt{(x^2/4yh)}.$$

In the case of large orifices such as weirs, the velocity can be directly determined by using a Pitot tube (§ 144).

The coefficient of discharge, which for practical purposes is the most important of the three coefficients, is best determined by tank measurement of the flow from the given orifice in a suitable time. If Q is the discharge measured in the tank per second, then

$$c = Q/\omega\sqrt{(2gh)}.$$

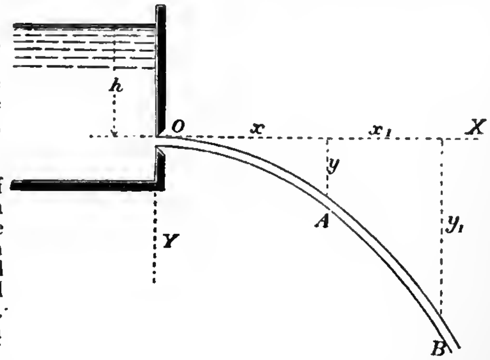

FIG. 17.

Measurements of this kind though simple in principle are not free from some practical difficulties, and require much care. In fig. 18 is shown an arrangement of measuring tank. The orifice is fixed in the wall of the cistern A and discharges either into the waste channel BB, or into the measuring tank. There is a short trough on rollers C which when run under the jet directs the discharge into the tank, and when run back again allows the discharge to drop into the waste channel. D is a stilling screen to prevent agitation of the surface at the measuring point, E, and F is a discharge valve for emptying the measuring tank. The rise of level in the tank, the time of the flow and the head over the orifice at that time must be exactly observed.

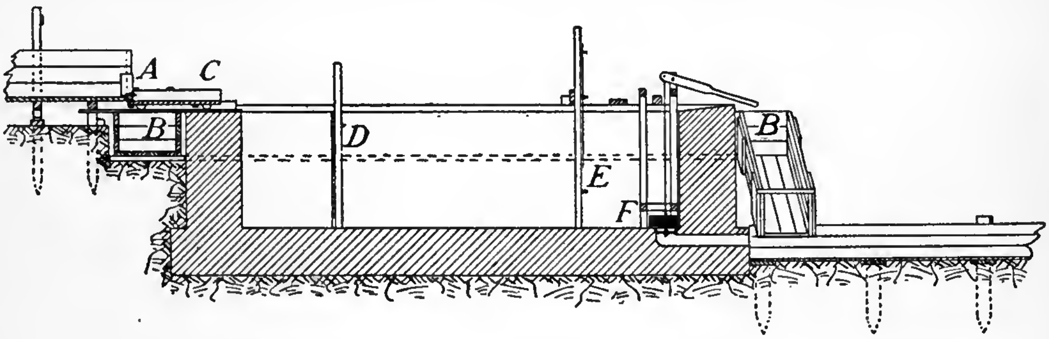

FIG. 18.

For well made sharp-edged orifices, small relatively to the water surface in the supply reservoir, the coefficients under different conditions of head are pretty exactly known. Suppose the same quantity of water is made to flow in succession through such an orifice and through another orifice of which the coefficient is required, and when the rate of flow is constant the heads over each orifice are noted. Let h_1, h_2 be the heads, ω_1, ω_2 the areas of the orifices, c_1, c_2 the coefficients. Then since the flow through each orifice is the same

$$Q = c_1\omega_1\sqrt{(2gh_1)} = c_2\omega_2\sqrt{(2gh_2)}.$$
$$c_2 = c_1(\omega_1/\omega_2)\sqrt{(h_1/h_2)}.$$

§ 19. *Coefficients for Bellmouths and Bellmouthed Orifices.*—If an orifice is furnished with a mouthpiece exactly of the form of the

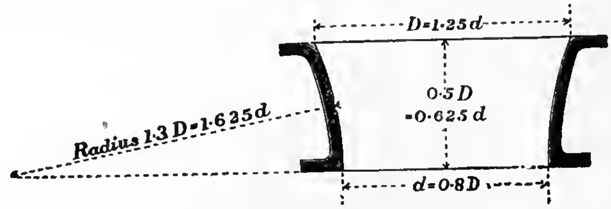

FIG. 19.

contracted vein, then the whole of the contraction occurs within the mouthpiece, and if the area of the orifice is measured at the smaller end, c_c must be put $= 1$. It is often desirable to bellmouth the ends of pipes, to avoid the loss of head which occurs if this is not done; and such a bellmouth may also have the form of the contracted jet. Fig. 19 shows the proportions of such a bellmouth or bellmouthed orifice, which approximates to the form of the contracted jet sufficiently for any practical purpose.

For such an orifice L. J. Weisbach found the following values of the coefficients with different heads.

Head over orifice, in ft. $=h$	·66	1·64	11·48	55·77	337·93
Coefficient of velocity $=c_v$	·959	·967	·975	·994	·994
Coefficient of resistance $=c_r$	·087	·069	·052	·012	·012

As there is no contraction after the jet issues from the orifice, $c_c=1$, $c=c_v$; and therefore

$$Q=c_v\omega\sqrt{(2gh)}=\omega\sqrt{\{2gh/(1+c_r)\}}.$$

§ 20. *Coefficients for Sharp-edged or virtually Sharp-edged Orifices.*—There are a very large number of measurements of discharge from sharp-edged orifices under different conditions of head. An account of these and a very careful tabulation of the average values of the coefficients will be found in the *Hydraulics* of the late Hamilton Smith (Wiley & Sons, New York, 1886). The following short table abstracted from a larger one will give a fair notion of how the coefficient varies according to the most trustworthy of the experiments.

Coefficient of Discharge for Vertical Circular Orifices, Sharp-edged, with free Discharge into the Air. $Q=c\omega\sqrt{(2gh)}$.

Head measured to Centre of Orifice.	Diameters of Orifice.						
	·02	·04	·10	·20	·40	·60	1·0
	Values of *C*.						
0·3	..	..	·621	..	..	..	..
0·4	..	·637	·618	..	..	..	..
0·6	·655	·630	·613	·601	·596	·588	..
0·8	·648	·626	·610	·601	·597	·594	·583
1·0	·644	·623	·608	·600	·598	·595	·591
2·0	·632	·614	·604	·599	·599	·597	·595
4·0	·623	·609	·602	·599	·598	·597	·596
8·0	·614	·605	·600	·598	·597	·596	·596
20·0	·601	·599	·596	·596	·596	·596	·594

At the same time it must be observed that differences of sharpness in the edge of the orifice and some other circumstances affect the results, so that the values found by different careful experimenters are not a little discrepant. When exact measurement of flow has to be made by a sharp-edged orifice it is desirable that the coefficient for the particular orifice should be directly determined.

The following results were obtained by Dr H. T. Bovey in the laboratory of McGill University.

Coefficient of Discharge for Sharp-edged Orifices.

Head in ft.	Form of Orifice.							
	Circular.	Square.		Rectangular Ratio of Sides 4:1.		Rectangular Ratio of Sides 16:1.		Triangular.
		Sides vertical.	Diagonal vertical.	Long Sides vertical.	Long Sides horizontal.	Long Sides vertical.	Long Sides horizontal.

The orifice was 0·196 sq. in. area and the reductions were made with $g=32\cdot176$ the value for Montreal. The value of the coefficient appears to increase as (perimeter) / (area) increases. It decreases as the head increases. It decreases a little as the size of the orifice is greater.

Very careful experiments by J. G. Mair (*Proc. Inst. Civ. Eng.* lxxxiv.) on the discharge from circular orifices gave the results shown on top of next column.

The edges of the orifices were got up with scrapers to a sharp square edge. The coefficients generally fall as the head increases and as the diameter increases. Professor W. C. Unwin found that the results agree with the formula

$$c=0\cdot6075+0\cdot0098/\sqrt{h}-0\cdot0037d,$$

where h is in feet and d in inches.

The following table, compiled by J. T. Fanning (*Treatise on Water Supply Engineering*), gives values for rectangular orifices in vertical plane surfaces, the head being measured, not immediately over the orifice, where the surface is depressed, but to the still-water surface at some distance from the orifice. The values were obtained by graphic interpolation, all the most reliable experiments being plotted and curves drawn so as to average the discrepancies.

§ 21. *Orifices with Edges of Sensible Thickness.*—When the edges of the orifice are not bevelled outwards, but have a sensible thickness, the coefficient of discharge is somewhat altered. The following table gives values of the coefficient of discharge for the arrangements of the orifice shown in vertical section at P, Q, R (fig. 20). The plan of all the orifices is shown at S. The planks forming the orifice and sluice were each 2 in. thick, and the orifices were all 24 in. wide. The heads were measured immediately over the orifice. In this case,

$$Q=cb(H-h)\sqrt{\{2g(H+h)/2\}}.$$

§ 22. *Partially Suppressed Contraction.*—Since the contraction of the jet is due to the convergence towards the orifice of the issuing streams, it will be diminished if for any portion of the edge of the orifice the convergence is prevented. Thus, if an internal rim or border is applied to part of the edge of the orifice (fig. 21), the convergence for so much of the edge is suppressed. For such cases G. Bidone found the following empirical formulae applicable:—

Table of Coefficients of Discharge for Rectangular Vertical Orifices in Fig. 20.

For rectangular orifices,

$$c_e = 0{\cdot}62(1+0{\cdot}152n/p);$$

and for circular orifices,

$$c_e = 0{\cdot}62(1+0{\cdot}128n/p);$$

when n is the length of the edge of the orifice over which the border extends, and p is the whole length of edge or perimeter of the orifice. The following are the values of c_e, when the border extends over $\frac{1}{4}$, $\frac{1}{2}$ or $\frac{3}{4}$ of the whole perimeter:—

n/p	c_e Rectangular Orifices.	c_e Circular Orifices.
0·25	0·643	·640
0·50	0·667	·660
0·75	0·691	·680

For larger values of n/p the formulae are not applicable. C. R. Bornemann has shown, however, that these formulae for suppressed contraction are not reliable.

§ 23. *Imperfect Contraction.*—If the sides of the vessel approach near to the edge of the orifice, they interfere with the convergence of the streams to which the contraction is due, and the contraction is then modified. It is generally stated that the influence of the sides begins to be felt if their distance from the edge of the orifice is less than 2·7 times the corresponding width of the orifice. The coefficients of contraction for this case are imperfectly known.

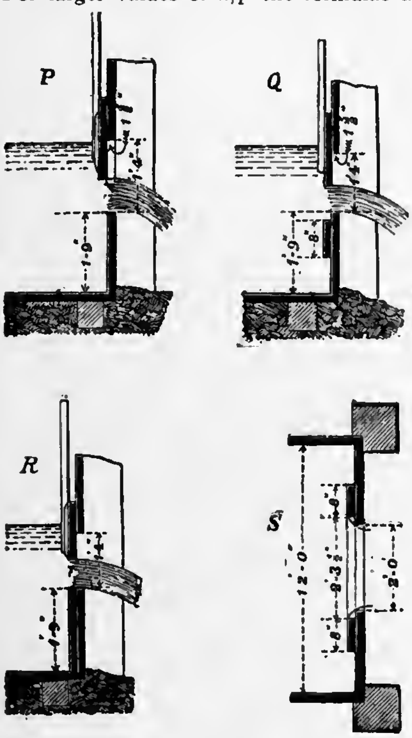

FIG. 20.

FIG. 21.

§ 24. *Orifices Furnished with Channels of Discharge.*—These external borders to an orifice also modify the contraction.

The following coefficients of discharge were obtained with openings 8 in. wide, and small in proportion to the channel of approach (fig. 22, A, B, C).

h_2-h_1 in feet.		h_1 in feet.

§ 25. *Inversion of the Jet.*—When a jet issues from a horizontal orifice, or is of small size compared with the head, it presents no marked peculiarity of form. But if the orifice is in a vertical surface, and if its dimensions are not small compared with the head,

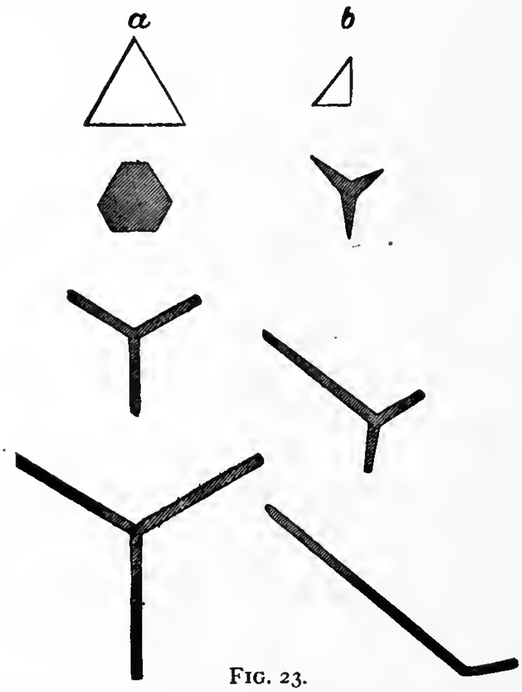

FIG. 23.

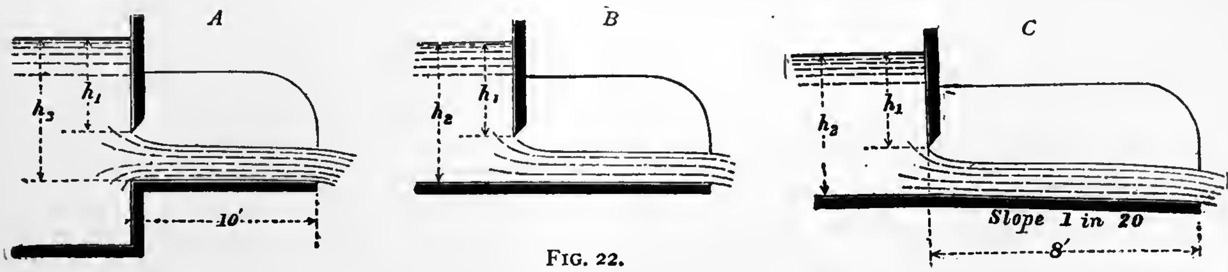

FIG. 22.

it undergoes a series of singular changes of form after leaving the orifice. These were first investigated by G. Bidone (1781–1839); subsequently H. G. Magnus (1802–1870) measured jets from different orifices; and later Lord Rayleigh (*Proc. Roy. Soc.* xxix. 71) investigated them anew.

Fig. 23 shows some forms, the upper figure giving the shape of the orifices, and the others sections of the jet. The jet first contracts as described above, in consequence of the convergence of the fluid streams within the vessel, retaining, however, a form similar to that of the orifice. Afterwards it expands into sheets in planes perpendicular to the sides of the orifice. Thus the jet from a triangular orifice expands into three sheets, in planes bisecting at right angles the three sides of the triangle. Generally a jet from an orifice, in the form of a regular polygon of n sides, forms n sheets in planes perpendicular to the sides of the polygon.

Bidone explains this by reference to the simpler case of meeting streams. If two equal streams having the same axis, but moving in opposite directions, meet, they spread out into a thin disk normal to the common axis of the streams. If the directions of two streams intersect obliquely they spread into a symmetrical sheet perpendicular to the plane of the streams.

Let a_1, a_2 (fig. 24) be two points in an orifice at depths h_1, h_2 from the free surface. The filaments issuing at a_1, a_2 will have the different velocities $\sqrt{2gh_1}$ and $\sqrt{2gh_2}$. Consequently they will tend to describe parabolic paths a_1cb_1 and a_2cb_2 of different horizontal range, and intersecting in the point c. But since two filaments cannot simultaneously flow through the same point, they must exercise mutual pressure, and will be deflected out of the paths they tend to describe. It is this mutual pressure which causes the expansion of the jet into sheets.

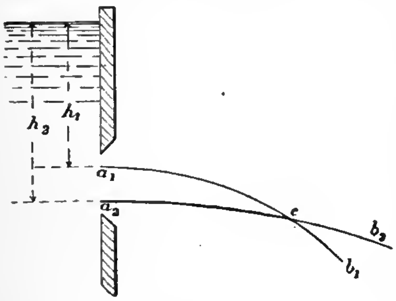

FIG. 24.

Lord Rayleigh pointed out that, when the orifices are small and the head is not great, the expansion of the sheets in directions perpendicular to the direction of flow reaches a limit. Sections taken at greater distance from the orifice show a contraction of the sheets until a compact form is reached similar to that at the first contraction. Beyond this point, if the jet retains its coherence, sheets are thrown out again, but in directions bisecting the angles between the previous sheets. Lord Rayleigh accepts an explanation of this contraction first suggested by H. Buff (1805–1878), namely, that it is due to surface tension.

§ 26. *Influence of Temperature on Discharge of Orifices.*—Professor W. C. Unwin found (*Phil. Mag.*, October 1878, p. 281) that for sharp-edged orifices temperature has a very small influence on the discharge. For an orifice 1 cm. in diameter with heads of about 1 to 1½ ft. the coefficients were:—

Temperature F.	C.
205°	·594
62°	·598

For a conoidal or bell-mouthed orifice 1 cm. diameter the effect of temperature was greater:—

Temperature F.	C.
190°	0·987
130°	0·974
60°	0·942

an increase in velocity of discharge of 4% when the temperature increased 130°.

J. G. Mair repeated these experiments on a much larger scale (*Proc. Inst. Civ. Eng.* lxxxiv.). For a sharp-edged orifice 2½ in. diameter, with a head of 1·75 ft., the coefficient was 0·604 at 57° and 0·607 at 179° F., a very small difference. With a conoidal orifice the coefficient was 0·961 at 55° and 0·981 at 170° F. The corresponding coefficients of resistance are 0·0828 and 0·0391, showing that the resistance decreases to about half at the higher temperature.

§ 27. *Fire Hose Nozzles.*—Experiments have been made by J. R. Freeman on the coefficient of discharge from smooth cone nozzles used for fire purposes. The coefficient was found to be 0·983 for ¾-in. nozzle; 0·982 for ⅞ in.; 0·972 for 1 in.; 0·976 for 1⅛ in.; and 0·971 for 1¼ in. The nozzles were fixed on a taper play-pipe, and the coefficient includes the resistance of this pipe (*Amer. Soc. Civ. Eng.* xxi., 1889). Other forms of nozzle were tried such as ring nozzles for which the coefficient was smaller.

IV. THEORY OF THE STEADY MOTION OF FLUIDS.

§ 28. The general equation of the steady motion of a fluid given under Hydrodynamics furnishes immediately three results as to the distribution of pressure in a stream which may here be assumed.

(*a*) If the motion is rectilinear and uniform, the variation of pressure is the same as in a fluid at rest. In a stream flowing in an open channel, for instance, when the effect of eddies produced by the roughness of the sides is neglected, the pressure at each point is simply the hydrostatic pressure due to the depth below the free surface.

(*b*) If the velocity of the fluid is very small, the distribution of pressure is approximately the same as in a fluid at rest.

(*c*) If the fluid molecules take precisely the accelerations which they would have if independent and submitted only to the external forces, the pressure is uniform. Thus in a jet falling freely in the air the pressure throughout any cross section is uniform and equal to the atmospheric pressure.

(*d*) In any bounded plane section traversed normally by streams which are rectilinear for a certain distance on either side of the section, the distribution of pressure is the same as in a fluid at rest.

DISTRIBUTION OF ENERGY IN INCOMPRESSIBLE FLUIDS.

§ 29. *Application of the Principle of the Conservation of Energy to Cases of Stream Line Motion.*—The external and internal work done on a mass is equal to the change of kinetic energy produced. In many hydraulic questions this principle is difficult to apply, because from the complicated nature of the motion produced it is difficult to estimate the total kinetic energy generated, and because in some cases the internal work done in overcoming frictional or viscous resistances cannot be ascertained; but in the case of stream line motion it furnishes a simple and important result known as Bernoulli's theorem.

Let AB (fig. 25) be any one elementary stream, in a steadily moving fluid mass. Then, from the steadiness of the motion, AB is a fixed path in space through which a stream of fluid is constantly flowing. Let OO be the free surface and XX any horizontal datum line. Let

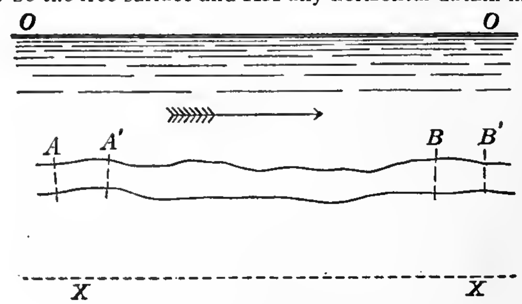

FIG. 25.

ω be the area of a normal cross section, v the velocity, p the intensity of pressure, and z the elevation above XX, of the elementary stream AB at A, and ω_1, p_1, v_1, z_1 the same quantities at B. Suppose that in a short time t the mass of fluid initially occupying AB comes to A′B′. Then AA′, BB′ are equal to vt, v_1t, and the volumes of fluid AA′, BB′ are the equal inflow and outflow $= Qt = \omega vt = \omega_1 v_1 t$, in the given time. If we suppose the filament AB surrounded by other filaments moving with not very different velocities, the frictional or viscous resistance on its surface will be small enough to be neglected, and if the fluid is incompressible no internal work is done in change of volume. Then the work done by external forces will be equal to the kinetic energy produced in the time considered.

The normal pressures on the surface of the mass (excluding the ends A, B) are at each point normal to the direction of motion, and do no work. Hence the only external forces to be reckoned are gravity and the pressures on the ends of the stream.

The work of gravity when AB falls to A′B′ is the same as that of transferring AA′ to BB′; that is, $GQt\,(z-z_1)$. The work of the pressures on the ends, reckoning that at B negative, because it is opposite to the direction of motion, is $(p\omega \times vt) - (p_1\omega_1 \times v_1 t) = Qt(p-p_1)$. The change of kinetic energy in the time t is the difference of the kinetic energy originally possessed by AA′ and that finally acquired by BB′, for in the intermediate part A′B there is no change of kinetic energy, in consequence of the steadiness of the motion. But the mass of AA′ and BB′ is GQt/g, and the change of kinetic energy is therefore $(GQt/g)\,(v_1^2/2 - v^2/2)$. Equating this to the work done on the mass AB,

$$GQt(z-z_1)+Qt(p-p_1)=(GQt/g)\,(v_1^2/2-v^2/2).$$

Dividing by GQt and rearranging the terms,

$$v^2/2g+p/G+z=v_1^2/2g+p_1/G+z_1; \qquad (1)$$

or, as A and B are any two points,

$$v^2/2g+p/G+z=\text{constant}=H. \qquad (2)$$

Now $v^2/2g$ is the head due to the velocity v, p/G is the head equivalent to the pressure, and z is the elevation above the datum (see § 16). Hence the terms on the left are the total head due to velocity, pressure, and elevation at a given cross section of the filament, z is easily seen to be the work in foot-pounds which would be done by 1 lb of fluid falling to the datum line, and similarly p/G and $v^2/2g$ are the quantities of work which would be done by 1 lb of fluid due to the pressure p and velocity v. The expression on the left of the equation is, therefore, the total energy of the stream at the section considered, per lb of fluid, estimated with reference to the datum line XX. Hence we see that in stream line motion, under the restrictions named above, the total energy per lb of fluid is uniformly distributed along the stream line. If the free surface of the fluid OO is taken as the datum, and $-h$, $-h_1$ are the depths of A and B measured down from the free surface, the equation takes the form

$$v^2/2g+p/G-h=v_1^2/2g+p_1/G-h_1; \qquad (3)$$

or generally

$$v^2/2g+p/G-h=\text{constant}. \qquad (3a)$$

§ 30. *Second Form of the Theorem of Bernoulli.*—Suppose at the two sections A, B (fig. 26) of an elementary stream small vertical pipes are introduced, which may be termed pressure columns

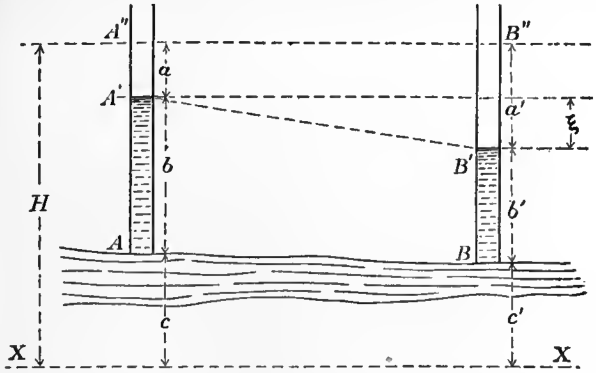

FIG. 26.

(§ 8), having their lower ends accurately parallel to the direction of flow. In such tubes the water will rise to heights corresponding to the pressures at A and B. Hence $b=p/G$, and $b'=p_1/G$. Consequently the tops of the pressure columns A′ and B′ will be at total heights $b+c=p/G+z$ and $b'+c'=p_1/G+z_1$ above the datum line XX. The difference of level of the pressure column tops, or the fall of free surface level between A and B, is therefore

$$\xi=(p-p_1)/G+(z-z_1);$$

and this by equation (1), § 29 is $(v_1^2-v^2)/2g$. That is, the fall of free surface level between two sections is equal to the difference of the heights due to the velocities at the sections. The line A′B′ is sometimes called the line of hydraulic gradient, though this term is also used in cases where friction needs to be taken into account. It is the line the height of which above datum is the sum of the elevation and pressure head at that point, and it falls below a horizontal line A″B″ drawn at H ft. above XX by the quantities $a=v^2/2g$ and $a'=v_1^2/2g$, when friction is absent.

§ 31. *Illustrations of the Theorem of Bernoulli.* In a lecture to the mechanical section of the British Association in 1875, W. Froude gave some experimental illustrations of the principle of Bernoulli. He remarked that it was a common but erroneous impression that a fluid exercises in a contracting pipe A (fig. 27) an excess of pressure against the entire converging surface which it meets, and that, conversely, as it enters an enlargement B, a relief of pressure is experienced by the entire diverging surface of the pipe. Further it is commonly assumed that when passing through a contraction C, there is in the narrow neck an excess of pressure due to the squeezing together of the liquid at that point. These impressions are in no respect correct; the pressure is smaller as the section of the pipe is smaller and conversely.

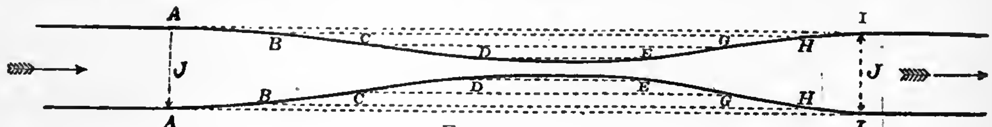

FIG. 30.

Fig. 28 shows a pipe so formed that a contraction is followed by an enlargement, and fig. 29 one in which an enlargement is followed by a contraction. The vertical pressure columns show the decrease of pressure at the contraction and increase of pressure at the enlargement. The line *abc* in both figures shows the variation of free surface level, supposing the pipe frictionless. In actual pipes, however, work is expended in friction against the pipe; the total head diminishes in proceeding along the pipe, and the free surface level is a line such as ab_1c_1, falling below *abc*.

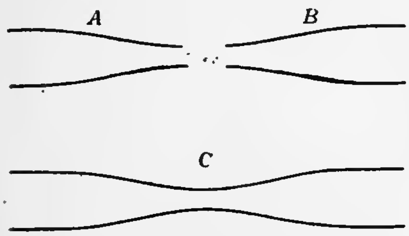

FIG. 27.

Froude further pointed out that, if a pipe contracts and enlarges again to the same size, the resultant pressure on the converging part exactly balances the resultant pressure on the diverging part so that there is no tendency to move the pipe bodily when water flows through it. Thus the conical part AB (fig. 30) presents the same projected surface as HI, and the pressures parallel to the axis of the pipe, normal to these projected surfaces, balance each other. Similarly the pressures on BC, CD balance those on GH, EG. In the same way, in any combination of enlargements and contractions, a balance of pressures, due to the flow of liquid parallel to the

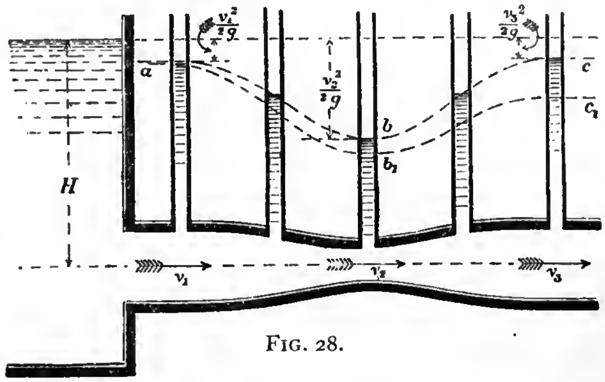

FIG. 28.

axis of the pipe, will be found, provided the sectional area and direction of the ends are the same.

The following experiment is interesting. Two cisterns provided with converging pipes were placed so that the jet from one was exactly opposite the entrance to the other. The cisterns being filled

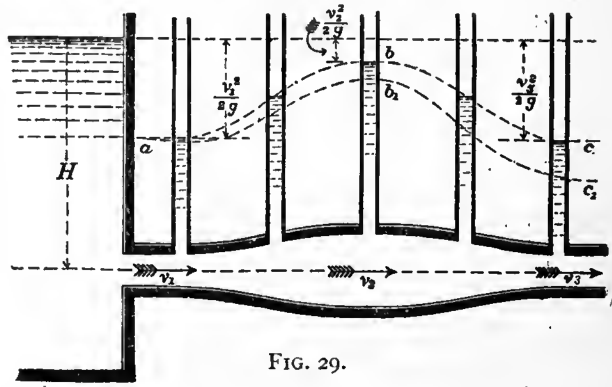

FIG. 29.

very nearly to the same level, the jet from the left-hand cistern A entered the right-hand cistern B (fig. 31), shooting across the free space between them without any waste, except that due to indirectness of aim and want of exact correspondence in the form of the orifices. In the actual experiment there was 18 in. of head in the right and $20\frac{1}{2}$ in. of head in the left-hand cistern, so that about $2\frac{1}{2}$ in. were wasted in friction. It will be seen that in the open space between the orifices there was no pressure, except the atmospheric pressure acting uniformly throughout the system.

§ 32. *Venturi Meter.*—An ingenious application of the variation of pressure and velocity in a converging and diverging pipe has been

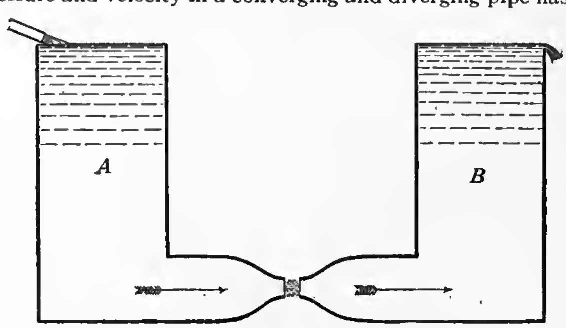

FIG. 31.

made by Clemens Herschel in the construction of what he terms a Venturi Meter for measuring the flow in water mains. Suppose that, as in fig. 32, a contraction is made in a water main, the change of section being gradual to avoid the production of eddies. The ratio ρ

of the cross sections at A and B, that is at inlet and throat, is in actual meters 5 to 1 to 20 to 1, and is very carefully determined by the maker of the meter. Then, if v and u are the velocities at A and B, $u=\rho v$. Let pressure pipes be introduced at A, B and C,

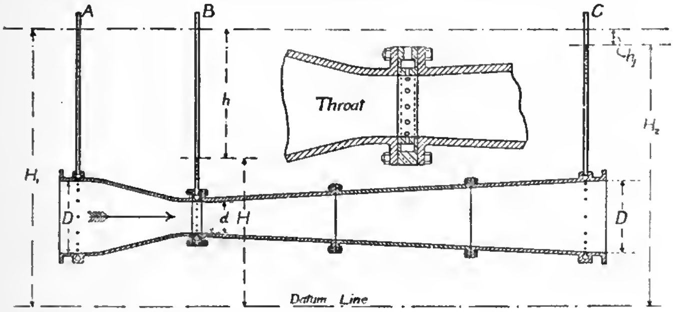

FIG. 32.

and let H_1, H, H_2 be the pressure heads at those points. Since the velocity at B is greater than at A the pressure will be less. Neglecting friction

$$H_1+v^2/2g=H+u^2/2g,$$
$$H_1-H=(u^2-v^2)/2g=(\rho^2-1)v^2/2g.$$

Let $h=H_1-H$ be termed the Venturi head, then

$$u=\sqrt{\{\rho^2.2gh/(\rho^2-1)\}},$$

from which the velocity through the throat and the discharge of the main can be calculated if the areas at A and B are known and h observed. Thus if the diameters at A and B are 4 and 12 in., the areas are 12·57 and 113·1 sq. in., and $\rho=9$,

$$u=\sqrt{81/80}\sqrt{(2gh)}=1{\cdot}007\sqrt{(2gh)}.$$

If the observed Venturi head is 12 ft.,

$$u=28 \text{ ft. per sec.,}$$

and the discharge of the main is

$$28\times12{\cdot}57=351 \text{ cub. ft. per sec.}$$

Hence by a simple observation of pressure difference, the flow in the main at any moment can be determined. Notice that the pressure height at C will be the same as at A except for a small loss h_f due to friction and eddying between A and B. To get the pressure at the throat very exactly Herschel surrounds it by an annular passage communicating with the throat by several small holes, sometimes formed in vulcanite to prevent corrosion. Though constructed to prevent eddying as much as possible there is some eddy loss. The main effect of this is to cause a loss of head between A and C which may vary from a fraction of a foot to perhaps 5 ft. at the highest velocities at which a meter can be used. The eddying also affects a little the Venturi head h. Consequently an experimental coefficient must be determined for each meter by tank measurement. The range of this coefficient is, however, surprisingly small. If to allow for friction, $u=k\sqrt{\{\rho^2/(\rho^2-1)\}}\sqrt{(2gh)}$, then Herschel found values of k from 0·97 to 1·0 for throat velocities varying from 8 to 28 ft. per sec. The meter is extremely convenient. At Staines reservoirs there are two meters of this type on mains 94 in. in diameter. Herschel contrived a recording arrangement which records the variation of flow from hour to hour and also the total flow in any given time. In Great Britain the meter is constructed by G. Kent, who has made improvements in the recording arrangement.

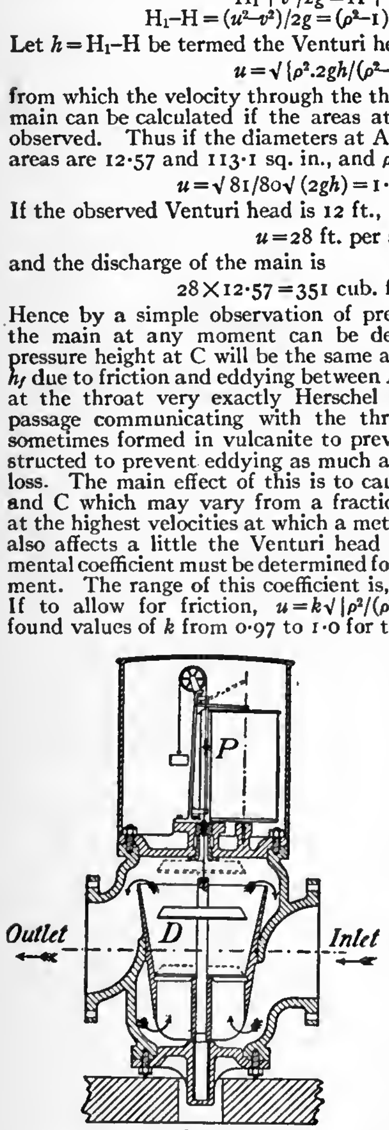

FIG. 33.

In the Deacon Waste Water Meter (fig. 33) a different principle is used. A disk D, partly counterbalanced by a weight, is suspended in the water flowing through the main in a conical chamber. The unbalanced weight of the disk is supported by the impact of the water. If the discharge of the main increases the disk rises, but as it rises its position in the chamber is such that in consequence of the larger area the velocity is less. It finds, therefore, a new position of equilibrium. A pencil P records on a drum moved by clockwork the position of the disk, and from this the variation of flow is inferred.

§ 33. *Pressure, Velocity and Energy in Different Stream Lines.*—The equation of Bernoulli gives the variation of pressure and velocity from point to point along a stream line, and shows that the total energy of the flow across any two sections is the same. Two other directions may be defined, one normal to the stream line and in the plane containing its radius of curvature at any point, the other normal to the stream line and the radius of curvature. For the problems most practically useful it will be sufficient to consider the stream lines as parallel to a vertical or horizontal plane. If the motion is in a vertical plane, the action of gravity must be taken into the reckoning; if the motion is in a horizontal plane, the terms expressing variation of elevation of the filament will disappear.[1]

Let AB, CD (fig. 34) be two consecutive stream lines, at present assumed to be in a vertical plane, and PQ a normal to these lines

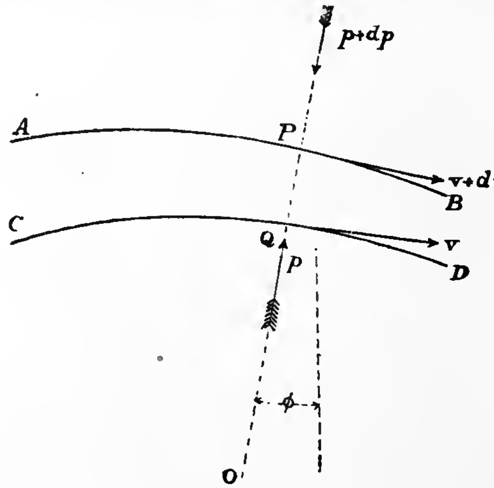

FIG. 34.

making an angle ϕ with the vertical. Let P, Q be two particles moving along these lines at a distance $PQ=ds$, and let z be the height of Q above the horizontal plane with reference to which the energy is measured, v its velocity, and p its pressure. Then, if H is the total energy at Q per unit of weight of fluid,

$$H=z+p/G+v^2/2g.$$

Differentiating, we get

$$dH=dz+dp/G+vdv/g, \quad (1)$$

for the increment of energy between Q and P. But

$$dz=PQ\cos\phi=ds\cos\phi;$$
$$\therefore dH=dp/G+vdv/g+ds\cos\phi, \quad (1a)$$

where the last term disappears if the motion is in a horizontal plane.

Now imagine a small cylinder of section ω described round PQ as an axis. This will be in equilibrium under the action of its centrifugal force, its weight and the pressure on its ends. But its volume is ωds and its weight $G\omega ds$. Hence, taking the components of the forces parallel to PQ—

$$\omega dp=Gv^2\omega ds/g\rho-G\omega\cos\phi ds,$$

where ρ is the radius of curvature of the stream line at Q. Consequently, introducing these values in (1),

$$dH=v^2ds/g\rho+vdv/g=(v/g)(v/\rho+dv/ds)ds. \quad (2)$$

CURRENTS

§ 34. *Rectilinear Current.*—Suppose the motion is in parallel straight stream lines (fig. 35) in a vertical plane. Then ρ is infinite, and from eq. (2), § 33,

$$dH=vdv/g.$$

Comparing this with (1) we see that

$$dz+dp/G=0;$$
$$\therefore z+p/G=\text{constant}; \quad (3)$$

or the pressure varies hydrostatically as in a fluid at rest. For two stream lines in a horizontal plane, z is constant, and therefore p is constant.

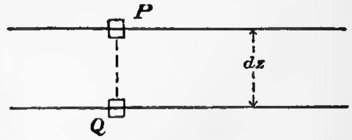

FIG. 35.

Radiating Current.—Suppose water flowing radially between horizontal parallel planes, at a distance apart $=\delta$. Conceive two cylindrical sections of the current at radii r_1 and r_2, where the velocities are v_1 and v_2, and the pressures p_1 and p_2. Since the flow across each cylindrical section of the current is the same,

$$Q=2\pi r_1\delta v_1=2\pi r_2\delta v_2$$
$$r_1v_1=r_2v_2$$
$$r_1/r_2=v_2/v_1. \quad (4)$$

[1] The following theorem is taken from a paper by J. H. Cotterill, "On the Distribution of Energy in a Mass of Fluid in Steady Motion," *Phil. Mag.*, February 1876.

The velocity would be infinite at radius 0, if the current could be conceived to extend to the axis. Now, if the motion is steady,

$$H = p_1/G + v_1^2/2g = p_2/G + v_2^2/2g;$$
$$= p_2/G + r_1^2v_1^2/r_2^2 2g;$$
$$(p_2 - p_1)/G = v_1^2(1 - r_1^2/r_2^2)/2g; \qquad (5)$$
$$p_2/G = H - r_1^2v_1^2/r_2^2 2g. \qquad (6)$$

Hence the pressure increases from the interior outwards, in a way indicated by the pressure columns in fig. 36, the curve through the free surfaces of the pressure columns being, in a radial section, the quasi-hyperbola of the form $xy^2 = c^3$. This curve is asymptotic to a horizontal line, H ft. above the line from which the pressures are measured, and to the axis of the current.

Free Circular Vortex.—A free circular vortex is a revolving mass of water, in which the stream lines are concentric circles, and in which the total head for each stream line is the same. Hence, if by any slow radial motion portions of the water strayed from one stream line to another, they would take freely the velocities propei to their new positions under the action of the existing fluid pressures only.

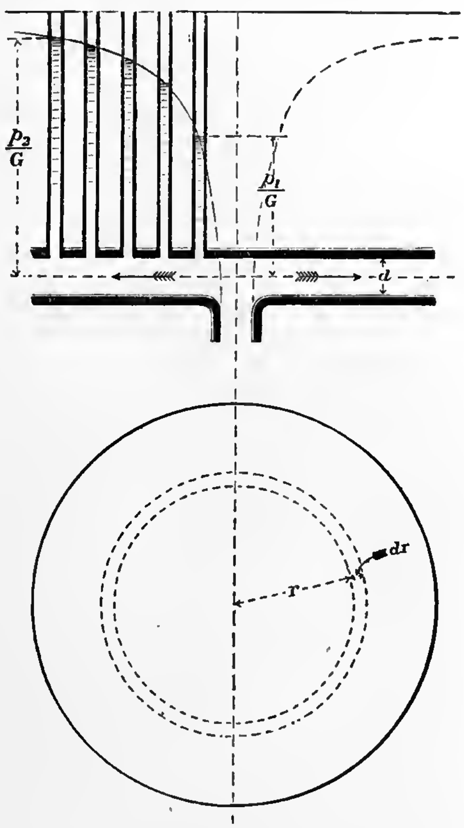

Fig. 36.

For such a current, the motion being horizontal, we have for all the circular elementary streams

$$H = p/G + v^2/2g = \text{constant};$$
$$\therefore dH = dp/G + vdv/g = 0. \qquad (7)$$

Consider two stream lines at radii r and $r+dr$ (fig. 36). Then in (2), § 33, $\rho = r$ and $ds = dr$,

$$v^2dr/gr + vdv/g = 0,$$
$$dv/v = -dr/r,$$
$$v \propto 1/r, \qquad (8)$$

precisely as in a radiating current; and hence the distribution of pressure is the same, and formulae 5 and 6 are applicable to this case.

Free Spiral Vortex.—As in a radiating and circular current the equations of motion are the same, they will also apply to a vortex in which the motion is compounded of these motions in any proportions, provided the radial component of the motion varies inversely as the radius as in a radial current, and the tangential component varies inversely as the radius as in a free vortex. Then the whole velocity at any point will be inversely proportional to the radius of the point, and the fluid will describe stream lines having a constant inclination to the radius drawn to the axis of the current. That is, the stream lines will be logarithmic spirals. When water is delivered from the circumference of a centrifugal pump or turbine into a chamber, it forms a free vortex of this kind. The water flows spirally outwards, its velocity diminishing and its pressure increasing according to the law stated above, and the head along each spiral stream line is constant.

§ 35. *Forced Vortex.*—If the law of motion in a rotating current is different from that in a free vortex, some force must be applied to cause the variation of velocity. The simplest case is that of a rotating current in which all the particles have equal angular velocity, as for instance when they are driven round by radiating paddles revolving uniformly. Then in equation (2), § 33, considering two circular stream lines of radii r and $r+dr$ (fig. 37), we have $\rho = r$, $ds = dr$. If the angular velocity is α, then $v = \alpha r$ and $dv = \alpha dr$. Hence

$$dH = \alpha^2rdr/g + \alpha^2rdr/g = 2\alpha^2rdr/g.$$

Comparing this with (1), § 33, and putting $dz = 0$, because the motion is horizontal,

$$dp/G + \alpha^2rdr/g = 2\alpha^2rdr/g,$$
$$dp/G = \alpha^2rdr/g,$$
$$p/G = \alpha^2r^2/2g + \text{constant}. \qquad (9)$$

Let p_1, r_1, v_1 be the pressure, radius and velocity of one cylindrical section, p_2, r_2, v_2 those of another; then

$$p_1/G - \alpha^2r_1^2/2g = p_2/G - \alpha^2r_2^2/2g;$$
$$(p_2 - p_1)/G = \alpha^2(r_2^2 - r_1^2)/2g = (v_2^2 - v_1^2)/2g. \qquad (10)$$

That is, the pressure increases from within outwards in a curve which in radial sections is a parabola, and surfaces of equal pressure are paraboloids of revolution (fig. 37).

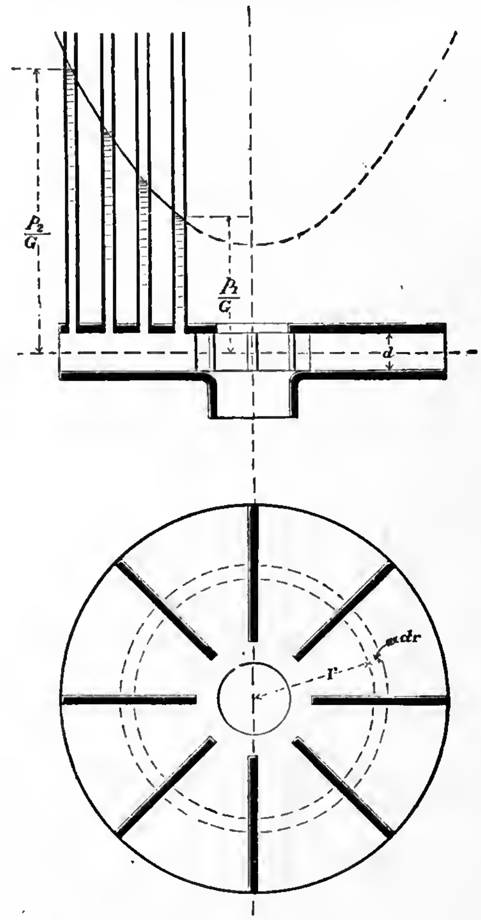

Fig. 37.

Dissipation of Head in Shock

§ 36. *Relation of Pressure and Velocity in a Stream in Steady Motion when the Changes of Section of the Stream are Abrupt.*—When a stream changes section abruptly, rotating eddies are formed which dissipate energy. The energy absorbed in producing rotation is at once abstracted from that effective in causing the flow, and sooner or later it is wasted by frictional resistances due to the rapid relative motion of the eddying parts of the fluid. In such cases the work thus expended internally in the fluid is too important to be neglected, and the energy thus lost is commonly termed energy lost in shock. Suppose fig. 38 to represent a stream having such an abrupt change of section. Let AB, CD be normal sections at points where ordinary stream line motion has not been disturbed and where it has been re-established. Let ω, p, v be the area of section, pressure and velocity at AB, and ω_1, p_1, v_1 corresponding quantities at CD. Then if no work were expended internally, and assuming the stream horizontal, we should have

$$p/G + v^2/2g = p_1/G + v_1^2/2g. \qquad (1)$$

But if work is expended in producing irregular eddying motion, the head at the section CD will be diminished.

Suppose the mass ABCD comes in a short time t to A′B′C′D′. The resultant force parallel to the axis of the stream is

$$p\omega + p_0(\omega_1-\omega) - p_1\omega_1,$$

where p_0 is put for the unknown pressure on the annular space between AB and EF. The impulse of that force is

$$\{p\omega + p_0(\omega_1-\omega) - p_1\omega_1\}t.$$

The horizontal change of momentum in the same time is the difference of the momenta of CDC′D′ and ABA′B′, because the amount of momentum between A′B′ and CD remains unchanged if the motion is steady. The volume of ABA′B′ or CDC′D′, being the inflow and outflow in the time t, is $Qt = \omega vt = \omega_1 v_1 t$, and the momentum of these masses is $(G/g)Qvt$ and $(G/g)Qv_1t$. The change of momentum is therefore $(G/g)Qt(v_1-v)$. Equating this to the impulse,

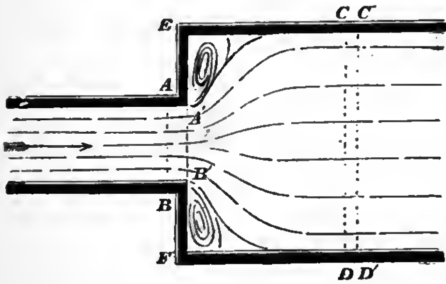

FIG. 38.

$$\{p\omega + p_0(\omega_1-\omega) - p_1\omega_1\}t = (G/g)Qt(v_1-v).$$

Assume that $p_0 = p$, the pressure at AB extending unchanged through the portions of fluid in contact with AE, BF which lie out of the path of the stream. Then (since $Q = \omega_1 v_1$)

$$(p-p_1) = (G/g)v_1(v_1-v);$$

$$p/G - p_1/G = v_1(v_1-v)/g; \qquad (2)$$

$$p/G + v^2/2g = p_1/G + v_1^2/2g + (v-v_1)^2/2g. \qquad (3)$$

This differs from the expression (1), § 29, obtained for cases where no sensible internal work is done, by the last term on the right. That is, $(v-v_1)^2/2g$ has to be added to the total head at CD, which is $p_1/G + v_1^2/2g$, to make it equal to the total head at AB, or $(v-v_1)^2/2g$ is the head lost in shock at the abrupt change of section. But $v-v_1$ is the relative velocity of the two parts of the stream. Hence, when an abrupt change of section occurs, the head due to the relative velocity is lost in shock, or $(v-v_1)^2/2g$ foot-pounds of energy is wasted for each pound of fluid. Experiment verifies this result, so that the assumption that $p_0 = p$ appears to be admissible.

If there is no shock,

$$p_1/G = p/G + (v^2 - v_1^2)/2g.$$

If there is shock,

$$p_1/G = p/G - v_1(v_1-v)/g.$$

Hence the pressure head at CD in the second case is less than in the former by the quantity $(v-v_1)^2/2g$, or, putting $\omega_1 v_1 = \omega v$, by the quantity

$$(v^2/2g)(1-\omega/\omega_1)^2. \qquad (4)$$

V. THEORY OF THE DISCHARGE FROM ORIFICES AND MOUTHPIECES

§ 37. *Minimum Coefficient of Contraction. Re-entrant Mouthpiece of Borda.*—In one special case the coefficient of contraction can be determined theoretically, and, as it is the case where the convergence of the streams approaching the orifice takes place through the greatest possible angle, the coefficient thus determined is the minimum coefficient.

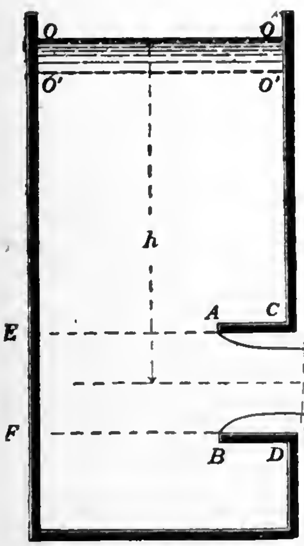

FIG. 39.

Let fig. 39 represent a vessel with vertical sides, OO being the free water surface, at which the pressure is p_a. Suppose the liquid issues by a horizontal mouthpiece, which is re-entrant and of the greatest length which permits the jet to spring clear from the inner end of the orifice, without adhering to its sides. With such an orifice the velocity near the points CD is negligible, and the pressure at those points may be taken equal to the hydrostatic pressure due to the depth from the free surface. Let Ω be the area of the mouthpiece AB, ω that of the contracted jet aa. Suppose that in a short time t, the mass OOaa comes to the position O′O′ $a'a'$; the impulse of the horizontal external forces acting on the mass during that time is equal to the horizontal change of momentum.

The pressure on the side OC of the mass will be balanced by the pressure on the opposite side OE, and so for all other portions of the vertical surfaces of the mass, excepting the portion EF opposite the mouthpiece and the surface AaaB of the jet. On EF the pressure is simply the hydrostatic pressure due to the depth, that is, $(p_a + Gh)\Omega$. On the surface and section AaaB of the jet, the horizontal resultant of the pressure is equal to the atmospheric pressure p_a acting on the vertical projection AB of the jet; that is, the resultant pressure is $-p_a\Omega$. Hence the resultant horizontal force for the whole mass OOaa is $(p_a+Gh)\Omega - p_a\Omega = Gh\Omega$. Its impulse in the time t is $Gh\Omega\, t$. Since the motion is steady there is no change of momentum between O′O′ and aa. The change of horizontal momentum is, therefore, the difference of the horizontal momentum lost in the space OOO′O′ and gained in the space $aaa'a'$. In the former space there is no horizontal momentum.

The volume of the space $aaa'a'$ is ωvt; the mass of liquid in that space is $(G/g)\omega vt$; its momentum is $(G/g)\omega v^2 t$. Equating impulse to momentum gained,

$$Gh\Omega t = (G/g)\omega v^2 t;$$

$$\therefore \omega/\Omega = gh/v^2.$$

But $$v^2 = 2gh, \text{ and } \omega/\Omega = c_c;$$

$$\therefore \omega/\Omega = \tfrac{1}{2} = c_c;$$

a result confirmed by experiment with mouthpieces of this kind. A similar theoretical investigation is not possible for orifices in plane surfaces, because the velocity along the sides of the vessel in the neighbourhood of the orifice is not so small that it can be neglected. The resultant horizontal pressure is therefore greater than $Gh\Omega$, and the contraction is less. The experimental values of the coefficient of discharge for a re-entrant mouthpiece are 0·5149 (Borda), 0·5547 (Bidone), 0·5324 (Weisbach), values which differ little from the theoretical value, 0·5, given above.

§ 38. *Velocity of Filaments issuing in a Jet.*—A jet is composed of fluid filaments or elementary streams, which start into motion at some point in the interior of the vessel from which the fluid is discharged, and gradually acquire the velocity of the jet. Let Mm, fig. 40 be such a filament, the point M being taken where the velocity is insensibly small, and m at the most contracted section of the jet, where the filaments have become parallel and exercise uniform mutual pressure. Take the free surface AB for datum line, and let p_1, v_1, h_1, be the pressure, velocity and depth below datum at M; p, v, h, the corresponding quantities at m. Then § 29, eq. (3a),

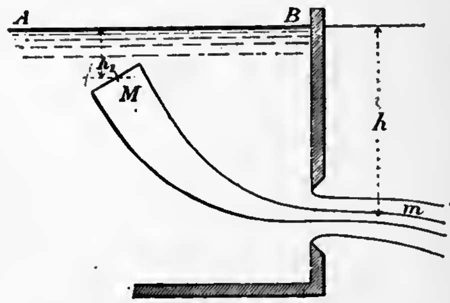

FIG. 40.

$$v_1^2/2g + p_1/G - h_1 = v^2/2g + p/G - h. \qquad (1)$$

But at M, since the velocity is insensible, the pressure is the hydrostatic pressure due to the depth; that is, $v_1 = 0$, $p_1 = p_a + Gh_1$. At m, $p = p_a$, the atmospheric pressure round the jet. Hence, inserting these values,

$$0 + p_a/G + h_1 - h_1 = v^2/2g + p_a/G - h;$$

$$v^2/2g = h; \qquad (2)$$

or $$v = \sqrt{(2gh)} = 8{\cdot}025\sqrt{h}. \qquad (2a)$$

That is, neglecting the viscosity of the fluid, the velocity of filaments at the contracted section of the jet is simply the velocity due to the difference of level of the free surface in the reservoir and the orifice. If the orifice is small in dimensions compared with h, the filaments will all have nearly the same velocity, and if h is measured to the centre of the orifice, the equation above gives the mean velocity of the jet.

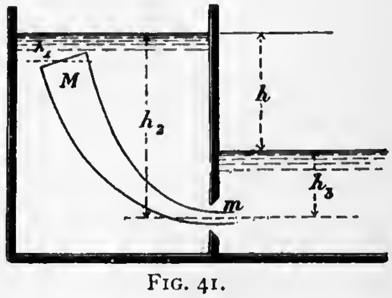

FIG. 41.

Case of a Submerged Orifice.—Let the orifice discharge below the level of the tail water. Then using the notation shown in fig. 41, we have at M, $v_1 = 0$, $p_1 = Gh_1 + p_a$ at m, $p = Gh_3 + p_a$. Inserting these values in (3), § 29,

$$0 + h_1 + p_a/G - h_1 = v^2/2g + h_3 - h_2 + p_a/G;$$

$$v^2/2g = h_2 - h_3 = h, \qquad (3)$$

where h is the difference of level of the head and tail water, and may be termed the *effective head* producing flow.

Case where the Pressures are different on the Free Surface and at the Orifice.—Let the fluid flow from a vessel in which the pressure is p_0 into a vessel in which the pressure is p, fig. 42. The pressure p_0 will produce the same effect as a layer of fluid of thickness p_0/G added to the head water; and the pressure p will produce the same effect as a layer of thickness p/G added to the tail water. Hence the effective difference of level, or effective head producing flow, will be

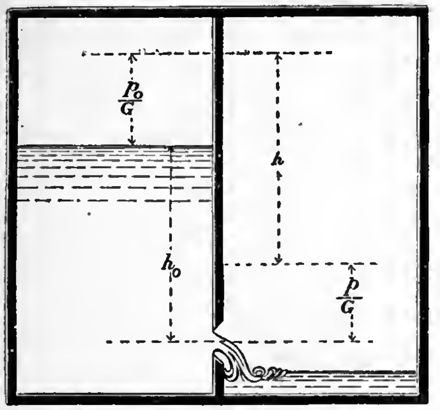

FIG. 42.

$$h = h_0 + p_0/G - p/G;$$

and the velocity of discharge will be

$$v = \sqrt{[2g\{h_0 + (p_0 - p)/G\}]}. \qquad (4)$$

We may express this result by saying that differences of pressure at the free surface and at the orifice are to be reckoned as part of the effective head.

Hence in all cases thus far treated the velocity of the jet is the velocity due to the effective head, and the discharge, allowing for contraction of the jet, is

$$Q = c\omega v = c\omega\sqrt{(2gh)}, \qquad (5)$$

where ω is the area of the orifice, $c\omega$ the area of the contracted section of the jet, and h the effective head measured to the centre of the orifice. If h and ω are taken in feet, Q is in cubic feet per second.

It is obvious, however, that this formula assumes that all the filaments have sensibly the same velocity. That will be true for horizontal orifices, and very approximately true in other cases, if the dimensions of the orifice are not large compared with the head h. In large orifices in say a vertical surface, the value of h is different for different filaments, and then the velocity of different filaments is not sensibly the same.

SIMPLE ORIFICES—HEAD CONSTANT

§ 39. *Large Rectangular Jets from Orifices in Vertical Plane Surfaces.*—Let an orifice in a vertical plane surface be so formed that it produces a jet having a rectangular contracted section with vertical and horizontal sides. Let b (fig. 43) be the breadth of the jet, h_1 and h_2 the depths below the free surface of its upper and lower surfaces. Consider a lamina of the jet between the depths h and $h+dh$. Its normal section is bdh, and the velocity of discharge $\sqrt{2gh}$. The discharge per second in this lamina is therefore $b\sqrt{2gh}\,dh$, and that of the whole jet is therefore

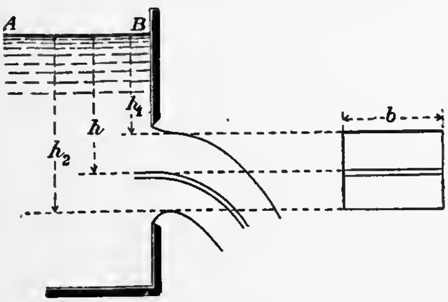

FIG. 43.

$$Q = \int_{h_1}^{h_2} b\sqrt{(2gh)}dh$$
$$= \tfrac{2}{3}b\sqrt{2g}\,\{h_2^{\frac{3}{2}} - h_1^{\frac{3}{2}}\}, \qquad (6)$$

where the first factor on the right is a coefficient depending on the form of the orifice.

Now an orifice producing a rectangular jet must itself be very approximately rectangular. Let B be the breadth, H_1, H_2, the depths to the upper and lower edges of the orifice. Put

$$b(h_2^{\frac{3}{2}} - h_1^{\frac{3}{2}})/B(H_2^{\frac{3}{2}} - H_1^{\frac{3}{2}}) = c. \qquad (7)$$

Then the discharge, in terms of the dimensions of the orifice, instead of those of the jet, is

$$Q = \tfrac{2}{3}cB\sqrt{2g}(H_2^{\frac{3}{2}} - H_1^{\frac{3}{2}}), \qquad (8)$$

the formula commonly given for the discharge of rectangular orifices. The coefficient c is not, however, simply the coefficient of contraction, the value of which is

$$b(h_2 - h_1)/B(H_2 - H_1),$$

and not that given in (7). It cannot be assumed, therefore, that c in equation (8) is constant, and in fact it is found to vary for different values of B/H_2 and B/H_1, and must be ascertained experimentally.

Relation between the Expressions (5) *and* (8).—For a rectangular orifice the area of the orifice is $\omega = B(H_2 - H_1)$, and the depth measured to its centre is $\tfrac{1}{2}(H_2 + H_1)$. Putting these values in (5),

$$Q_1 = cB(H_2 - H_1)\sqrt{\{g(H_2 + H_1)\}}.$$

From (8) the discharge is

$$Q_2 = \tfrac{2}{3}cB\sqrt{2g}(H_2^{\frac{3}{2}} - H_1^{\frac{3}{2}}).$$

Hence, for the same value of c in the two cases,

$$Q_2/Q_1 = \tfrac{2}{3}(H_2^{\frac{3}{2}} - H_1^{\frac{3}{2}})/[(H_2 - H_1)\sqrt{\{(H_2 + H_1)/2\}}].$$

Let $H_1/H_2 = \sigma$, then

$$Q_2/Q_1 = 0{\cdot}9427\ (1 - \sigma^{\frac{3}{2}})/\{1 - \sigma\sqrt{(1+\sigma)}\}. \qquad (9)$$

If H_1 varies from 0 to ∞, $\sigma(=H_1/H_2)$ varies from 0 to 1. The following table gives values of the two estimates of the discharge for different values of σ:—

$H_1/H_2 = \sigma$.	Q_2/Q_1.	$H_1/H_2 = \sigma$.	Q_2/Q_1.
0·0	·943	0·8	·999
0·2	·979	0·9	·999
0·5	·995	1·0	1·000
0·7	·998		

Hence it is obvious that, except for very small values of σ, the simpler equation (5) gives values sensibly identical with those of (8). When $\sigma < 0{\cdot}5$ it is better to use equation (8) with values of c determined experimentally for the particular proportions of orifice which are in question.

§ 40. *Large Jets having a Circular Section from Orifices in a Vertical Plane Surface.*—Let fig. 44 represent the section of the jet, OO being

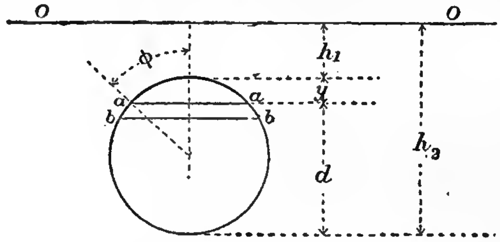

FIG. 44.

the free surface level in the reservoir. The discharge through the horizontal strip $aabb$, of breadth $aa = b$, between the depths $h_1 + y$ and $h_1 + y + dy$, is

$$dQ = b\sqrt{\{2g(h_1 + y)\}}dy.$$

The whole discharge of the jet is

$$Q = \int_0^d b\sqrt{\{2g(h_1 + y)\}}dy.$$

But $b = d\sin\phi$; $y = \tfrac{1}{2}d(1 - \cos\phi)$; $dy = \tfrac{1}{2}d\sin\phi\,d\phi$. Let $\epsilon = d/(2h_1 + d)$, then

$$Q = \tfrac{1}{2}d^2\sqrt{\{2g(h_1 + d/2)\}}\int_0^\pi \sin^2\phi\sqrt{1 - \epsilon\cos\phi}\,d\phi.$$

From eq. (5), putting $\omega = \pi d^2/4$, $h = h_1 + d/2$, $c = 1$ when d is the diameter of the jet and not that of the orifice,

$$Q_1 = \tfrac{1}{4}\pi d^2\sqrt{\{2g(h_1 + d/2)\}},$$
$$Q/Q_1 = 2/\pi\int_0^\pi \sin^2\phi\sqrt{\{1 - \epsilon\cos\phi\}}d\phi.$$

For $h_1 = \infty$, $\epsilon = 0$ and $Q/Q_1 = 1$;
and for $h_1 = 0$, $\epsilon = 1$ and $Q/Q_1 = 0{\cdot}96$.

So that in this case also the difference between the simple formula (5) and the formula above, in which the variation of head at different parts of the orifice is taken into account, is very small.

NOTCHES AND WEIRS

§ 41. *Notches, Weirs and Byewashes.*—A notch is an orifice extending up to the free surface level in the reservoir from which the discharge takes place. A weir is a structure over which the water flows, the discharge being in the same conditions as for a notch. The formula of discharge for an orifice of this kind is ordinarily deduced by putting $H_1 = 0$ in the formula for the corresponding orifice, obtained as in the preceding section. Thus for a rectangular notch, put $H_1 = 0$ in (8). Then

$$Q = \tfrac{2}{3}\,c\,B\sqrt{(2g)}H^{\frac{3}{2}}, \qquad (11)$$

where H is put for the depth to the crest of the weir or the bottom of the notch. Fig. 45 shows the mode in which the discharge occurs in the case of a rectangular notch or weir with a level crest. As the free surface level falls very sensibly near the notch, the head H should be measured at some distance back from the notch, at a point where the velocity of the water is very small.

Since the area of the notch opening is BH, the above formula is of the form

$$Q = c \times BH \times k\sqrt{(2gH)},$$

where k is a factor depending on the form of the notch and expressing the ratio of the mean velocity of discharge to the velocity due to the depth H.

§ 42. *Francis's Formula for Rectangular Notches.*—The jet discharged through a rectangular notch has a section smaller than BH, (a) because of the fall of the water surface from the point where H is measured towards the weir, (*b*) in consequence of the crest contraction, (*c*) in consequence of the end contractions. It may be pointed out that while the diminution of the section of the jet due to the surface fall and to the crest contraction is proportional to the length of the weir, the end contractions have nearly the same effect whether the weir is wide or narrow.

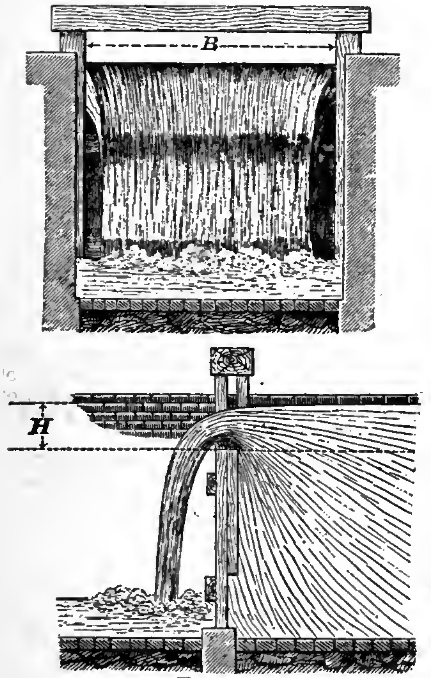

FIG. 45.

J. B. Francis's experiments showed that a perfect end contraction, when the heads varied from 3 to 24 in., and the length of the weir was not less than three times the head, diminished the effective length of the weir by an amount approximately equal to one-tenth of the head. Hence, if l is the length of the notch or weir, and H the head measured behind the weir where the water is nearly still, then the width of the jet passing through the notch would be $l-0{\cdot}2\mathrm{H}$, allowing for two end contractions. In a weir divided by posts there may be more than two end contractions. Hence, generally, the width of the jet is $l-0{\cdot}1n\mathrm{H}$, where n is the number of end contractions of the stream. The contractions due to the fall of surface and to the crest contraction are proportional to the width of the jet. Hence, if $c\mathrm{H}$ is the thickness of the stream over the weir, measured at the contracted section, the section of the jet will be $c(l-0{\cdot}1n\mathrm{H})\mathrm{H}$ and (§ 41) the mean velocity will be $\tfrac{2}{3}\sqrt{(2g\mathrm{H})}$. Consequently the discharge will be given by an equation of the form

$$\mathrm{Q}=\tfrac{2}{3}c(l-0{\cdot}1n\mathrm{H})\mathrm{H}\sqrt{2g\mathrm{H}}$$
$$=5{\cdot}35c(l-0{\cdot}1n\mathrm{H})\mathrm{H}^{\frac{3}{2}}.$$

This is Francis's formula, in which the coefficient of discharge c is much more nearly constant for different values of l and h than in the ordinary formula. Francis found for c the mean value 0·622, the weir being sharp-edged.

§ 43. *Triangular Notch* (fig. 46).—Consider a lamina issuing between the depths h and $h+dh$. Its area, neglecting contraction, will be bdh, and the velocity at that depth is $\sqrt{(2gh)}$. Hence the discharge for this lamina is

$$b\sqrt{2gh}\,dh.$$

But $\quad \mathrm{B}/b=\mathrm{H}/(\mathrm{H}-h);\ b=\mathrm{B}(\mathrm{H}-h)/\mathrm{H}.$

Hence discharge of lamina

$$=\mathrm{B}(\mathrm{H}-h)\sqrt{(2gh)}dh/\mathrm{H};$$

and total discharge of notch

$$=\mathrm{Q}=\mathrm{B}\sqrt{(2g)}\int_0^{\mathrm{H}}(\mathrm{H}-h)h^{\frac{1}{2}}dh/\mathrm{H}$$
$$=\tfrac{4}{15}\mathrm{B}\sqrt{(2g)}\mathrm{H}^{\frac{3}{2}}.$$

or, introducing a coefficient to allow for contraction,

$$\mathrm{Q}=\tfrac{4}{15}c\mathrm{B}\sqrt{(2g)}\mathrm{H}^{\frac{3}{2}},$$

When a notch is used to gauge a stream of varying flow, the ratio B/H varies if the notch is rectangular, but is constant if the notch is triangular. This led Professor James Thomson to suspect that the coefficient of discharge, c, would be much more constant with different values of H in a triangular than in a rectangular notch, and this has been experimentally shown to be the case. Hence a triangular notch is more suitable for accurate gaugings than a rectangular notch. For a sharp-edged triangular notch Professor J. Thomson found $c=0{\cdot}617$. It will be seen, as in § 41, that since $\tfrac{1}{2}\mathrm{BH}$ is the area of section of the stream through the notch, the formula is again of the form

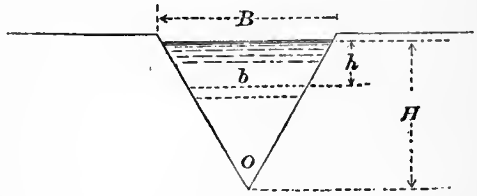

FIG. 46.

$$\mathrm{Q}=c\times\tfrac{1}{2}\mathrm{BH}\times k\sqrt{(2g\mathrm{H})},$$

where $k=\tfrac{8}{15}$ is the ratio of the mean velocity in the notch to the velocity at the depth H. It may easily be shown that for all notches the discharge can be expressed in this form.

§ 44. *Weir with a Broad Sloping Crest.*—Suppose a weir formed with a broad crest so sloped that the streams flowing over it have a movement sensibly rectilinear and uniform (fig. 47). Let the inner edge be so rounded as to prevent a crest contraction. Consider a filament aa', the point a being so far back from the weir that the

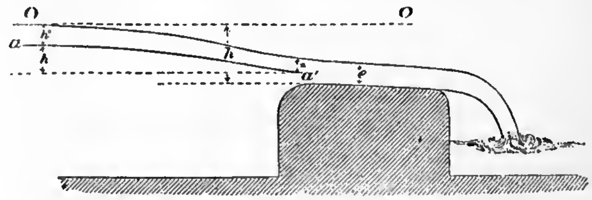

FIG. 47.

velocity of approach is negligible. Let OO be the surface level in the reservoir, and let a be at a height h'' below OO, and h' above a'. Let h be the distance from OO to the weir crest and e the thickness of the stream upon it. Neglecting atmospheric pressure, which has no influence, the pressure at a is $\mathrm{G}h''$; at a' it is $\mathrm{G}z$. If v be the velocity at a',

$$v^2/2g=h'+h''-z=h-e;$$
$$\mathrm{Q}=be\sqrt{2g(h-e)}.$$

Theory does not furnish a value for e, but $\mathrm{Q}=0$ for $e=0$ and for $e=h$. Q has therefore a maximum for a value of e between 0 and h, obtained by equating $d\mathrm{Q}/de$ to zero. This gives $e=\tfrac{2}{3}h$, and, inserting this value,

$$\mathrm{Q}=0{\cdot}385\,bh\sqrt{2gh},$$

as a maximum value of the discharge with the conditions assigned. Experiment shows that the actual discharge is very approximately equal to this maximum, and the formula is more legitimately applicable to the discharge over broad-crested weirs and to cases such as the discharge with free upper surface through large masonry

Coefficients for the Discharge over Weirs, derived from the Experiments of T. E. Blackwell. When more than one experiment was made with the same head, and the results were pretty uniform, the resulting coefficients are marked with an (*). The effect of the converging wing-boards is very strongly marked.

Heads in inches measured from still Water in Reservoir.	Sharp Edge.		Planks 2 in. thick, square on Crest.				Crests 3 ft. wide.

[1] The discharge per second varied from ·461 to ·665 cub. ft. in two experiments. The coefficient ·435 is derived from the mean value.

sluice openings than the ordinary weir formula for sharp-edged weirs. It should be remembered, however, that the friction on the sides and crest of the weir has been neglected, and that this tends to reduce a little the discharge. The formula is equivalent to the ordinary weir formula with $c=0{\cdot}577$.

Special Cases of Discharge from Orifices

§ 45. *Cases in which the Velocity of Approach needs to be taken into Account. Rectangular Orifices and Notches.*—In finding the velocity at the orifice in the preceding investigations, it has been assumed that the head h has been measured from the free surface of still water above the orifice. In many cases which occur in practice the channel of approach to an orifice or notch is not so large, relatively to the stream through the orifice or notch, that the velocity in it can be disregarded.

Let h_1, h_2 (fig. 48) be the heads measured from the free surface to the top and bottom edges of a rectangular orifice, at a point in the

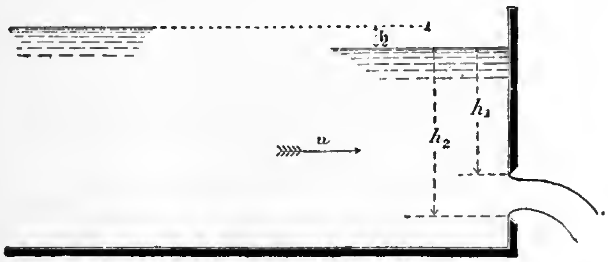

Fig. 48.

channel of approach where the velocity is u. It is obvious that a fall of the free surface,

$$\mathfrak{h}=u^2/2g$$

has been somewhere expended in producing the velocity u, and hence the true heads measured in still water would have been $h_1+\mathfrak{h}$ and $h_2+\mathfrak{h}$. Consequently the discharge, allowing for the velocity of approach, is

$$Q=\tfrac{2}{3}cb\sqrt{2g}\{(h_2+\mathfrak{h})^{\frac{3}{2}}-(h_1+\mathfrak{h})^{\frac{3}{2}}\}. \qquad (1)$$

And for a rectangular notch for which $h_1=0$, the discharge is

$$Q=\tfrac{2}{3}cb\sqrt{2g}\{(h_2+\mathfrak{h})^{\frac{3}{2}}-\mathfrak{h}^{\frac{3}{2}}\}. \qquad (2)$$

In cases where u can be directly determined, these formulae give the discharge quite simply. When, however, u is only known as a function of the section of the stream in the channel of approach, they become complicated. Let Ω be the sectional area of the channel where h_1 and h_2 are measured. Then $u=Q/\Omega$ and $\mathfrak{h}=Q^2/2g\ \Omega^2$.

This value introduced in the equations above would render them excessively cumbrous. In cases therefore where Ω only is known, it is best to proceed by approximation. Calculate an approximate value Q' of Q by the equation

$$Q'=\tfrac{2}{3}cb\sqrt{2g}\{h_2^{\frac{3}{2}}-h_1^{\frac{3}{2}}\}.$$

Then $\mathfrak{h}=Q'^2/2g\Omega^2$ nearly. This value of $\mathfrak{h}$ introduced in the equations above will give a second and much more approximate value of Q.

§ 46. *Partially Submerged Rectangular Orifices and Notches.*—When the tail water is above the lower but below the upper edge of the orifice, the flow in the two parts of the orifice, into which it is divided by the surface of the tail water, takes place under different conditions. A filament M_1m_1 (fig. 49) in the upper part of the orifice issues with a head h' which may have any value between

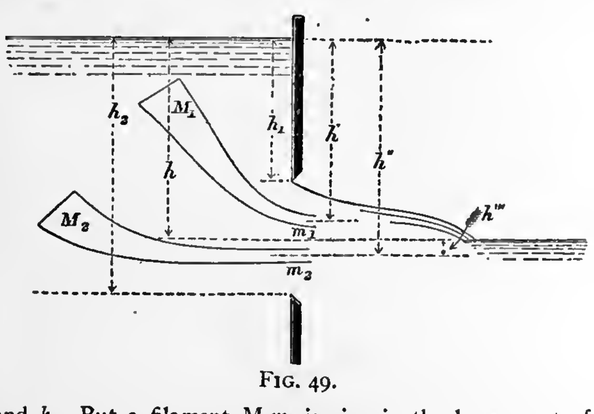

Fig. 49.

h_1 and h. But a filament M_2m_2 issuing in the lower part of the orifice has a velocity due to $h''-h'''$, or h, simply. In the upper part of the orifice the head is variable, in the lower constant. If Q_1, Q_2 are the discharges from the upper and lower parts of the orifice, b the width of the orifice, then

$$\left.\begin{aligned} Q_1&=\tfrac{2}{3}cb\sqrt{2g}\{h^{\frac{3}{2}}-h_1^{\frac{3}{2}}\} \\ Q_2&=cb(h_2-h)\sqrt{2gh} \end{aligned}\right\}. \qquad (3)$$

In the case of a rectangular notch or weir, $h_1=0$. Inserting this value, and adding the two portions of the discharge together, we get for a drowned weir

$$Q=cb\sqrt{2gh}(h_2-h/3), \qquad (4)$$

where h is the difference of level of the head and tail water, and h_2 is the head from the free surface above the weir to the weir crest (fig. 50).

From some experiments by Messrs A. Fteley and F. P. Stearns (*Trans. Am. Soc. C.E.*, 1883, p. 102) some values of the coefficient c can be reduced

h_3/h_2	c	h_3/h_2	c
0·1	0·629	0·7	0·578
0·2	0·614	0·8	0·583
0·3	0·600	0·9	0·596
0·4	0·590	0·95	0·607
0·5	0·582	1·00	0·628
0·6	0·578		

If velocity of approach is taken into account, let $\mathfrak{h}$ be the head due to that velocity; then, adding $\mathfrak{h}$ to each of the heads in the equations (3), and reducing, we get for a weir

$$Q=cb\sqrt{2g}[(h_2+\mathfrak{h})(h+\mathfrak{h})^{\frac{1}{2}}-\tfrac{1}{3}(h+\mathfrak{h})^{\frac{3}{2}}-\tfrac{2}{3}\mathfrak{h}^{\frac{3}{2}}]; \qquad (5)$$

an equation which may be useful in estimating flood discharges.

Bridge Piers and other Obstructions in Streams.—When the piers of a bridge are erected in a stream they create an obstruction to the flow of the stream, which causes a difference of surface-level above and below the pier (fig. 51). If it is necessary to estimate this difference of level, the flow between the piers may be treated as if it occurred over a drowned weir. But the value of c in this case is imperfectly known.

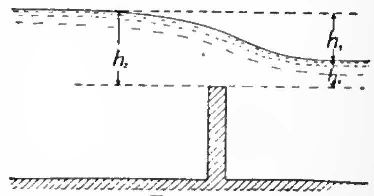

Fig. 50.

§ 47. *Bazin's Researches on Weirs.*—H. Bazin has executed a long series of researches on the flow over weirs, so systematic and complete that they almost supersede other observations. The account of them is contained in a series of papers in the *Annales des Ponts et Chaussées* (October 1888, January 1890, November 1891, February 1894, December 1896, 2nd trimestre 1898). Only a very abbreviated account can be given here. The general plan of the experiments was to establish first the coefficients of discharge for a standard weir without end contractions; next to establish weirs of other types in series with the standard weir on a channel with steady flow, to compare the observed heads on the different weirs and to determine their coefficients from the discharge computed at the standard weir. A channel was constructed parallel to the Canal de Bourgogne, taking water from it through three sluices $0{\cdot}3\times1{\cdot}0$ metres. The water enters a masonry chamber 15 metres long by 4 metres wide where it is stilled and passes into the canal at the end of which is the standard weir. The canal has a length of 15 metres, a width of 2 metres and a depth of 1·6 metres. From

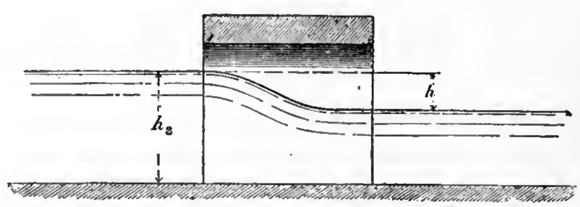

Fig. 51.

this extends a channel 200 metres in length with a slope of 1 mm. per metre. The channel is 2 metres wide with vertical sides. The channels were constructed of concrete rendered with cement. The water levels were taken in chambers constructed near the canal, by floats actuating an index on a dial. Hook gauges were used in determining the heads on the weirs.

Standard Weir.—The weir crest was 3·72 ft. above the bottom of the canal and formed by a plate $\frac{1}{4}$ in. thick. It was sharp-edged with free overfall. It was as wide as the canal so that end contractions were suppressed, and enlargements were formed below the crest to admit air under the water sheet. The channel below the weir was used as a gauging tank. Gaugings were made with the weir 2 metres in length and afterwards with the weir reduced to 1 metre and 0·5 metre in length, the end contractions being suppressed in all cases. Assuming the general formula

$$Q=mlh\sqrt{(2gh)}, \qquad (1)$$

Bazin arrives at the following values of m:—

Coefficients of Discharge of Standard Weir.

Head h metres.	Head h feet.	m
0·05	·164	0·4485
0·10	·328	0·4336
0·15	·492	0·4284
0·20	·656	0·4262
0·25	·820	0·4259
0·30	·984	0·4266
0·35	1·148	0·4275
0·40	1·312	0·4286
0·45	1·476	0·4299
0·50	1·640	0·4313
0·55	1·804	0·4327
0·60	1·968	0·4341

Bazin compares his results with those of Fteley and Stearns in 1877 and 1879, correcting for a different velocity of approach, and finds a close agreement.

Influence of Velocity of Approach.—To take account of the velocity of approach u it is usual to replace h in the formula by $h+\alpha u^2/2g$ where α is a coefficient not very well ascertained. Then

$$Q=\mu l(h+\alpha u^2/2g)\sqrt{\{2g(h+\alpha u^2/2g)\}}$$
$$=\mu lh\sqrt{(2gh)}(1+\alpha u^2/2gh)^{\frac{3}{2}}. \qquad (2)$$

The original simple equation can be used if

$$m=\mu(1+\alpha u^2/2gh)^{\frac{3}{2}}$$

or very approximately, since $u^2/2gh$ is small,

$$m=\mu(1+\tfrac{3}{2}\alpha u^2/2gh). \qquad (3)$$

Now if p is the height of the weir crest above the bottom of the canal (fig. 52), $u=Q/l(p+h)$. Replacing Q by its value in (1)

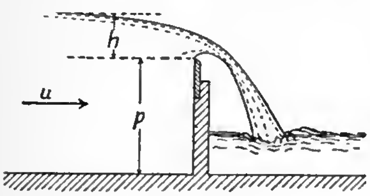

FIG. 52.

$$u^2/2gh=Q^2/\{2ghl^2(p+h)^2\}$$
$$=m^2\{h/(p+h)\}^2, \qquad (4)$$

so that (3) may be written

$$m=\mu[1+k\{h/(p+h)\}^2]. \qquad (5)$$

Gaugings were made with weirs of 0·75, 0·50, 0·35, and 0·24 metres height above the canal bottom and the results compared with those of the standard weir taken at the same time. The discussion of the results leads to the following values of m in the general equation (1):—

$$m=\mu(1+2{\cdot}5u^2/2gh)$$
$$=\mu[1+0{\cdot}55\{h/(p+h)\}^2].$$

Values of μ—

Head h metres.	Head h feet.	μ
0·05	·164	0·4481
0·10	·328	0·4322
0·20	·656	0·4215
0·30	·984	0·4174
0·40	1·312	0·4144
0·50	1·640	0·4118
0·60	1·968	0·4092

An approximate formula for μ is:

$$\mu=0{\cdot}405+0{\cdot}003/h \text{ (} h \text{ in metres)}$$
$$\mu=0{\cdot}405+0{\cdot}01/h \text{ (} h \text{ in feet)}.$$

Inclined Weirs.—Experiments were made in which the plank weir was inclined up or down stream, the crest being sharp and the end contraction suppressed. The following are coefficients by which the discharge of a vertical weir should be multiplied to obtain the discharge of the inclined weir.

		Coefficient.
Inclination up stream . . .	1 to 1	0·93
" "	3 to 2	0·94
" "	3 to 1	0·96
Vertical weir	..	1·00
Inclination down stream . .	3 to 1	1·04
" "	3 to 2	1·07
" "	1 to 1	1·10
" "	1 to 2	1·12
" "	1 to 4	1·09

The coefficient varies appreciably, if h/p approaches unity, which case should be avoided.

In all the preceding cases the sheet passing over the weir is detached completely from the weir and its under-surface is subject to atmospheric pressure. These conditions permit the most exact determination of the coefficient of discharge. If the sides of the canal below the weir are not so arranged as to permit the access of air under the sheet, the phenomena are more complicated. So long as the head does not exceed a certain limit the sheet is detached from the weir, but encloses a volume of air which is at less than atmospheric pressure, and the tail water rises under the sheet. The discharge is a little greater than for free overfall. At greater head the air disappears from below the sheet and the sheet is said to be "drowned." The drowned sheet may be independent of the tail water level or influenced by it. In the former case the fall is followed by a rapid, terminating in a standing wave. In the latter case when the foot of the sheet is drowned the level of the tail water influences the discharge even if it is below the weir crest.

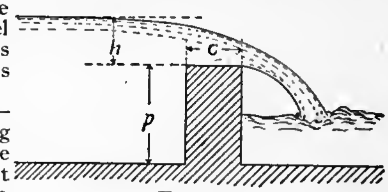

FIG. 53.

Weirs with Flat Crests.—The water sheet may spring clear from the upstream edge or may adhere to the flat crest falling free beyond the downstream edge. In the former case the condition is that of a sharp-edged weir and it is realized when the head is at least double the width of crest. It may arise if the head is at least 1½ the width of crest. Between these limits the condition of the sheet is unstable. When the sheet is adherent the coefficient m depends on the ratio of the head h to the width of crest c (fig. 53), and is given by the equation $m=m_1\ [0{\cdot}70+0{\cdot}185h/c]$, where m_1 is the coefficient for a sharp-edged weir in similar conditions. Rounding the upstream edge even to a small extent modifies the discharge. If R is the radius of the rounding the coefficient m is increased in the ratio 1 to $1+R/h$ nearly. The results are limited to R less than ½ in.

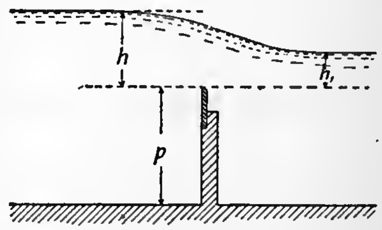

FIG. 54.

Drowned Weirs.—Let h (fig. 54) be the height of head water and h_1 that of tail water above the weir crest. Then Bazin obtains as the approximate formula for the coefficient of discharge

$$m=1{\cdot}05m_1[1+\tfrac{1}{5}h_1/p]\sqrt[3]{\{(h-h_1)/h\}},$$

where as before m_1 is the coefficient for a sharp-edged weir in similar conditions, that is, when the sheet is free and the weir of the same height.

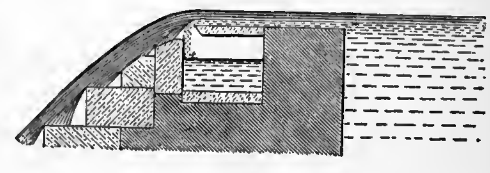

FIG. 55.

§ 48. *Separating Weirs.* — Many towns derive their water-supply from streams in high moorland districts, in which the flow is extremely variable. The water is collected in large storage reservoirs, from which an uniform supply can be sent to the town. In

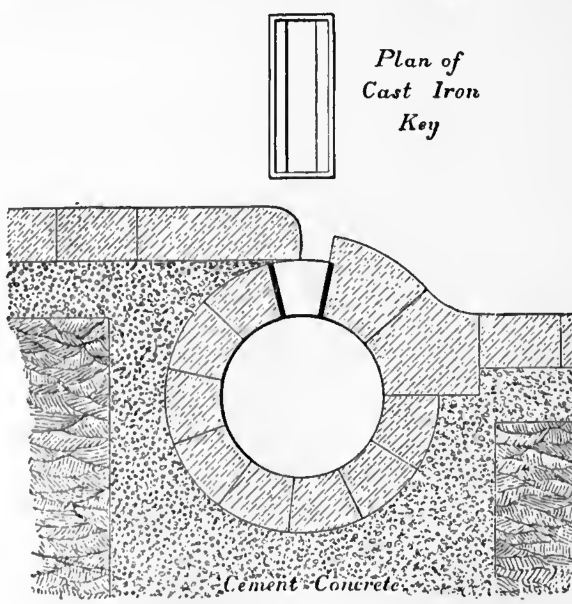

FIG. 56.

such cases it is desirable to separate the coloured water which comes down the streams in high floods from the purer water of ordinary flow. The latter is sent into the reservoirs; the former is allowed to flow away down the original stream channel, or is stored in separate reservoirs and used as compensation water. To accomplish the separation of the flood and ordinary water, advantage is taken of the different horizontal range of the parabolic path of the water falling over a weir, as the depth on the weir and, consequently, the velocity change. Fig. 55 shows one of these separating weirs in the form in which they were first introduced on the Manchester Waterworks; fig. 56 a more modern weir of the same kind designed by Sir A. Binnie for the Bradford Waterworks. When the quantity of water coming down the stream is not excessive, it drops over the weir into a transverse channel leading to the reservoirs. In flood, the water springs over the mouth of this channel and is led into a waste channel.

It may be assumed, probably with accuracy enough for practical purposes, that the particles describe the parabolas due to the mean velocity of the water passing over the weir, that is, to a velocity

$$\tfrac{2}{3}\sqrt{(2gh)},$$

where h is the head above the crest of the weir.

Let $cb=x$ be the width of the orifice and $ac=y$ the difference of level of its edges (fig. 57). Then, if a particle passes from a to b in t seconds,

$$y=\tfrac{1}{2}gt^2,\ x=\tfrac{2}{3}\sqrt{(2gh)}t;$$
$$\therefore\ y=\tfrac{9}{16}x^2/h,$$

which gives the width x for any given difference of level y and head h, which the jet will just pass over the orifice. Set off ad vertically

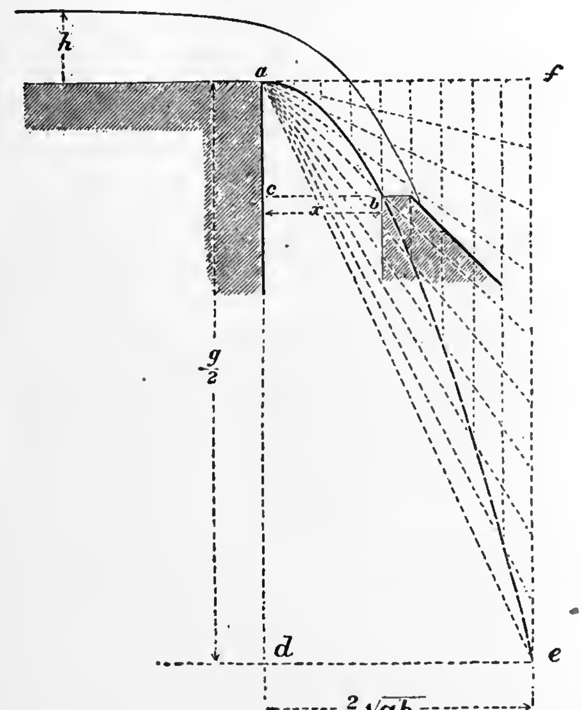

FIG. 57.

and equal to $\frac{1}{2}g$ on any scale; af horizontally and equal to $\frac{2}{3}\sqrt{(gh)}$. Divide af, fe into an equal number of equal parts. Join a with the divisions on ef. The intersections of these lines with verticals from the divisions on af give the parabolic path of the jet.

MOUTHPIECES—HEAD CONSTANT

§ 49. *Cylindrical Mouthpieces.*—When water issues from a short cylindrical pipe or mouthpiece of a length at least equal to $1\frac{1}{2}$ times its smallest transverse dimension, the stream, after contraction within the mouthpiece, expands to fill it and issues full bore, or without contraction, at the point of discharge. The discharge is found to be about one-third greater than that from a simple orifice of the same size. On the other hand, the energy of the fluid per unit of weight is less than that of the stream from a simple orifice with the same head, because part of the energy is wasted in eddies produced at the point where the stream expands to fill the mouthpiece, the action being something like that which occurs at an abrupt change of section.

Let fig. 58 represent a vessel discharging through a cylindrical mouthpiece at the depth h from the free surface, and let the axis of the jet XX be taken as the datum with reference to which the head is estimated. Let Ω be the area of the mouthpiece, ω the area of the stream at the contracted section EF. Let v, p be the velocity and pressure at EF, and v_1, p_1 the same quantities at GH. If the discharge is into the air, p_1 is equal to the atmospheric pressure p_a.

The total head of any filament which goes to form the jet, taken at a point where its velocity is sensibly zero, is $h+p_a/G$; at EF the total head is $v^2/2g+p/G$; at GH it is $v_1^2/2g+p_1/G$.

Between EF and GH there is a loss of head due to abrupt change of velocity, which from eq. (3), § 36, may have the value

$$(v-v_1)^2/2g.$$

Adding this head lost to the head at GH, before equating it to the heads at EF and at the point where the filaments start into motion,—

$$h+p_a/G=v^2/2g+p/G=v_1^2/2g+p_1/G+(v-v_1)^2/2g.$$

But $\omega v=\Omega v_1$, and $\omega=c_c\Omega$, if c_c is the coefficient of contraction within the mouthpiece. Hence

$$v=\Omega v_1/\omega=v_1/c_c.$$

Supposing the discharge into the air, so that $p_1=p_a$,

$$h+p_a/G=v_1^2/2g+p_a/G+(v_1^2/2g)\ (1/c_c-1)^2;$$
$$(v_1/2g)\ \{1+(1/c_c-1)^2\}=h;$$
$$\therefore\ v_1=\sqrt{(2gh)}/\sqrt{\{1+(1/c_c-1)^2\}};\qquad (1)$$

where the coefficient on the right is evidently the coefficient of velocity for the cylindrical mouthpiece in terms of the coefficient of contraction at EF. Let $c_c=0\cdot64$, the value for simple orifices, then the coefficient of velocity is

$$c_v=1/\sqrt{\{1+(1/c_c-1)^2\}}$$
$$=0\cdot87\qquad (2)$$

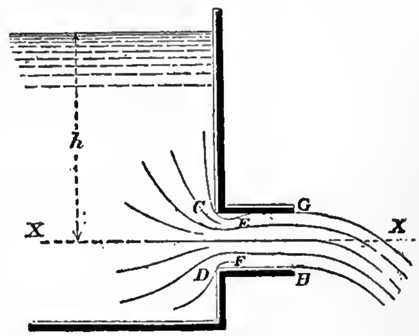

FIG. 58.

The actual value of c_v found by experiment is 0·82, which does not differ more from the theoretical value than might be expected if the friction of the mouthpiece is allowed for. Hence, for mouthpieces of this kind, and for the section at GH,

$$c_v=0\cdot82\quad c_c=1\cdot00\quad c=0\cdot82,$$
$$Q=0\cdot82\Omega\sqrt{(2gh)}.$$

It is easy to see from the equations that the pressure p at EF is less than atmospheric pressure. Eliminating v_1, we get

$$(p_a-p)/G=\tfrac{3}{4}h \text{ nearly};\qquad (3)$$

or

$$p=p_a-\tfrac{3}{4}Gh\text{ lb per sq. ft.}$$

If a pipe connected with a reservoir on a lower level is introduced into the mouthpiece at the part where the contraction is formed (fig. 59), the water will rise in this pipe to a height

$$KL=(p_a-p)/G=\tfrac{3}{4}h \text{ nearly}.$$

If the distance X is less than this, the water from the lower reservoir will be forced continuously into the jet by the atmospheric pressure, and discharged with it. This is the crudest form of a kind of pump known as the jet pump.

§ 50. *Convergent Mouthpieces.*—With convergent mouthpieces there is a contraction within the mouthpiece causing a loss of head, and a diminution of the velocity of discharge, as with cylindrical mouthpieces. There is also a second contraction of the stream outside the mouthpiece. Hence the discharge is given by an equation of the form

$$Q=c_vc_c\Omega\sqrt{(2gh)},\qquad (4)$$

where Ω is the area of the external end of the mouthpiece, and $c_c\Omega$ the section of the contracted jet beyond the mouthpiece.

Convergent Mouthpieces (Castel's Experiments).—Smallest diameter of orifice = 0·05085 ft. Length of mouthpiece = 2·6 Diameters.

Angle of Convergence.	Coefficient of Contraction, c_c	Coefficient of Velocity, c_v	Coefficient of Discharge, c
0° 0′	·999	·830	·829
1° 36′	1·000	·866	·866
3° 10′	1·001	·894	·895
4° 10′	1·002	·910	·912
5° 26′	1·004	·920	·924
7° 52′	·998	·931	·929
8° 58′	·992	·942	·934
10° 20′	·987	·950	·938
12° 4′	·986	·955	·942
13° 24′	·983	·962	·946
14° 28′	·979	·966	·941
16° 36′	·969	·971	·938
19° 28′	·953	·970	·924
21° 0′	·945	·971	·918
23° 0′	·937	·974	·913
29° 58′	·919	·975	·896
40° 20′	·887	·980	·869
48° 50′	·861	·984	·847

The maximum coefficient of discharge is that for a mouthpiece with a convergence of 13° 24′.

The values of c_v and c_c must here be determined by experiment. The above table gives values sufficient for practical purposes. Since the contraction beyond the mouthpiece increases with the convergence, or, what is the same thing, c_c diminishes, and on the other hand the loss of energy diminishes, so that c_v increases with the convergence, there is an angle for which the product $c_c\ c_v$, and consequently the discharge, is a maximum.

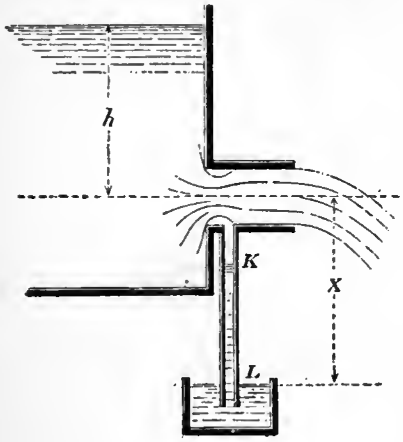

FIG. 59.

§ 51. *Divergent Conoidal Mouthpiece.*—Suppose a mouthpiece so designed that there is no abrupt change in the section or velocity of the stream passing through it. It may have a form at the inner end approximately the same as that of a simple contracted vein, and may then enlarge gradually, as shown in fig. 60. Suppose that at EF it becomes cylindrical, so that the jet may be taken to be of the diameter EF. Let ω, v, p be the section, velocity and pressure at CD, and Ω, v_1, p_1 the same quantities at EF, p_a being as usual the atmospheric pressure, or pressure on the free surface AB. Then, since there is no loss of energy, except the small frictional resistance of the surface of the mouthpiece,

$$h+p_a/G=v^2/2g+p/G$$
$$=v_1^2/2g+p_1/G.$$

If the jet discharges into the air, $p_1=p_a$; and

$$v_1^2/2g=h;$$
$$v_1=\sqrt{(2gh)};$$

or, if a coefficient is introduced to allow for friction,

$$v_1=c_v\sqrt{(2gh)};$$

where c_v is about 0·97 if the mouthpiece is smooth and well formed.

$$Q=\Omega v_1=c_v\Omega\sqrt{(2gh)}.$$

Hence the discharge depends on the area of the stream at EF, and not at all on that at CD, and the latter may be made as small as we please without affecting the amount of water discharged.

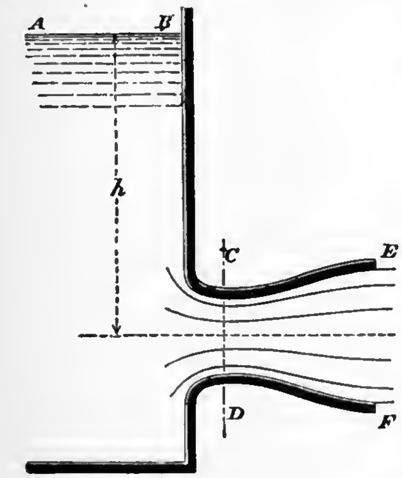

FIG. 60.

There is, however, a limit to this. As the velocity at CD is greater than at EF the pressure is less, and therefore less than atmospheric pressure, if the discharge is into the air. If CD is so contracted that $p=0$, the continuity of flow is impossible. In fact the stream disengages itself from the mouthpiece for some value of p greater than 0 (fig. 61). From the equations,

$$p/G=p_a/G-(v^2-v_1^2)/2g.$$

Let $\Omega/\omega=m$. Then

$$v=v_1 m;$$
$$p/G=p_a/G-v_1^2(m^2-1)/2g$$
$$=p_a/G-(m^2-1)h;$$

whence we find that p/G will become zero or negative if

$$\Omega/\omega \geqq \sqrt{\{(h+p_a/G)/h\}}$$
$$=\sqrt{\{1+p_a/Gh\}};$$

or, putting $p_a/G=34$ ft., if

$$\Omega/\omega \geqq \sqrt{\{(h+34)/h\}}.$$

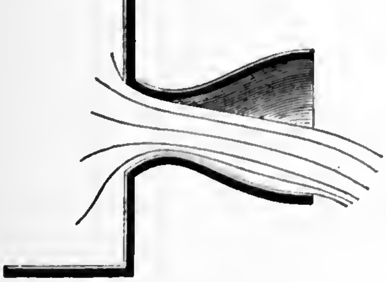

FIG. 61.

In practice there will be an interruption of the full bore flow with a less ratio of Ω/ω, because of the disengagement of air from the water. But, supposing this does not occur, the maximum discharge of a mouthpiece of this kind is

$$Q=\omega\sqrt{\{2g(h+p_a/G)\}};$$

that is, the discharge is the same as for a well-bellmouthed mouthpiece of area ω, and without the expanding part, discharging into a vacuum.

§ 52. *Jet Pump.*—A divergent mouthpiece may be arranged to act as a pump, as shown in fig. 62. The water which supplies the energy required for pumping enters at A. The water to be pumped enters at B. The streams combine at DD where the velocity is greatest and the pressure least. Beyond DD the stream enlarges in section,

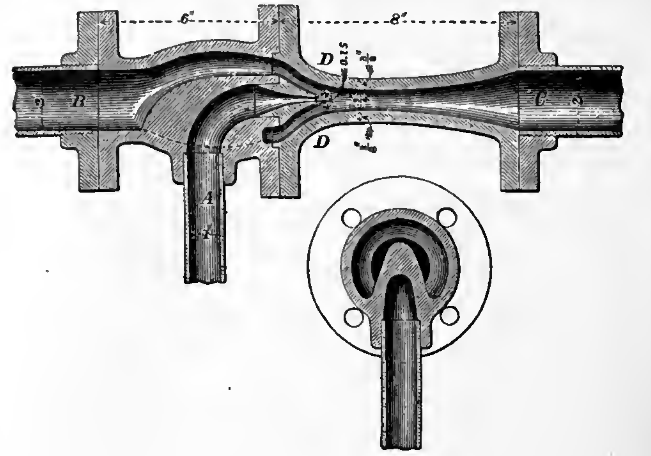

FIG. 62.

and its pressure increases, till it is sufficient to balance the head due to the height of the lift, and the water flows away by the discharge pipe C.

FIG. 63 shows the whole arrangement in a diagrammatic way. A is the reservoir which supplies the water that effects the pumping;

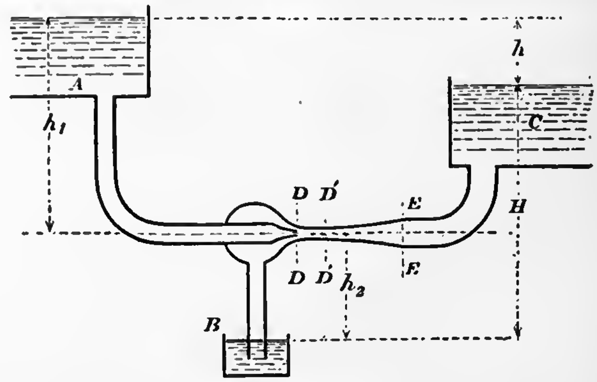

FIG. 63.

B is the reservoir of water to be pumped; C is the reservoir into which the water is pumped.

DISCHARGE WITH VARYING HEAD

§ 53. *Flow from a Vessel when the Effective Head varies with the Time.*—Various useful problems arise relating to the time of emptying and filling vessels, reservoirs, lock chambers, &c., where the flow is dependent on a head which increases or diminishes during the operation. The simplest of these problems is the case of filling or emptying a vessel of constant horizontal section.

Time of Emptying or Filling a Vertical-sided Lock Chamber.—Suppose the lock chamber, which has a water surface of Ω square ft., is emptied through a sluice in the tail gates, of area ω, placed below the tail-water level. Then the effective head producing flow through the sluice is the difference of level in the chamber and tail bay. Let H (fig. 64) be the initial difference of level, h the difference

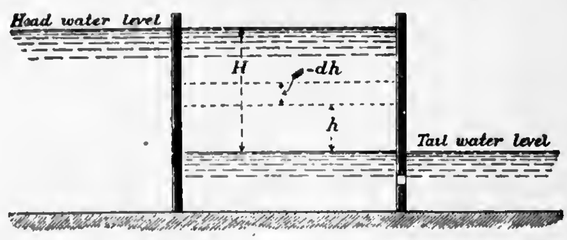

FIG. 64.

of level after t seconds. Let $-dh$ be the fall of level in the chamber during an interval dt. Then in the time dt the volume in the chamber is altered by the amount $-\Omega dh$, and the outflow from the sluice in the same time is $c\omega\sqrt{(2gh)}dt$. Hence the differential equation connecting h and t is

$$c\omega\sqrt{(2gh)}dt+\Omega h=0.$$

For the time t, during which the initial head H diminishes to any other value h,

$$-\{\Omega/(c\omega\sqrt{2g})\}\int_{H}^{h} dh/\sqrt{h} = \int_{0}^{t} dt.$$

$$\therefore t = 2\Omega(\sqrt{H}-\sqrt{h})/\{c\omega\sqrt{(2g)}\}$$
$$= (\Omega/c\omega)\{\sqrt{(2H/g)}-\sqrt{(2h/g)}\}.$$

For the whole time of emptying, during which h diminishes from H to 0,

$$T = (\Omega/c\omega)\sqrt{(2H/g)}.$$

Comparing this with the equation for flow under a constant head, it will be seen that the time is double that required for the discharge of an equal volume under a constant head.

The time of filling the lock through a sluice in the head gates is exactly the same, if the sluice is below the tail-water level. But if the sluice is above the tail-water level, then the head is constant till the level of the sluice is reached, and afterwards it diminishes with the time.

Practical Use of Orifices in Gauging Water

§ 54. If the water to be measured is passed through a known orifice under an arrangement by which the constancy of the head is ensured, the amount which passes in a given time can be ascertained by the formulae already given. It will obviously be best to make the orifices of the forms for which the coefficients are most accurately determined; hence sharp-edged orifices or notches are most commonly used.

Water Inch.—For measuring small quantities of water circular sharp-edged orifices have been used. The discharge from a circular orifice one French inch in diameter, with a head of one line above the top edge, was termed by the older hydraulic writers a water-inch. A common estimate of its value was 14 pints per minute, or 677 English cub. ft. in 24 hours. An experiment by C. Bossut gave 634 cub. ft. in 24 hours (see Navier's edition of *Belidor's Arch. Hydr.*, p. 212).

L. J. Weisbach points out that measurements of this kind would be made more accurately with a greater head over the orifice, and he proposes that the head should be equal to the diameter of the orifice. Several equal orifices may be used for larger discharges.

Pin Ferrules or Measuring Cocks.—To give a tolerably definite supply of water to houses, without the expense of a meter, a ferrule with an orifice of a definite size, or a cock, is introduced in the service-pipe. If the head in the water main is constant, then a definite quantity of water would be delivered in a given time. The arrangement is not a very satisfactory one, and acts chiefly as a check on extravagant use of water. It is interesting here chiefly as an example of regulation of discharge by means of an orifice. Fig. 65 shows a cock of this kind used at Zurich. It consists of three cocks, the middle one having the orifice of the predetermined size in a small circular plate, protected by wire gauze from stoppage by impurities in the water. The cock on the right hand can be used by the consumer for emptying the pipes. The one on the left and the measuring cock are connected by a key which can be locked by a padlock, which is under the control of the water company.

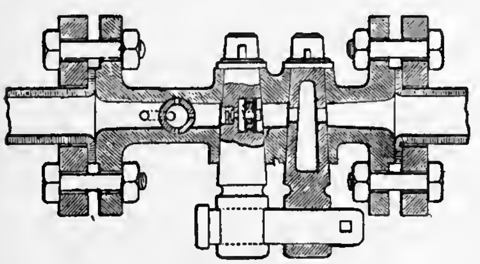

Fig. 65.

§ 55. *Measurement of the Flow in Streams.*—To determine the quantity of water flowing off the ground in small streams, which is available for water supply or for obtaining water power, small temporary weirs are often used. These may be formed of planks supported by piles and puddled to prevent leakage. The measurement of the head may be made by a thin-edged scale at a short distance behind the weir, where the water surface has not begun to slope down to the weir and where the velocity of approach is not high. The measurements are conveniently made from a short pile driven into the bed of the river, accurately level with the crest of the weir (fig. 66). Then if at any moment the head is h, the discharge is, for a rectangular notch of breadth b,

$$Q = \tfrac{2}{3}cbh\sqrt{2gh},$$

where $c = 0{\cdot}62$; or, better, the formula in § 42 may be used.

Gauging weirs are most commonly in the form of rectangular notches; and care should be taken that the crest is accurately horizontal, and that the weir is normal to the direction of flow of the stream. If the planks are thick, they should be bevelled (fig. 67), and then the edge may be protected by a metal plate about $\frac{1}{10}$th in. thick to secure the requisite accuracy of form and sharpness of edge. In permanent gauging weirs, a cast steel plate is sometimes used to form the edge of the weir crest. The weir should be large enough to discharge the maximum volume flowing in the stream, and at the same time it is desirable that the minimum head should not be too small (say half a foot) to decrease the effects of errors of measurement. The section of the jet over the weir should not exceed one-fifth the section of the stream behind the weir, or the velocity of approach will need to be taken into account. A triangular notch is very suitable for measurements of this kind.

If the flow is variable, the head h must be recorded at equidistant intervals of time, say twice daily, and then for each 12-hour period the discharge must be calculated for the mean of the heads at the beginning and end of the time. As this involves a good deal of troublesome calculation, E. Sang proposed to use a scale so graduated as to read off the discharge in cubic feet per second. The lengths of the principal graduations of such a scale are easily calculated by putting $Q = 1, 2, 3 \ldots$ in the ordinary formulae for notches; the intermediate graduations may be taken accurately enough by subdividing equally the distances between the principal graduations.

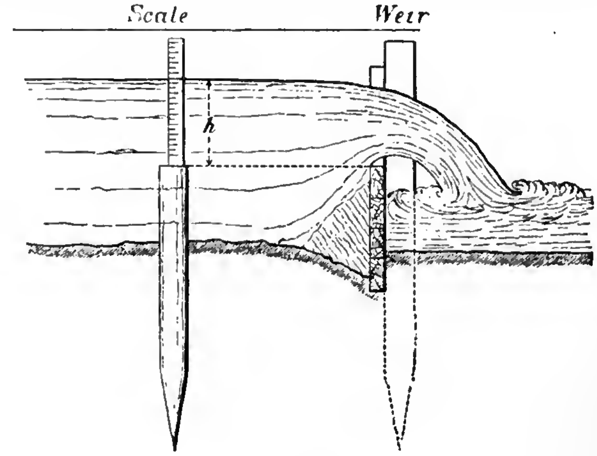

Fig. 66.

The accurate measurement of the discharge of a stream by means of a weir is, however, in practice, rather more difficult than might be inferred from the simplicity of the principle of the operation. Apart from the difficulty of selecting a suitable coefficient of discharge, which need not be serious if the form of the weir and the nature of its crest are properly attended to, other difficulties of measurement arise. The length of the weir should be very accurately determined, and if the weir is rectangular its deviations from exactness of level should be tested. Then the agitation of the water, the ripple on its surface, and the adhesion of the water to the scale on which the head is measured, are liable to introduce errors. Upon a weir 10 ft. long, with 1 ft. depth of water flowing over, an error of 1-1000th of a foot in measuring the head, or an error of 1-100th of a foot in measuring the length of the weir, would cause an error in computing the discharge of 2 cub. ft. per minute.

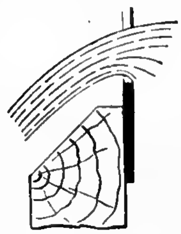

Fig. 67.

Hook Gauge.—For the determination of the surface level of water, the most accurate instrument is the hook gauge used first by U. Boyden of Boston, in 1840. It consists of a fixed frame with scale and vernier. In the instrument in fig. 68 the vernier is fixed to the frame, and the scale slides vertically. The scale carries at its lower end a hook with a fine point, and the scale can be raised or lowered by a fine pitched screw. If the hook is depressed below the water surface and then raised by the screw, the moment of its reaching the water surface will be very distinctly marked, by the reflection from a small capillary elevation of the water surface over the point of the hook. In ordinary light, differences of level of the water of ·001 of a foot are easily detected by the hook gauge. If such a gauge is used to determine the heads at a weir, the hook should

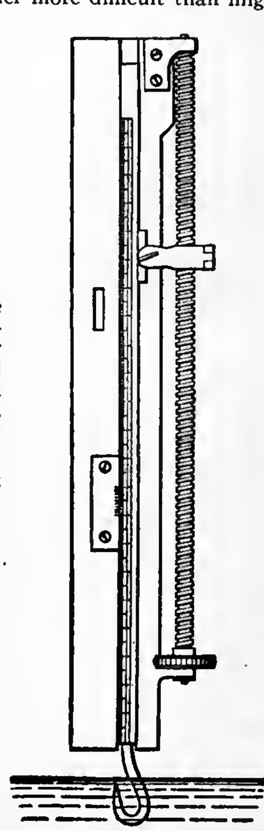

Fig. 68

first be set accurately level with the weir crest, and a reading taken. Then the difference of the reading at the water surface and that for the weir crest will be the head at the weir.

§ 56. *Modules used in Irrigation.*—In distributing water for irrigation, the charge for the water may be simply assessed on the area of the land irrigated for each consumer, a method followed in India; or a regulated quantity of water may be given to each consumer, and the charge may be made proportional to the quantity of water supplied, a method employed for a long time in Italy and other parts of Europe. To deliver a regulated quantity of water

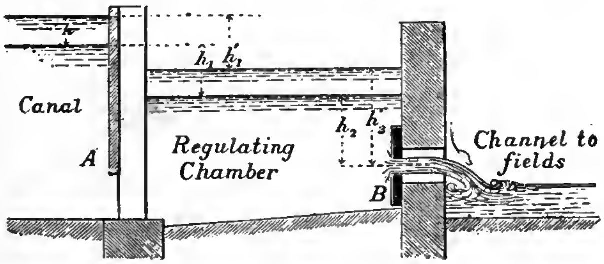

FIG. 69.

from the irrigation channel, arrangements termed modules are used. These are constructions intended to maintain a constant or approximately constant head above an orifice of fixed size, or to regulate the size of the orifice so as to give a constant discharge, notwithstanding the variation of level in the irrigating channel.

§ 57. *Italian Module.*—The Italian modules are masonry constructions, consisting of a regulating chamber, to which water is admitted by an adjustable sluice from the canal. At the other end of the chamber is an orifice in a thin flagstone of fixed size. By means of the adjustable sluice a tolerably constant head above the fixed orifice is maintained, and therefore there is a nearly constant discharge of ascertainable amount through the orifice, into the channel leading to the fields which are to be irrigated.

In fig. 69, A is the adjustable sluice by which water is admitted to the regulating chamber, B is the fixed orifice through which the water is discharged. The sluice A is adjusted from time to time by the canal officers, so as to bring the level of the water in the regulating chamber to a fixed level marked on the wall of the chamber. When

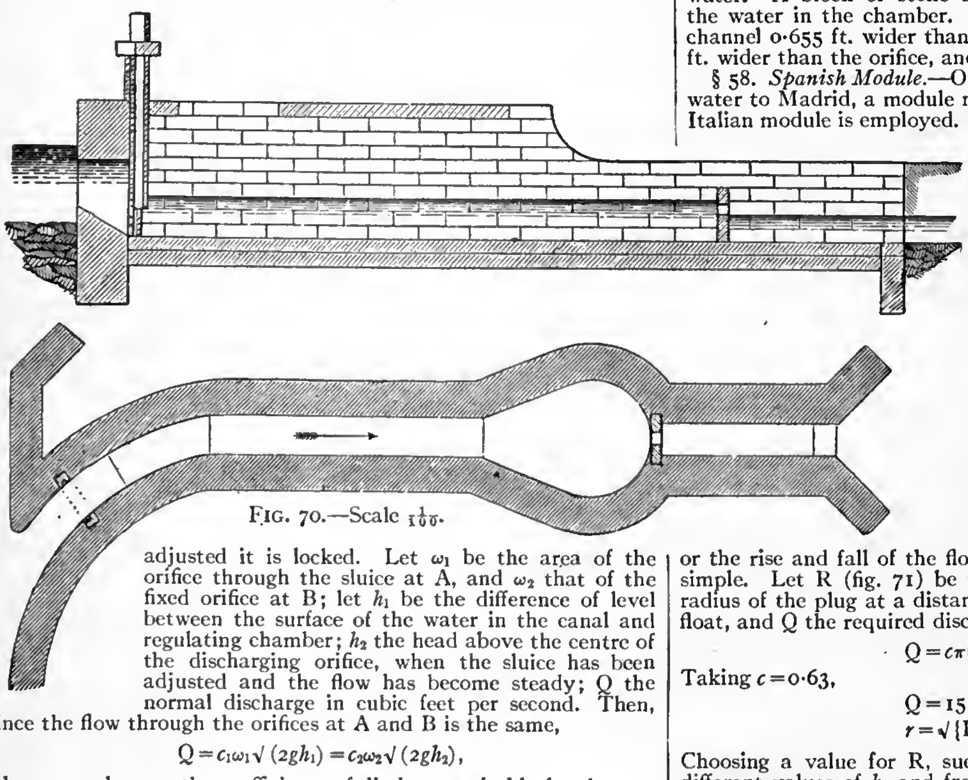

FIG. 70.—Scale $\frac{1}{100}$.

adjusted it is locked. Let ω_1 be the area of the orifice through the sluice at A, and ω_2 that of the fixed orifice at B; let h_1 be the difference of level between the surface of the water in the canal and regulating chamber; h_2 the head above the centre of the discharging orifice, when the sluice has been adjusted and the flow has become steady; Q the normal discharge in cubic feet per second. Then, since the flow through the orifices at A and B is the same,

$$Q = c_1\omega_1\sqrt{(2gh_1)} = c_2\omega_2\sqrt{(2gh_2)},$$

where c_1 and c_2 are the coefficients of discharge suitable for the two orifices. Hence

$$c_1\omega_1/c_2\omega_2 = \sqrt{(h_2/h_1)}.$$

If the orifice at B opened directly into the canal without any intermediate regulating chamber, the discharge would increase for a given change of level in the canal in exactly the same ratio. Consequently the Italian module in no way moderates the fluctuations of discharge, except so far as it affords means of easy adjustment from time to time. It has further the advantage that the cultivator, by observing the level of the water in the chamber, can always see whether or not he is receiving the proper quantity of water.

On each canal the orifices are of the same height, and intended to work with the same normal head, the width of the orifices being varied to suit the demand for water. The unit of discharge varies on different canals, being fixed in each case by legal arrangements. Thus on the Canal Lodi the unit of discharge or one module of water is the discharge through an orifice 1·12 ft. high, 0·12416 ft. wide, with a head of 0·32 ft. above the top edge of the orifice, or ·88 ft. above the centre. This corresponds to a discharge of about 0·6165 cub. ft. per second.

In the most elaborate Italian modules the regulating chamber is arched over, and its dimensions are very exactly prescribed. Thus in the modules of the Naviglio Grande of Milan, shown in fig. 70, the measuring orifice is cut in a thin stone slab, and so placed that the discharge is into the air with free contraction on all sides. The

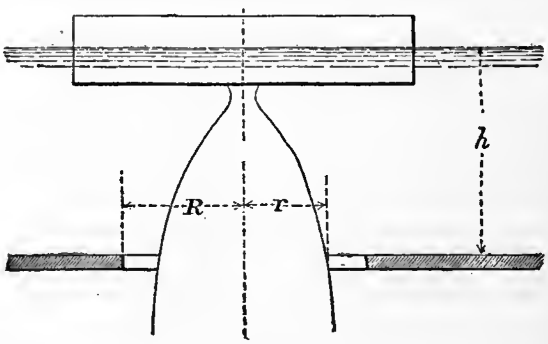

FIG. 71.

adjusting sluice is placed with its sill flush with the bottom of the canal, and is provided with a rack and lever and locking arrangement. The covered regulating chamber is about 20 ft. long, with a breadth 1·64 ft. greater than that of the discharging orifice. At precisely the normal level of the water in the regulating chamber, there is a ceiling of planks intended to still the agitation of the water. A block of stone serves to indicate the normal level of the water in the chamber. The water is discharged into an open channel 0·655 ft. wider than the orifice, splaying out till it is 1·637 ft. wider than the orifice, and about 18 ft. in length.

§ 58. *Spanish Module.*—On the canal of Isabella II., which supplies water to Madrid, a module much more perfect in principle than the Italian module is employed. Part of the water is supplied for irrigation, and as it is very valuable its strict measurement is essential. The module (fig. 72) consists of two chambers one above the other, the upper chamber being in free communication with the irrigation canal, and the lower chamber discharging by a culvert to the fields. In the arched roof between the chambers there is a circular sharp-edged orifice in a bronze plate. Hanging in this there is a bronze plug of variable diameter suspended from a hollow brass float. If the water level in the canal lowers, the plug descends and gives an enlarged opening, and conversely. Thus a perfectly constant discharge with a varying head can be obtained, provided no clogging or silting of the chambers prevents the free discharge of the water or the rise and fall of the float. The theory of the module is very simple. Let R (fig. 71) be the radius of the fixed opening, r the radius of the plug at a distance h from the plane of flotation of the float, and Q the required discharge of the module. Then

$$Q = c\pi(R^2 - r^2)\sqrt{(2gh)}.$$

Taking $c = 0·63$,

$$Q = 15·88(R^2 - r^2)\sqrt{h};$$
$$r = \sqrt{\{R^2 - Q/15·88\sqrt{h}\}}.$$

Choosing a value for R, successive values of r can be found for different values of h, and from these the curve of the plug can be drawn. The module shown in fig. 72 will discharge 1 cubic metre per second. The fixed opening is 0·2 metre diameter, and the greatest head above the fixed orifice is 1 metre. The use of this module involves a great sacrifice of level between the canal and the fields. The module is described in Sir C. Scott-Moncrieff's *Irrigation in Southern Europe.*

§ 59. *Reservoir Gauging Basins.*—In obtaining the power to store the water of streams in reservoirs, it is usual to concede to riparian owners below the reservoirs a right to a regulated supply throughout the year. This compensation water requires to be measured in such a way that the millowners and others interested in the matter can assure themselves that they are receiving a proper quantity, and they are generally allowed a certain amount of control as to the times during which the daily supply is discharged into the stream.

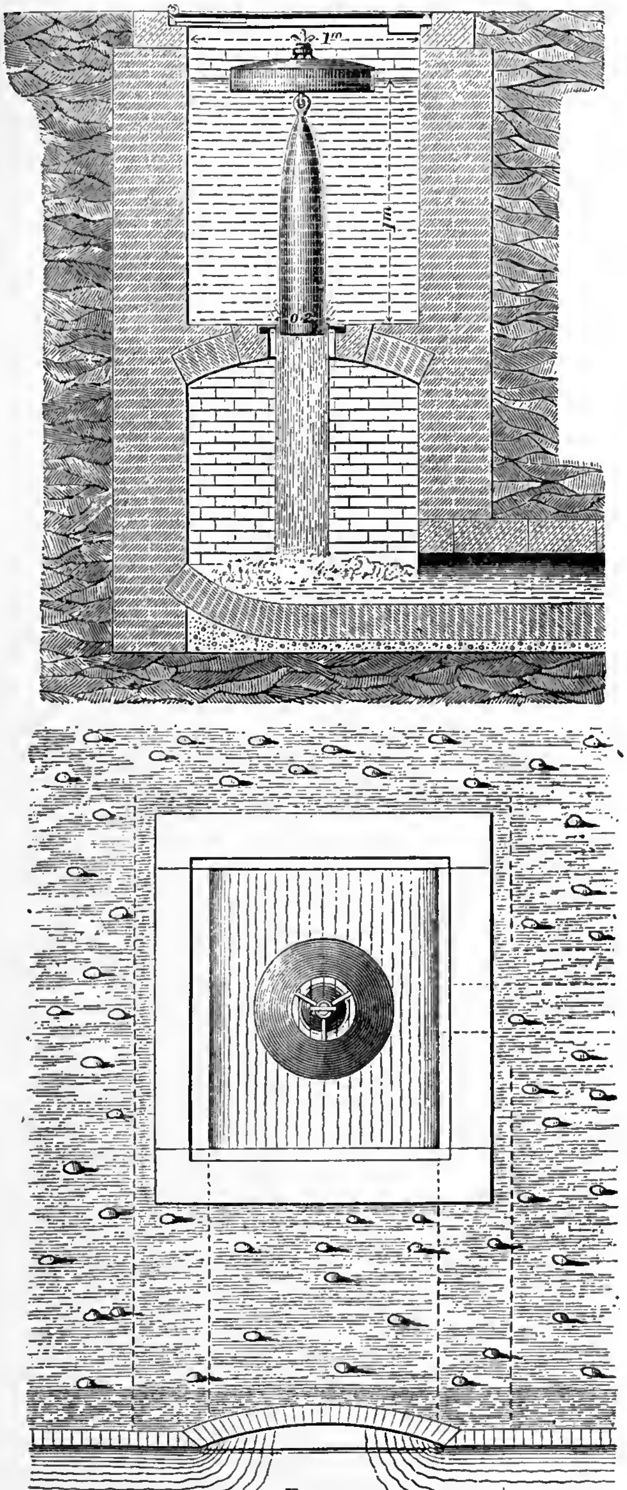

FIG. 72.

Fig. 74 shows an arrangement designed for the Manchester water works. The water enters from the reservoir a chamber A, the object of which is to still the irregular motion of the water. The admission is regulated by sluices at *b*, *b*, *b*. The water is discharged by orifices or notches at *a*, *a*, over which a tolerably constant head is maintained by adjusting the sluices at *b*, *b*, *b*. At any time the millowners can see whether the discharge is given and whether the proper head is maintained over the orifices. To test at any time the discharge of the orifices, a gauging basin B is provided. The water ordinarily flows over this, without entering it, on a floor of cast-iron plates. If the discharge is to be tested, the water is turned for a definite time into the gauging basin, by suddenly opening and closing a sluice at *c*. The volume of flow can be ascertained from the depth in the gauging chamber. A mechanical arrangement (fig. 73) was designed for securing an absolutely constant head over the orifices at *a*, *a*. The orifices were formed in a cast-iron plate capable of sliding up and

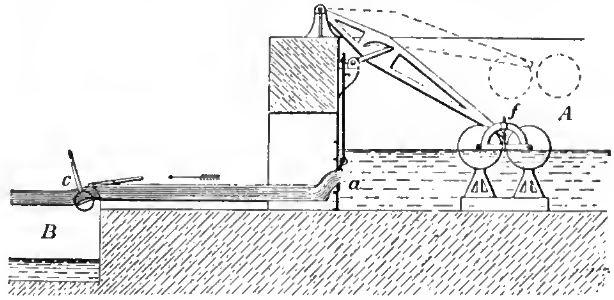

FIG. 73.—Scale $\frac{1}{120}$.

down, without sensible leakage, on the face of the wall of the chamber. The orifice plate was attached by a link to a lever, one end of which rested on the wall and the other on floats *f* in the chamber A. The floats rose and fell with the changes of level in the chamber, and raised and lowered the orifice plate at the same time. This

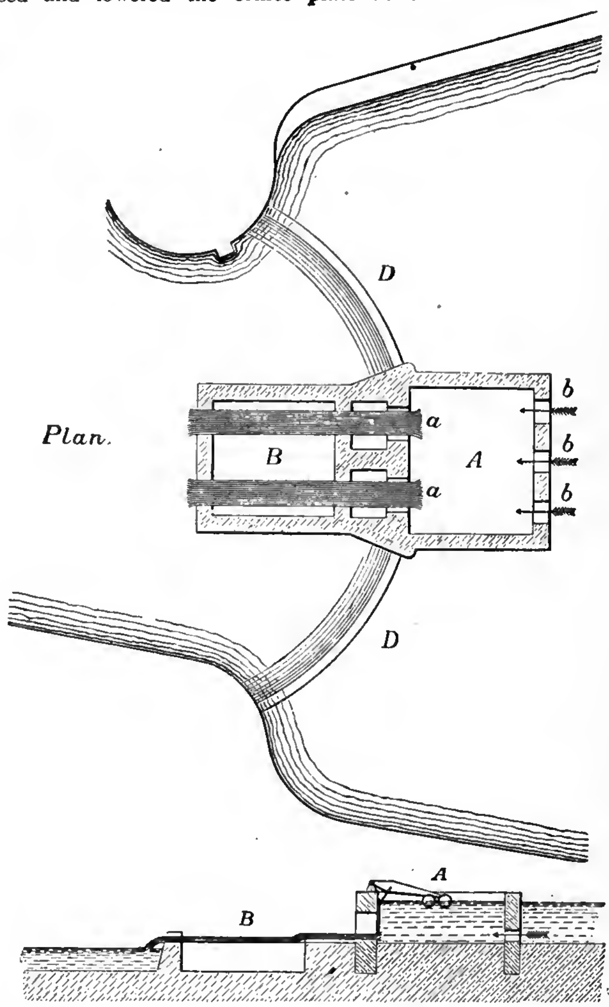

FIG. 74.—Scale $\frac{1}{500}$.

mechanical arrangement was not finally adopted, careful watching of the sluices at *b*, *b*, *b*, being sufficient to secure a regular discharge. The arrangement is then equivalent to an Italian module, but on a large scale.

§ 60. *Professor Fleeming Jenkin's Constant Flow Valve.*—In the modules thus far described constant discharge is obtained by varying the area of the orifice through which the water flows. Professor F. Jenkin has contrived a valve in which a constant pressure head is obtained, so that the orifice need not be varied (*Roy. Scot. Society* *of Arts*, 1876). Fig. 75 shows a valve of this kind suitable for a 6-in. water main. The water arriving by the main C passes through an equilibrium valve D into the chamber A, and thence through a sluice O, which can be set for any required area of opening, into the discharging main B. The object of the arrangement is to secure a constant difference of pressure between the chambers A and B, so that a constant discharge flows through the stop valve O. The equilibrium valve D is rigidly connected with a plunger P loosely fitted in a diaphragm, separating A from a chamber B_2 connected by a pipe B_1 with the discharging main B. Any increase of the difference of pressure in A and B will drive the plunger up and close the

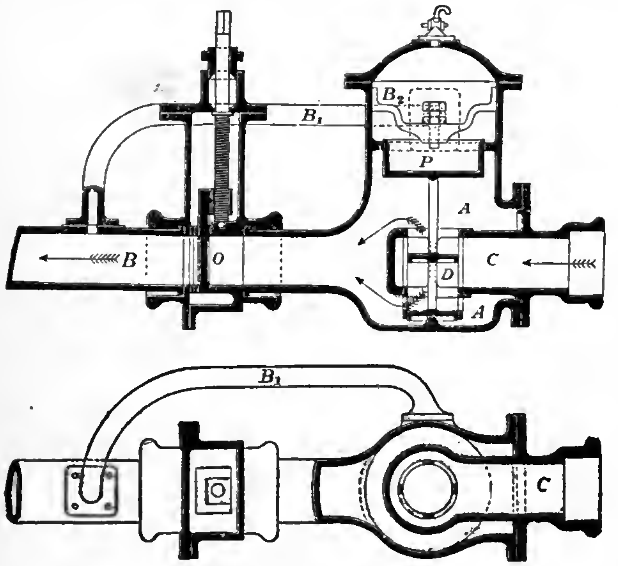

FIG. 75.—Scale $\frac{1}{24}$.

equilibrium valve, and conversely a decrease of the difference of pressure will cause the descent of the plunger and open the equilibrium valve wider. Thus a constant difference of pressure is obtained in the chambers A and B. Let ω be the area of the plunger in square feet, p the difference of pressure in the chambers A and B in pounds per square foot, w the weight of the plunger and valve. Then if at any moment $p\omega$ exceeds w the plunger will rise, and if it is less than w the plunger will descend. Apart from friction, and assuming the valve D to be strictly an equilibrium valve, since ω and w are constant, p must be constant also, and equal to w/ω. By making w small and ω large, the difference of pressure required to ensure the working of the apparatus may be made very small. Valves working with a difference of pressure of $\frac{1}{2}$ in. of water have been constructed.

VI. STEADY FLOW OF COMPRESSIBLE FLUIDS.

§ 61. *External Work during the Expansion of Air.*—If air expands without doing any external work, its temperature remains constant. This result was first experimentally demonstrated by J. P. Joule. It leads to the conclusion that, however air changes its state, the internal work done is proportional to the change of temperature. When, in expanding, air does work against an external resistance, either heat must be supplied or the temperature falls.

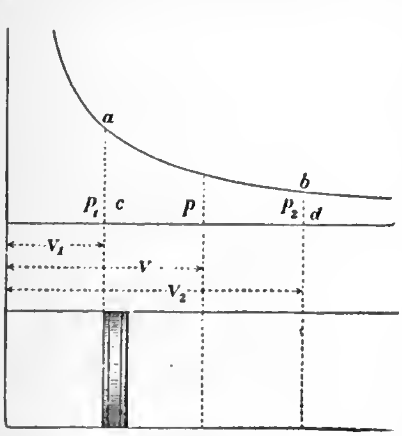

FIG. 76.

To fix the conditions, suppose 1 lb of air confined behind a piston of 1 sq. ft. area (fig. 76). Let the initial pressure be p_1 and the volume of the air v_1, and suppose this to expand to the pressure p_2 and volume v_2. If p and v are the corresponding pressure and volume at any intermediate point in the expansion, the work done on the piston during the expansion from v to $v+dv$ is pdv, and the whole work during the expansion from v_1 to v_2, represented by the area $abcd$, is

$$\int_{v_1}^{v_2} pdv.$$

Amongst possible cases two may be selected.

Case 1.—So much heat is supplied to the air during expansion that the temperature remains constant. Hyperbolic expansion. Then $pv = p_1v_1$.

Work done during expansion per pound of air

$$= \int_{v_1}^{v_2} pdv = p_1v_1 \int_{v_1}^{v_2} dv/v$$
$$= p_1v_1 \log_e v_2/v_1 = p_1v_1 \log_e p_1/p_2. \quad (1)$$

Since the weight per cubic foot is the reciprocal of the volume per pound, this may be written

$$(p_1/G_1) \log_e G_1/G_2. \quad (1a)$$

Then the expansion curve ab is a common hyperbola.

Case 2.—No heat is supplied to the air during expansion. Then the air loses an amount of heat equivalent to the external work done and the temperature falls. Adiabatic expansion.

In this case it can be shown that

$$pv^\gamma = p_1v_1^\gamma,$$

where γ is the ratio of the specific heats of air at constant pressure and volume. Its value for air is 1·408, and for dry steam 1·135.

Work done during expansion per pound of air.

$$= \int_{v_1}^{v_2} pdv = p_1v_1^\gamma \int_{v_1}^{v_2} dv/v^\gamma$$
$$= -\{p_1v_1^\gamma/(\gamma-1)\}\{1/v_2^{\gamma-1} - 1/v_1^{\gamma-1}\}$$
$$= \{p_1v_1^\gamma/(\gamma-1)\}\{1/v_1^{\gamma-1} - 1/v_2^{\gamma-1}\}$$
$$= \{p_1v_1/(\gamma-1)\}\{1-(v_1/v_2)^{\gamma-1}\}. \quad (2)$$

The value of p_1v_1 for any given temperature can be found from the data already given.

As before, substituting the weights G_1, G_2 per cubic foot for the volumes per pound, we get for the work of expansion

$$(p_1/G_1)\{1/(\gamma-1)\}\{1-(G_2/G_1)^{\gamma-1}\}, \quad (2a)$$
$$= p_1v_1\{1/(\gamma-1)\}\{1-(p_2/p_1)^{(\gamma-1)/\gamma}\}. \quad (2b)$$

§ 62. *Modification of the Theorem of Bernoulli for the Case of a Compressible Fluid.*—In the application of the principle of work to a filament of compressible fluid, the internal work done by the expansion of the fluid, or absorbed in its compression, must be taken into account. Suppose, as before, that AB (fig. 77) comes to A′B′ in a short time t. Let p_1, ω_1, v_1, G_1 be the pressure, sectional area of stream, velocity and weight of a cubic foot at A, and p_2, ω_2, v_2, G_2 the same quantities at B. Then, from the steadiness of motion, the weight of fluid passing A in any given time must be equal to the weight passing B:

FIG. 77.

$$G_1\omega_1v_1t = G_2\omega_2v_2t.$$

Let z_1, z_2 be the heights of the sections A and B above any given datum. Then the work of gravity on the mass AB in t seconds is

$$G_1\omega_1v_1t(z_1-z_2) = W(z_1-z_2)t,$$

where W is the weight of gas passing A or B per second. As in the case of an incompressible fluid, the work of the pressures on the ends of the mass AB is

$$p_1\omega_1v_1t - p_2\omega_2v_2t,$$
$$= (p_1/G_1 - p_2/G_2)Wt.$$

The work done by expansion of Wt lb of fluid between A and B is $Wt\int_{v_1}^{v_2} pdv$. The change of kinetic energy as before is $(W/2g)(v_2^2-v_1^2)t$. Hence, equating work to change of kinetic energy,

$$W(z_1-z_2)t + (p_1/G_1 - p_2/G_2)Wt + Wt\int_{v_1}^{v^2} pdv = (W/2g)(v_2^2-v_1^2)t;$$
$$\therefore z_1 + p_1/G_1 + v_1^2/2g = z_2 + p^2/G_2 + v_2^2/2g - \int_{v_1}^{v_2} pdv. \quad (1)$$

Now the work of expansion per pound of fluid has already been given. If the temperature is constant, we get (eq. 1*a*, § 61)

$$z_1 + p_1/G_1 + v_1^2/2g = z_2 + p_2/G_2 + v_2^2/2g - (p_1/G_1)\log_e(G_1/G_2).$$

But at constant temperature $p_1/G_1 = p_2/G_2$;

$$\therefore z_1 + v_1^2/2g = z_2 + v_2^2/2g - (p_1/G_1)\log_e(p_1/p_2), \quad (2)$$

or, neglecting the difference of level,

$$(v_2^2 - v_1^2)/2g = (p_1/G_1)\log_e(p_1/p_2). \quad (2a)$$

Similarly, if the expansion is adiabatic (eq. 2*a*, § 61),

$$z_1 + p_1/G_1 + v_1^2/2g = z_2 + p_2/G_2 + v_2^2/2g - (p_1/G_1)\{1/(\gamma-1)\}\{1-(p_2/p_1)^{(\gamma-1)/\gamma}\}; \quad (3)$$

or neglecting the difference of level

$$(v_2^2 - v_1^2)/2g = (p_1/G_1)[1 + 1/(\gamma-1)\{1-(p_2/p_1)^{(\gamma-1)/\gamma}\}] - p_2/G_2. \quad (3a)$$

It will be seen hereafter that there is a limit in the ratio p_1/p_2 beyond which these expressions cease to be true.

§ 63. *Discharge of Air from an Orifice.*—The form of the equation of work for a steady stream of compressible fluid is

$$z_1 + p_1/G_1 + v_1^2/2g = z_2 + p_2/G_2 + v_2^2/2g - (p_1/G_1)\{1/(\gamma-1)\}\{1-(p_2/p_1)^{(\gamma-1)/\gamma}\},$$

the expansion being adiabatic, because in the flow of the streams of air through an orifice no sensible amount of heat can be communicated from outside.

Suppose the air flows from a vessel, where the pressure is p_1 and the velocity sensibly zero, through an orifice, into a space where the pressure is p_2. Let v_2 be the velocity of the jet at a point where the convergence of the streams has ceased, so that the pressure in the jet is also p_2. As air is light, the work of gravity will be small compared with that of the pressures and expansion, so that $z_1 z_2$ may be neglected. Putting these values in the equation above—

$$p_1/G_1 = p_2/G_2 + v_2^2/2g - (p_1/G_1)\{1/(\gamma-1)\}\{1-(p_2/p_1)^{(\gamma-1)/\gamma}\};$$

$$v_2^2/2g = p_1/G_1 - p_2/G_2 + (p_1/G_1)\{1/(\gamma-1)\}\{1-(p_2/p_1)^{(\gamma-1)/\gamma}\}$$

$$= (p_1/G_1)\{\gamma/(\gamma-1) - (p_2/p_1)^{\gamma-1/\gamma}/(\gamma-1)\} - p_2/G_2.$$

But $\quad p_1/G_1^{\gamma} = p_2/G_2^{\gamma} \quad \therefore \; p_2/G_2 = (p_1/G_1)(p_2/p_1)^{(\gamma-1)/\gamma}$

$$v_2^2/2g = (p_1/G_1)\{\gamma/(\gamma-1)\}\{1-(p_2/p_1)^{(\gamma-1)/\gamma}\}; \qquad (1)$$

or $\quad v_2^2/2g = \{\gamma/(\gamma-1)\}\{(p_1/G_1)-(p_2/G_2)\};$

an equation commonly ascribed to L. J. Weisbach (*Civilingenieur*, 1856), though it appears to have been given earlier by A. J. C. Barre de Saint Venant and L. Wantzel.

It has already (§ 9, eq. 4*a*) been seen that

$$p_1/G_1 = (p_0/G_0)(\tau_1/\tau_0)$$

where for air $p_0 = 2116{\cdot}8$, $G_0 = {\cdot}08075$ and $\tau_0 = 492{\cdot}6$.

$$v_2^2/2g = \{p_0\tau_1\gamma/G_0\tau_0(\gamma-1)\}\{1-(p_2/p_1)^{(\gamma-1)/\gamma}\}; \qquad (2)$$

or, inserting numerical values,

$$v_2^2/2g = 183{\cdot}6\tau_1\{1-(p_2/p_1)^{0{\cdot}29}\}; \qquad (2a)$$

which gives the velocity of discharge v_2 in terms of the pressure and absolute temperature, p_1, τ_1, in the vessel from which the air flows, and the pressure p_2 in the vessel into which it flows.

Proceeding now as for liquids, and putting ω for the area of the orifice and c for the coefficient of discharge, the volume of air discharged per second at the pressure p_2 and temperature τ_2 is

$$Q_2 = c\omega v_2 = c\omega\sqrt{[(2g\gamma p_1/(\gamma-1)G_1)(1-(p_2/p_1)^{(\gamma-1)/\gamma})]}$$

$$= 108{\cdot}7c\omega\sqrt{[\tau_1\{1-(p_2/p_1)^{0{\cdot}29}\}]}. \qquad (3)$$

If the volume discharged is measured at the pressure p_1 and absolute temperature τ_1 in the vessel from which the air flows, let Q_1 be that volume; then

$$p_1 Q_1^{\gamma} = p_2 Q_2^{\gamma};$$

$$Q_1 = (p_2/p_1)^{1/\gamma} Q_2;$$

$$Q_1 = c\omega\sqrt{[\{2g\gamma p_1/(\gamma-1)G_1\}\{(p_2/p_1)^{2/\gamma}-(p_2/p_1)^{(\gamma+1)/\gamma}\}]}.$$

Let $\quad (p_2/p_1)^{2/\gamma} - (p_2/p_1)^{(\gamma-1)/\gamma} = (p_2/p_1)^{1{\cdot}41} - (p_2/p_1)^{1{\cdot}7} = \psi$; then

$$Q_1 = c\omega\sqrt{[2g\gamma p_1\psi/(\gamma-1)G_1]}$$

$$= 108{\cdot}7c\omega\sqrt{(\tau_1\psi)}. \qquad (4)$$

The weight of air at pressure p_1 and temperature τ_1 is

$$G_1 = p_1/53{\cdot}2\tau_1 \text{ lb per cubic foot.}$$

Hence the weight of air discharged is

$$W = G_1 Q_1 = c\omega\sqrt{[2g\gamma p_1 G_1\psi/(\gamma-1)]}$$

$$= 2{\cdot}043c\omega p_1\sqrt{(\psi/\tau_1)}. \qquad (5)$$

Weisbach found the following values of the coefficient of discharge c:—

	$c=$
Conoidal mouthpieces of the form of the contracted vein with effective pressures of ·23 to 1·1 atmosphere	0·97 to 0·99
Circular sharp-edged orifices	0·563 „ 0·788
Short cylindrical mouthpieces	0·81 „ 0·84
The same rounded at the inner end	0·92 „ 0·93
Conical converging mouthpieces	0·90 „ 0·99

§ 64. *Limit to the Application of the above Formulae.*—In the formulae above it is assumed that the fluid issuing from the orifice expands from the pressure p_1 to the pressure p_2, while passing from the vessel to the section of the jet considered in estimating the area ω. Hence p_2 is strictly the pressure in the jet at the plane of the external orifice in the case of mouthpieces, or at the plane of the contracted section in the case of simple orifices. Till recently it was tacitly assumed that this pressure p_2 was identical with the general pressure external to the orifice. R. D. Napier first discovered that, when the ratio p_2/p_1 exceeded a value which does not greatly differ from 0·5, this was no longer true. In that case the expansion of the fluid down to the external pressure is not completed at the time it reaches the plane of the contracted section, and the pressure there is greater than the general external pressure; or, what amounts to the same thing, the section of the jet where the expansion is completed is a section which is greater than the area $c_c\omega$ of the contracted section of the jet, and may be greater than the area ω of the orifice. Napier made experiments with steam which showed that, so long as $p_2/p_1 > 0{\cdot}5$, the formulae above were trustworthy, when p_2 was taken to be the general external pressure, but that, if $p_2/p_1 < 0{\cdot}5$, then the pressure at the contracted section was independent of the external pressure and equal to $0{\cdot}5p_1$. Hence in such cases the constant value 0·5 should be substituted in the formulae for the ratio of the internal and external pressures p_2/p_1.

It is easily deduced from Weisbach's theory that, if the pressure external to an orifice is gradually diminished, the weight of air discharged per second increases to a maximum for a value of the ratio

$$p_2/p_1 = \{2/(\gamma+1)\}^{\gamma-1/\gamma}$$

$$= 0{\cdot}527 \text{ for air}$$

$$= 0{\cdot}58 \text{ for dry steam.}$$

For a further decrease of external pressure the discharge diminishes,—a result no doubt improbable. The new view of Weisbach's formula is that from the point where the maximum is reached, or not greatly differing from it, the pressure at the contracted section ceases to diminish.

A. F. Fliegner showed (*Civilingenieur* xx., 1874) that for air flowing from well-rounded mouthpieces there is no discontinuity of the law of flow, as Napier's hypothesis implies, but the curve of flow bends so sharply that Napier's rule may be taken to be a good approximation to the true law. The limiting value of the ratio p_2/p_1, for which Weisbach's formula, as originally understood, ceases to apply, is for air 0·5767; and this is the number to be substituted for p_2/p_1 in the formulae when p_2/p_1 falls below that value. For later researches on the flow of air, reference may be made to G. A. Zeuner's paper (*Civilingenieur*, 1871), and Fliegner's papers (*ibid.*, 1877, 1878).

VII. FRICTION OF LIQUIDS.

§ 65. When a stream of fluid flows over a solid surface, or conversely when a solid moves in still fluid, a resistance to the motion is generated, commonly termed fluid friction. It is due to the viscosity of the fluid, but generally the laws of fluid friction are very different from those of simple viscous resistance. It would appear that at all speeds, except the slowest, rotating eddies are formed by the roughness of the solid surface, or by abrupt changes of velocity distributed throughout the fluid; and the energy expended in producing these eddying motions is gradually lost in overcoming the viscosity of the fluid in regions more or less distant from that where they are first produced.

The laws of fluid friction are generally stated thus:—

1. The frictional resistance is independent of the pressure between the fluid and the solid against which it flows. This may be verified by a simple direct experiment. C. H. Coulomb, for instance, oscillated a disk under water, first with atmospheric pressure acting on the water surface, afterwards with the atmospheric pressure removed. No difference in the rate of decrease of the oscillations was observed. The chief proof that the friction is independent of the pressure is that no difference of resistance has been observed in water mains and in other cases, where water flows over solid surfaces under widely different pressures.

2. The frictional resistance of large surfaces is proportional to the area of the surface.

3. At low velocities of not more than 1 in. per second for water, the frictional resistance increases directly as the relative velocity of the fluid and the surface against which it flows. At velocities of ½ ft. per second and greater velocities, the frictional resistance is more nearly proportional to the square of the relative velocity.

In many treatises on hydraulics it is stated that the frictional resistance is independent of the nature of the solid surface. The explanation of this was supposed to be that a film of fluid remained attached to the solid surface, the resistance being generated between this fluid layer and layers more distant from the surface. At extremely low velocities the solid surface does not seem to have much influence on the friction. In Coulomb's experiments a metal surface covered with tallow, and oscillated in water, had exactly the same resistance as a clean metal surface, and when sand was scattered over the tallow the resistance was only very slightly increased. The earlier calculations of the resistance of water at higher velocities in iron and wood pipes and earthen channels seemed to give a similar result. These, however, were erroneous, and it is now well understood that differences of roughness of the solid surface very greatly influence the friction, at such velocities as are common in engineering practice. H. P. G. Darcy's experiments, for instance, showed that in old and incrusted water mains the resistance was twice or sometimes thrice as great as in new and clean mains.

§ 66. *Ordinary Expressions for Fluid Friction at Velocities not Extremely Small.*—Let f be the frictional resistance estimated in pounds per square foot of surface at a velocity of 1 ft. per second; ω the area of the surface in square feet; and v its velocity in feet per second relatively to the water in which it is immersed. Then, in accordance with the laws stated above, the total resistance of the surface is

$$R = f\omega v^2 \qquad (1)$$

where f is a quantity approximately constant for any given surface. If

$$\xi = 2gf/G,$$

$$R = \xi G\omega v^2/2g, \qquad (2)$$

where ξ is, like f, nearly constant for a given surface, and is termed the coefficient of friction.

The following are average values of the coefficient of friction for water, obtained from experiments on large plane surfaces, moved in an indefinitely large mass of water.

	Coefficient of Friction, ξ	Frictional Resistance in lb per sq. ft. f
New well-painted iron plate . . .	·00489	·00473
Painted and planed plank (Beaufoy)	·00350	·00339
Surface of iron ships (Rankine) . .	·00362	·00351
Varnished surface (Froude) . . .	·00258	·00250
Fine sand surface ,, . . .	·00418	·00405
Coarser sand surface ,, ...	·00503	·00488

The distance through which the frictional resistance is overcome is v ft. per second. The work expended in fluid friction is therefore given by the equation—

$$\left.\begin{aligned}\text{Work expended} &= f\omega v^3 \text{ foot-pounds per second}\\ &= \xi G\omega v^3/2g \quad ,, \quad ,,\end{aligned}\right\} \quad (3).$$

The coefficient of friction and the friction per square foot of surface can be indirectly obtained from observations of the discharge of pipes and canals. In obtaining them, however, some assumptions as to the motion of the water must be made, and it will be better therefore to discuss these values in connexion with the cases to which they are related.

Many attempts have been made to express the coefficient of friction in a form applicable to low as well as high velocities. The older hydraulic writers considered the resistance termed fluid friction to be made up of two parts,—a part due directly to the distortion of the mass of water and proportional to the velocity of the water relatively to the solid surface, and another part due to kinetic energy imparted to the water striking the roughnesses of the solid surface and proportional to the square of the velocity. Hence they proposed to take

$$\xi = \alpha + \beta/v$$

in which expression the second term is of greatest importance at very low velocities, and of comparatively little importance at velocities over about ½ ft. per second. Values of ξ expressed in this and similar forms will be given in connexion with pipes and canals.

All these expressions must at present be regarded as merely empirical expressions serving practical purposes.

The frictional resistance will be seen to vary through wider limits than these expressions allow, and to depend on circumstances of which they do not take account.

§ 67. *Coulomb's Experiments.*—The first direct experiments on fluid friction were made by Coulomb, who employed a circular disk suspended by a thin brass wire and oscillated in its own plane. His experiments were chiefly made at very low velocities. When the disk is rotated to any given angle, it oscillates under the action of its inertia and the torsion of the wire. The oscillations diminish gradually in consequence of the work done in overcoming the friction of the disk. The diminution furnishes a means of determining the friction.

Fig. 78 shows Coulomb's apparatus. LK supports the wire and disk; *ag* is the brass wire, the torsion of which causes the oscillations; DS is a graduated disk serving to measure the angles through which the apparatus oscillates. To this the friction disk is rigidly attached hanging in a vessel of water. The friction disks were from 4·7 to 7·7 in. diameter, and they generally made one oscillation in from 20 to 30 seconds, through angles varying from 360° to 6°. When the velocity of the circumference of the disk was less than 6 in. per second, the resistance was sensibly proportional to the velocity.

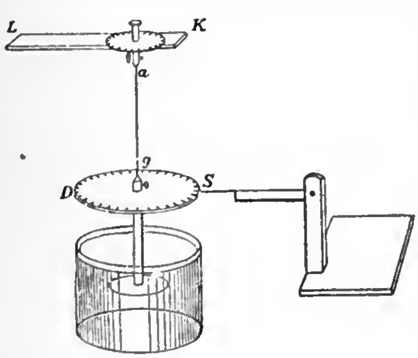

FIG. 78.

Beaufoy's Experiments.—Towards the end of the 18th century Colonel Mark Beaufoy (1764–1827) made an immense mass of experiments on the resistance of bodies moved through water (*Nautical and Hydraulic Experiments*, London, 1834). Of these the only ones directly bearing on surface friction were some made in 1796 and 1798. Smooth painted planks were drawn through water and the resistance measured. For two planks differing in area by 46 sq. ft., at a velocity of 10 ft. per second, the difference of resistance, measured on the difference of area, was 0·339 lb per square foot. Also the resistance varied as the 1·949th power of the velocity.

§ 68. *Froude's Experiments.*—The most important direct experiments on fluid friction at ordinary velocities are those made by William Froude (1810–1879) at Torquay. The method adopted in these experiments was to tow a board in a still water canal, the velocity and the resistance being registered by very ingenious recording arrangements. The general arrangement of the apparatus is shown in fig. 79. AA is the board the resistance of which is to be determined. B is a cut-water giving a fine entrance to the plane surfaces of the board. CC is a bar to which the board AA is attached, and which is suspended by a parallel motion from a carriage running on rails above the still water canal. G is a link by which the resistance of the board is transmitted to a spiral spring H. A bar I rigidly connects the other end of the spring to the carriage. The dotted lines K, L indicate the position of a couple of levers by which the extension of the spring is caused to move a pen M, which records the extension on a greatly increased scale, by a line drawn on the paper cylinder N. This cylinder revolves at a speed proportionate to that of the carriage, its motion being obtained from the axle of the carriage wheels. A second pen O, receiving jerks at every second and a quarter from a clock P, records time on the paper cylinder. The scale for the line of resistance is ascertained by stretching the spiral spring by known weights. The boards used for the experiment

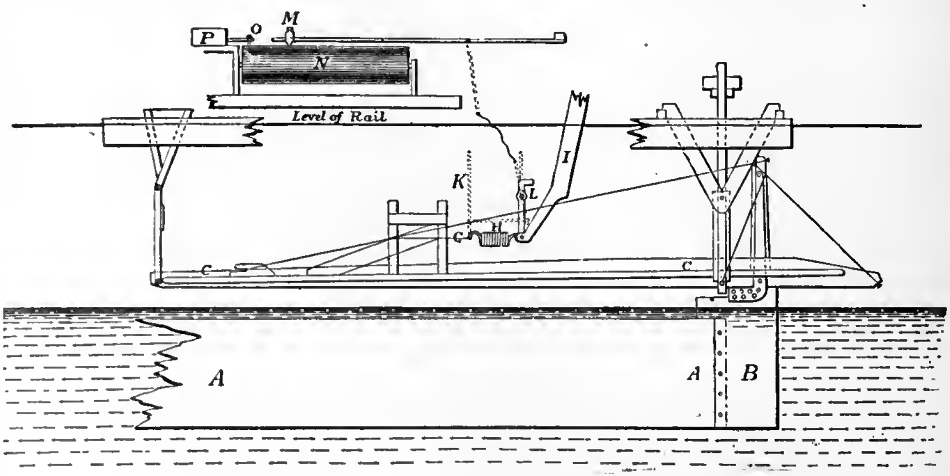

FIG. 79.

were $\frac{3}{16}$ in. thick, 19 in. deep, and from 1 to 50 ft. in length, cutwater included. A lead keel counteracted the buoyancy of the board. The boards were covered with various substances, such as paint, varnish, Hay's composition, tinfoil, &c., so as to try the effect of different degrees of roughness of surface. The results obtained by Froude may be summarized as follows:—

1. The friction per square foot of surface varies very greatly for different surfaces, being generally greater as the sensible roughness of the surface is greater. Thus, when the surface of the board was covered as mentioned below, the resistance for boards 50 ft. long, at 10 ft. per second, was—

Tinfoil or varnish	0·25 lb per sq. ft.
Calico	0·47 ,, ,,
Fine sand	0·405 ,, ,,
Coarser sand	0·488 ,, ,,

2. The power of the velocity to which the friction is proportional varies for different surfaces. Thus, with short boards 2 ft. long,

For tinfoil the resistance varied as $v^{2\cdot16}$.
For other surfaces the resistance varied as $v^{2\cdot00}$.

With boards 50 ft. long,

For varnish or tinfoil the resistance varied as $v^{1\cdot83}$.
For sand the resistance varied as $v^{2\cdot00}$.

3. The average resistance per square foot of surface was much greater for short than for long boards; or, what is the same thing, the resistance per square foot at the forward part of the board was greater than the friction per square foot of portions more sternward. Thus,

		Mean Resistance in lb per sq. ft.
Varnished surface . .	2 ft. long	0·41
	50 ,,	0·25
Fine sand surface . .	2 ,,	0·81
	50 ,,	0·405

This remarkable result is explained thus by Froude: "The portion of surface that goes first in the line of motion, in experiencing resistance from the water, must in turn communicate motion to the water, in the direction in which it is itself travelling. Consequently the portion of surface which succeeds the first will be rubbing, not against stationary water, but against water partially moving in its own direction, and cannot therefore experience so much resistance from it."

§ 69. The following table gives a general statement of Froude's results. In all the experiments in this table, the boards had a fine cutwater and a fine stern end or run, so that the resistance was entirely due to the surface. The table gives the resistances per square foot in pounds, at the standard speed of 600 feet per minute, and the power of the speed to which the friction is proportional, so that the resistance at other speeds is easily calculated.

	Length of Surface, or Distance from Cutwater, in feet.											
	2 ft.			8 ft.			20 ft.			50 ft.		
	A	B	C	A	B	C	A	B	C	A	B	C
Varnish	2·00	·41	·390	1·85	·325	·264	1·85	·278	·240	1·83	·250	·226
Paraffin	..	·38	·370	1·94	·314	·260	1·93	·271	·237	..	..	..
Tinfoil	2·16	·30	·295	1·99	·278	·263	1·90	·262	·244	1·83	·246	·232
Calico	1·93	·87	·725	1·92	·626	·504	1·89	·531	·447	1·87	·474	·423
Fine sand	2·00	·81	·690	2·00	·583	·450	2·00	·480	·384	2·06	·405	·337
Medium sand	2·00	·90	·730	2·00	·625	·488	2·00	·534	·465	2·00	·488	·456
Coarse sand	2·00	1·10	·880	2·00	·714	·520	2·00	·588	·490	..	..	..

Columns A give the power of the speed to which the resistance is approximately proportional.

Columns B give the mean resistance per square foot of the whole surface of a board of the lengths stated in the table.

Columns C give the resistance in pounds of a square foot of surface at the distance sternward from the cutwater stated in the heading.

Although these experiments do not directly deal with surfaces of greater length than 50 ft., they indicate what would be the resistances of longer surfaces. For at 50 ft. the decrease of resistance for an increase of length is so small that it will make no very great difference in the estimate of the friction whether we suppose it to continue to diminish at the same rate or not to diminish at all. For a varnished surface the friction at 10 ft. per second diminishes from 0·41 to 0·32 ℔ per square foot when the length is increased from 2 to 8 ft., but it only diminishes from 0·278 to 0·250 ℔ per square foot for an increase from 20 ft. to 50 ft.

If the decrease of friction sternwards is due to the generation of a current accompanying the moving plane, there is not at first sight any reason why the decrease should not be greater than that shown by the experiments. The current accompanying the board might be assumed to gain in volume and velocity sternwards, till the velocity was nearly the same as that of the moving plane and the friction per square foot nearly zero. That this does not happen appears to be due to the mixing up of the current with the still water surrounding it. Part of the water in contact with the board at any point, and receiving energy of motion from it, passes afterwards to distant regions of still water, and portions of still water are fed in towards the board to take its place. In the forward part of the board more kinetic energy is given to the current than is diffused into surrounding space, and the current gains in velocity. At a greater distance back there is an approximate balance between the energy communicated to the water and that diffused. The velocity of the current accompanying the board becomes constant or nearly constant, and the friction per square foot is therefore nearly constant also.

§ 70. *Friction of Rotating Disks.*—A rotating disk is virtually a surface of unlimited extent and it is convenient for experiments on friction with different surfaces at different speeds. Experiments carried out by Professor W. C. Unwin (*Proc. Inst. Civ. Eng.* lxxx.) are useful both as illustrating the laws of fluid friction and as giving data for calculating the resistance of the disks of turbines and centrifugal pumps. Disks of 10, 15 and 20 in. diameter fixed on a vertical shaft were rotated by a belt driven by an engine. They were enclosed in a cistern of water between parallel top and bottom fixed surfaces. The cistern was suspended by three fine wires. The friction of the disk is equal to the tendency of the cistern to rotate, and this was measured by balancing the cistern by a fine silk cord passing over a pulley and carrying a scale pan in which weights could be placed.

If ω is an element of area on the disk moving with the velocity v, the friction on this element is $f\omega v^n$, where f and n are constant for any given kind of surface. Let α be the angular velocity of rotation, R the radius of the disk. Consider a ring of the surface between r and $r+dr$. Its area is $2\pi r dr$, its velocity αr and the friction of this ring is $f 2\pi r dr \alpha^n r^n$. The moment of the friction about the axis of rotation is $2\pi\alpha^n f r^{n+2} dr$, and the total moment of friction for the two sides of the disk is

$$M = 4\pi\alpha^n f \int_0^R r^{n+2} dr = \{4\pi\alpha^n/(n+3)\} f R^{n+3}.$$

If N is the number of revolutions per sec.,

$$M = \{2^{n+2}\pi^{n+1} N^n/(n+3)\} f R^{n+3},$$

and the work expended in rotating the disk is

$$M\alpha = \{2^{n+3}\pi^{n+2} N^{n+1}/(n+3)\} f R^{n+3} \text{ foot ℔ per sec.}$$

The experiments give directly the values of M for the disks corresponding to any speed N. From these the values of f and n can be deduced, f being the friction per square foot at unit velocity. For comparison with Froude's results it is convenient to calculate the resistance at 10 ft. per second, which is $F = f 10^n$.

The disks were rotated in chambers 22 in. diameter and 3, 6 and 12 in. deep. In all cases the friction of the disks increased a little as the chamber was made larger. This is probably due to the stilling of the eddies against the surface of the chamber and the feeding back of the stilled water to the disk. Hence the friction depends not only on the surface of the disk but to some extent on the surface of the chamber in which it rotates. If the surface of the chamber is made rougher by covering with coarse sand there is also an increase of resistance.

For the smoother surfaces the friction varied as the 1·85th power of the velocity. For the rougher surfaces the power of the velocity to which the resistance was proportional varied from 1·9 to 2·1. This is in agreement with Froude's results.

Experiments with a bright brass disk showed that the friction decreased with increase of temperature. The diminution between 41° and 130° F. amounted to 18%. In the general equation $M = cN^n$ for any given disk,

$$c_t = 0{\cdot}1328(1 - 0{\cdot}0021t),$$

where c_t is the value of c for a bright brass disk 0·85 ft. in diameter at a temperature t° F.

The disks used were either polished or made rougher by varnish or by varnish and sand. The following table gives a comparison of the results obtained with the disks and Froude's results on planks 50 ft. long. The values given are the resistances per square foot at 10 ft. per sec.

Froude's Experiments.		*Disk Experiments.*	
Tinfoil surface	0·232	Bright brass	0·202 to 0·229
Varnish	0·226	Varnish	0·220 to 0·233
Fine sand	0·337	Fine sand	0·339
Medium sand	0·456	Very coarse sand	0·587 to 0·715

VIII. STEADY FLOW OF WATER IN PIPES OF UNIFORM SECTION.

§ 71. The ordinary theory of the flow of water in pipes, on which all practical formulae are based, assumes that the variation of velocity at different points of any cross section may be neglected. The water is considered as moving in plane layers, which are driven through the pipe against the frictional resistance, by the difference of pressure at or elevation of the ends of the pipe. If the motion is steady the velocity at each cross section remains the same from moment to moment, and if the cross sectional area is constant the velocity at all sections must be the same. Hence the motion is uniform. The most important resistance to the motion of the water is the surface friction of the pipe, and it is convenient to estimate this independently of some smaller resistances which will be accounted for presently.

In any portion of a uniform pipe, excluding for the present the ends of the pipe, the water enters and leaves at the same velocity. For that portion therefore the work of the external forces and of the surface friction must be equal. Let fig. 80 represent a very short portion of the pipe, of length dl, between cross sections at z and $z+dz$ ft. above any horizontal datum line xx, the pressures at the cross sections being p and $p+dp$ ℔ per square foot. Further, let Q be the volume of flow or discharge of the pipe per second, Ω the area of a normal cross section, and χ the perimeter of the pipe. The Q cubic feet, which flow through the space considered per second, weigh GQ ℔, and fall through a height $-dz$ ft. The work done by gravity is then

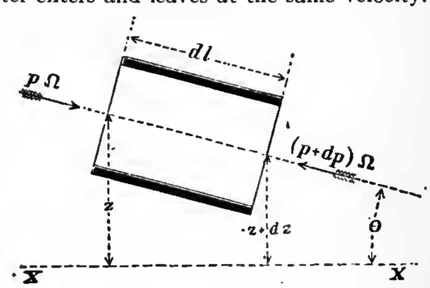

Fig. 80.

$$-GQdz;$$

a positive quantity if dz is negative, and vice versa. The resultant pressure parallel to the axis of the pipe is $p-(p+dp) = -dp$ ℔ per square foot of the cross section. The work of this pressure on the volume Q is

$$-Qdp.$$

The only remaining force doing work on the system is the friction against the surface of the pipe. The area of that surface is $\chi\, dl$.

The work expended in overcoming the frictional resistance per second is (see § 66, eq. 3)

$$-\zeta G\chi dl v^3/2g,$$

or, since $Q = \Omega v$,

$$-\zeta G(\chi/\Omega)Q(v^2/2g)dl;$$

the negative sign being taken because the work is done against a resistance. Adding all these portions of work, and equating the result to zero, since the motion is uniform,—

$$-GQdz - Qdp - \zeta G(\chi/\Omega)Q(v^2/2g)dl = 0.$$

Dividing by GQ,

$$dz + dp/G + \zeta(\chi/\Omega)(v^2/2g)dl = 0.$$

Integrating,

$$z + p/G + \zeta(\chi/\Omega)(v^2/2g)l = \text{constant}. \qquad (1)$$

§ 72. Let A and B (fig. 81) be any two sections of the pipe for which p, z, l have the values p_1, z_1, l_1, and p_2, z_2, l_2, respectively. Then

$$z_1 + p_1/G + \zeta(\chi/\Omega)(v^2/2g)l_1 = z_2 + p_2/G + \zeta(\chi/\Omega)(v^2/2g)l_2;$$

or, if $l_2 - l_1 = L$, rearranging the terms,

$$\zeta v^2/2g = (1/L)\{(z_1 + p_1/G) - (z_2 + p_2/G)\}\Omega/\chi. \qquad (2)$$

Suppose pressure columns introduced at A and B. The water will rise in those columns to the heights p_1/G and p_2/G due to the

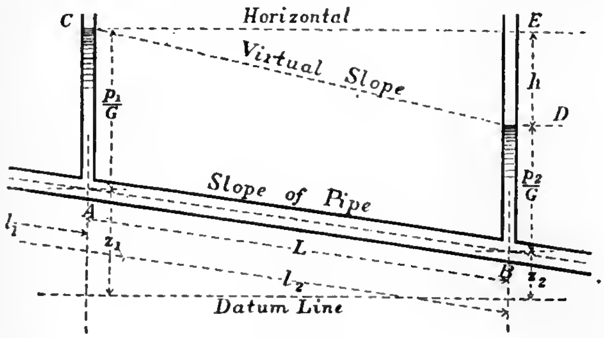

FIG. 81.

pressures p_1 and p_2 at A and B. Hence $(z_1 + p_1/G) - (z_2 + p_2/G)$ is the quantity represented in the figure by DE, the fall of level of the pressure columns, or *virtual fall* of the pipe. If there were no friction in the pipe, then by Bernoulli's equation there would be no fall of level of the pressure columns, the velocity being the same at A and B. Hence DE or h is the head lost in friction in the distance AB. The quantity $DE/AB = h/L$ is termed the virtual slope of the pipe or virtual fall per foot of length. It is sometimes termed very conveniently the relative fall. It will be denoted by the symbol i.

The quantity Ω/χ which appears in many hydraulic equations is called the hydraulic mean radius of the pipe. It will be denoted by m.

Introducing these values,

$$\zeta v^2/2g = mh/L = mi. \qquad (3)$$

For pipes of circular section, and diameter d,

$$m = \Omega/\chi = \tfrac{1}{4}\pi d^2/\pi d = \tfrac{1}{4}d.$$

Then
$$\zeta v^2/2g = \tfrac{1}{4}dh/L = \tfrac{1}{4}di; \qquad (4)$$

or
$$h = \zeta(4L/d)(v^2/2g); \qquad (4a)$$

which shows that the head lost in friction is proportional to the head due to the velocity, and is found by multiplying that head by the coefficient $4\zeta L/d$. It is assumed above that the atmospheric pressure at C and D is the same, and this is usually nearly the case. But if C and D are at greatly different levels the excess of barometric pressure at C, in feet of water, must be added to p_2/G.

§ 73. *Hydraulic Gradient or Line of Virtual Slope.*—Join CD. Since the head lost in friction is proportional to L, any intermediate pressure column between A and B will have its free surface on the line CD, and the vertical distance between CD and the pipe at any point measures the pressure, exclusive of atmospheric pressure, in the pipe at that point. If the pipe were laid along the line CD instead of AB, the water would flow at the same velocity by gravity without any change of pressure from section to section. Hence CD is termed the virtual slope or hydraulic gradient of the pipe. It is the line of free surface level for each point of the pipe.

If an ordinary pipe, connecting reservoirs open to the air, rises at any joint above the line of virtual slope, the pressure at that point is less than the atmospheric pressure transmitted through the pipe. At such a point there is a liability that air may be disengaged from the water, and the flow stopped or impeded by the accumulation of air. If the pipe rises more than 34 ft. above the line of virtual slope, the pressure is negative. But as this is impossible, the continuity of the flow will be broken.

If the pipe is not straight, the line of virtual slope becomes a curved line, but since in actual pipes the vertical alterations of level are generally small, compared with the length of the pipe, distances measured along the pipe are sensibly proportional to distances measured along the horizontal projection of the pipe. Hence the line of hydraulic gradient may be taken to be a straight line without error of practical importance.

§ 74. *Case of a Uniform Pipe connecting two Reservoirs, when all the Resistances are taken into account.*—Let h (fig. 82) be the difference of level of the reservoirs, and v the velocity, in a pipe of length L and diameter d. The whole work done per second is virtually the removal of Q cub. ft. of water from the surface of the upper reservoir to the surface of the lower reservoir, that is GQh foot-pounds. This is expended in three ways. (1) The head $v^2/2g$, corresponding to an expenditure of $GQv^2/2g$ foot-pounds of work, is employed in giving energy of motion to the water. This is ulti-

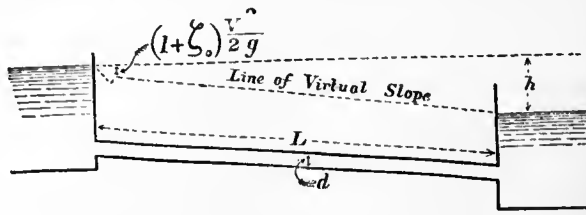

FIG. 82.

mately wasted in eddying motions in the lower reservoir. (2) A portion of head, which experience shows may be expressed in the form $\zeta_0 v^2/2g$, corresponding to an expenditure of $GQ\zeta_0 v^2/2g$ foot-pounds of work, is employed in overcoming the resistance at the entrance to the pipe. (3) As already shown the head expended in overcoming the surface friction of the pipe is $\zeta(4L/d)(v^2/2g)$ corresponding to $GQ\zeta(4L/d)(v^2/2g)$ foot-pounds of work. Hence

$$GQh = GQv^2/2g + GQ\zeta_0 v^2/2g + GQ\zeta.4L.v^2/d.2g;$$

$$\left.\begin{aligned} h &= (1 + \zeta_0 + \zeta\,.\,4L/d)v^2/2g. \\ v &= 8{\cdot}025\sqrt{[hd/\{(1+\zeta_0)d + 4\zeta L\}]}. \end{aligned}\right\} \qquad (5)$$

If the pipe is bellmouthed, ζ_0 is about $= {\cdot}08$. If the entrance to the pipe is cylindrical, $\zeta_0 = 0{\cdot}505$. Hence $1 + \zeta_0 = 1{\cdot}08$ to $1{\cdot}505$. In general this is so small compared with $\zeta 4L/d$ that, for practical calculations, it may be neglected; that is, the losses of head other than the loss in surface friction are left out of the reckoning. It is only in short pipes and at high velocities that it is necessary to take account of the first two terms in the bracket, as well as the third. For instance, in pipes for the supply of turbines, v is usually limited to 2 ft. per second, and the pipe is bellmouthed. Then $1{\cdot}08v^2/2g = 0{\cdot}067$ ft. In pipes for towns' supply v may range from 2 to $4\frac{1}{2}$ ft. per second, and then $1{\cdot}5v^2/2g = 0{\cdot}1$ to $0{\cdot}5$ ft. In either case this amount of head is small compared with the whole virtual fall in the cases which most commonly occur.

When d and v or d and h are given, the equations above are solved quite simply. When v and h are given and d is required, it is better to proceed by approximation. Find an approximate value of d by assuming a probable value for ζ as mentioned below. Then from that value of d find a corrected value for ζ and repeat the calculation.

The equation above may be put in the form

$$h = (4\zeta/d)[\{(1+\zeta_0)d/4\zeta\} + L]v^2/2g; \qquad (6)$$

from which it is clear that the head expended at the mouthpiece is equivalent to that of a length

$$(1+\zeta_0)d/4\zeta$$

of the pipe. Putting $1 + \zeta_0 = 1{\cdot}505$ and $\zeta = 0{\cdot}01$, the length of pipe equivalent to the mouthpiece is $37{\cdot}6\ d$ nearly. This may be added to the actual length of the pipe to allow for mouthpiece resistance in approximate calculations.

§ 75. *Coefficient of Friction for Pipes discharging Water.*—From the average of a large number of experiments, the value of ζ for ordinary iron pipes is

$$\zeta = 0{\cdot}007567. \qquad (7)$$

But practical experience shows that no single value can be taken applicable to very different cases. The earlier hydraulicians occupied themselves chiefly with the dependence of ζ on the velocity. Having regard to the difference of the law of resistance at very low and at ordinary velocities, they assumed that ζ might be expressed in the form

$$\zeta = \alpha + \beta/v.$$

The following are the best numerical values obtained for ζ so expressed:—

	α	β
R. de Prony (from 51 experiments) . . .	0·006836	0·001116
J. F. d'Aubuisson de Voisins	0·00673	0·001211
J. A. Eytelwein	0·005493	0·00143

Weisbach proposed the formula

$$4\zeta = \alpha + \beta/\sqrt{v} = 0{\cdot}003598 + 0{\cdot}004289/\sqrt{v}. \qquad (8)$$

§ 76. *Darcy's Experiments on Friction in Pipes.*—All previous experiments on the resistance of pipes were superseded by the remarkable researches carried out by H. P. G. Darcy (1803–1858), the Inspector-General of the Paris water works. His experiments were carried out on a scale, under a variation of conditions, and with a degree of accuracy which leaves little to be desired, and the results obtained are of very great practical importance. These results may be stated thus:—

1. For new and clean pipes the friction varies considerably with the nature and polish of the surface of the pipe. For clean cast iron it is about $1\frac{1}{2}$ times as great as for cast iron covered with pitch.

2. The nature of the surface has less influence when the pipes are old and incrusted with deposits, due to the action of the water. Thus old and incrusted pipes give twice as great a frictional resistance as new and clean pipes. Darcy's coefficients were chiefly determined from experiments on new pipes. He doubles these coefficients for old and incrusted pipes, in accordance with the results of a very limited number of experiments on pipes containing incrustations and deposits.

3. The coefficient of friction may be expressed in the form $\zeta=\alpha+\beta/v$; but in pipes which have been some time in use it is sufficiently accurate to take $\zeta=\alpha_1$ simply, where α_1 depends on the diameter of the pipe alone, but α and β on the other hand depend both on the diameter of the pipe and the nature of its surface. The following are the values of the constants.

For pipes which have been some time in use, neglecting the term depending on the velocity;

$$\zeta=\alpha(1+\beta/d). \qquad (9)$$

	α	β
For drawn wrought-iron or smooth cast-iron pipes	·004973	·084
For pipes altered by light incrustations . .	·00996	·084

These coefficients may be put in the following very simple form, without sensibly altering their value:—

$$\left.\begin{array}{ll}\text{For clean pipes . . . . .} & \zeta=\cdot005(1+1/12d)\\ \text{For slightly incrusted pipes .} & \zeta=\cdot01(1+1/12d)\end{array}\right\} \qquad (9a)$$

Darcy's Value of the Coefficient of Friction ζ for Velocities not less than 4 in. per second.

Diameter of Pipe in Inches.	ζ New Pipes.	ζ Incrusted Pipes.	Diameter of Pipe in Inches.	ζ New Pipes.	ζ Incrusted Pipes.
2	0·00750	0·01500	18	·00528	·01056
3	·00667	·01333	21	·00524	·01048
4	·00625	·01250	24	·00521	·01042
5	·00600	·01200	27	·00519	·01037
6	·00583	·01167	30	·00517	·01033
7	·00571	·01143	36	·00514	·01028
8	·00563	·01125	42	·00512	·01024
9	·00556	·01111	48	·00510	·01021
12	·00542	·01083	54	·00509	·01019
15	·00533	·01067			

These values of ζ are, however, not exact for widely differing velocities. To embrace all cases Darcy proposed the expression

$$\zeta=(\alpha+\alpha_1/d)+(\beta+\beta_1/d^2)/v; \qquad (10)$$

which is a modification of Coulomb's, including terms expressing the influence of the diameter and of the velocity. For clean pipes Darcy found these values

$$\begin{aligned}\alpha&=\cdot004346\\ \alpha_1&=\cdot0003992\\ \beta&=\cdot0010182\\ \beta_1&=\cdot000005205.\end{aligned}$$

It has become not uncommon to calculate the discharge of pipes by the formula of E. Ganguillet and W. R. Kutter, which will be discussed under the head of channels. For the value of c in the relation $v=c\sqrt{(mi)}$, Ganguillet and Kutter take

$$c=\frac{41\cdot6+1\cdot811/n+\cdot00281/i}{1+[(41\cdot6+\cdot00281/i)(n/\sqrt{m})]}$$

where n is a coefficient depending only on the roughness of the pipe. For pipes uncoated as ordinarily laid $n=0\cdot013$. The formula is very cumbrous, its form is not rationally justifiable and it is not at all clear that it gives more accurate values of the discharge than simpler formulae.

§ 77. *Later Investigations on Flow in Pipes.*—The foregoing statement gives the theory of flow in pipes so far as it can be put in a simple rational form. But the conditions of flow are really more complicated than can be expressed in any rational form. Taking even selected experiments the values of the empirical coefficient ζ range from 0·16 to 0·0028 in different cases. Hence means of discriminating the probable value of ζ are necessary in using the equations for practical purposes. To a certain extent the knowledge that ζ decreases with the size of the pipe and increases very much with the roughness of its surface is a guide, and Darcy's method of dealing with these causes of variation is very helpful. But a further difficulty arises from the discordance of the results of different experiments. For instance F. P. Stearns and J. M. Gale both experimented on clean asphalted cast-iron pipes, 4 ft. in diameter. According to one set of gaugings $\zeta=\cdot0051$, and according to the other $\zeta=\cdot0031$. It is impossible in such cases not to suspect some error in the observations or some difference in the condition of the pipes not noticed by the observers.

It is not likely that any formula can be found which will give exactly the discharge of any given pipe. For one of the chief factors in any such formula must express the exact roughness of the pipe surface, and there is no scientific measure of roughness. The most that can be done is to limit the choice of the coefficient for a pipe within certain comparatively narrow limits. The experiments on fluid friction show that the power of the velocity to which the resistance is proportional is not exactly the square. Also in determining the form of his equation for ζ Darcy used only eight out of his seventeen series of experiments, and there is reason to think that some of these were exceptional. Barré de Saint-Venant was the first to propose a formula with two constants,

$$dh/4l=mV^n,$$

where m and n are experimental constants. If this is written in the form

$$\log m+n\log v=\log(dh/4l),$$

we have, as Saint-Venant pointed out, the equation to a straight line, of which m is the ordinate at the origin and n the ratio of the slope. If a series of experimental values are plotted logarithmically the determination of the constants is reduced to finding the straight line which most nearly passes through the plotted points. Saint-Venant found for n the value of 1·71. In a memoir on the influence of temperature on the movement of water in pipes (Berlin, 1854) by G. H. L. Hagen (1797–1884) another modification of the Saint-Venant formula was given. This is $h/l=mv^n/d^x$, which involves three experimental coefficients. Hagen found $n=1\cdot75$; $x=1\cdot25$; and m was then nearly independent of variations of v and d. But the range of cases examined was small. In a remarkable paper in the *Trans. Roy. Soc.*, 1883, Professor Osborne Reynolds made much clearer the change from regular stream line motion at low velocities to the eddying motion, which occurs in almost all the cases with which the engineer has to deal. Partly by reasoning, partly by induction from the form of logarithmically plotted curves of experimental results, he arrived at the general equation $h/l=c(v^n/d^{3-n})P^{2-n}$, where $n=1$ for low velocities and $n=1\cdot7$ to 2 for ordinary velocities. P is a function of the temperature. Neglecting variations of temperature Reynold's formula is identical with Hagen's if $x=3-n$. For practical purposes Hagen's form is the more convenient.

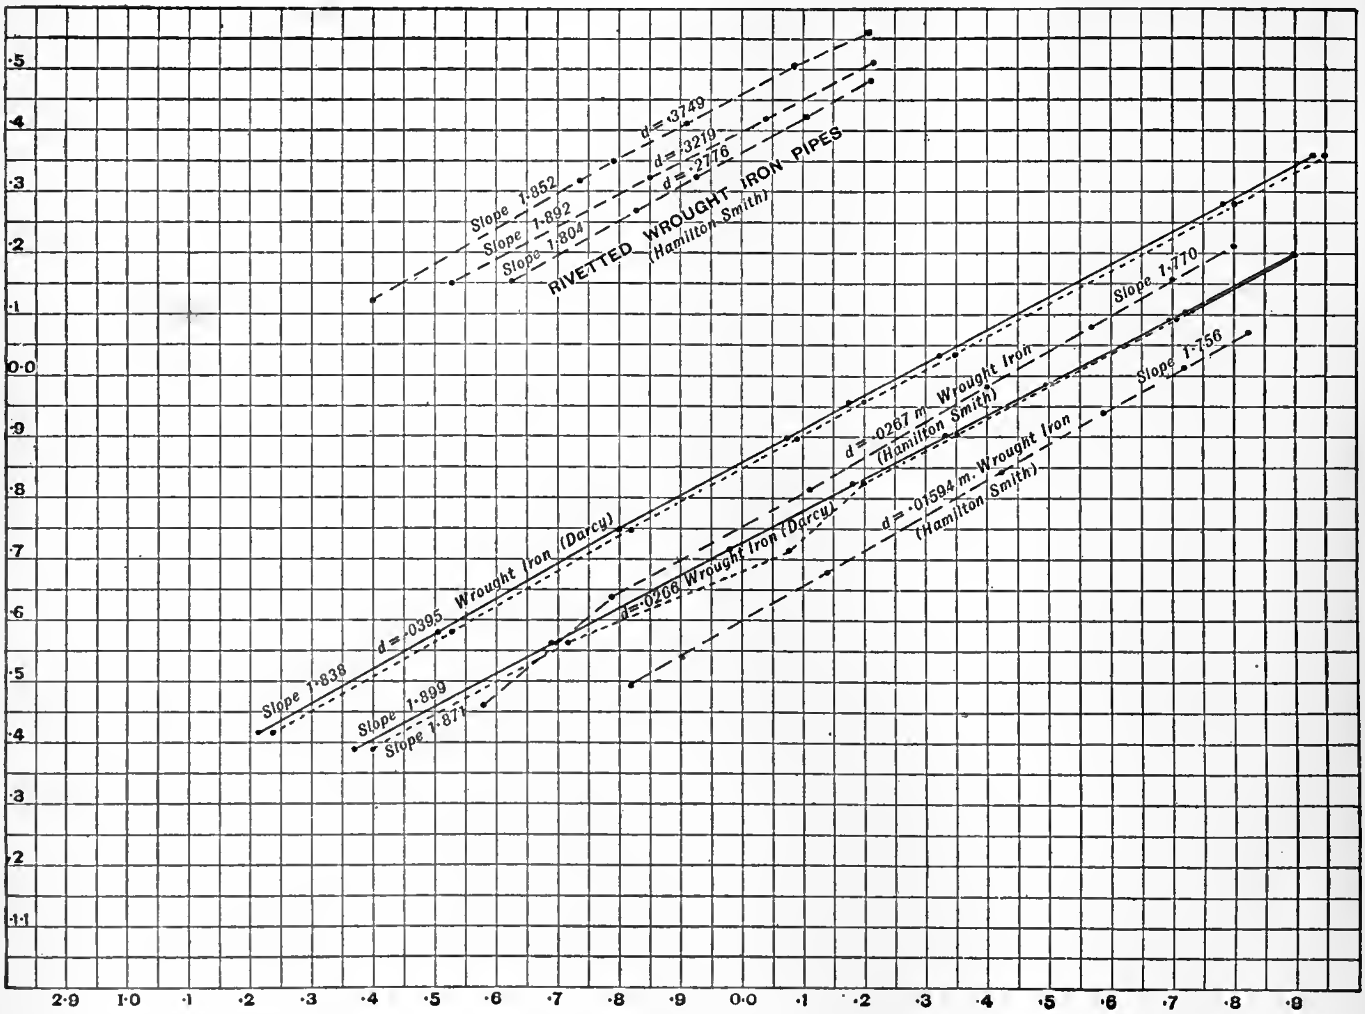

FIG. 83.

In 1886, Professor W. C. Unwin plotted logarithmically all the most trustworthy experiments on flow in pipes then available.[1] Fig. 83 gives one such plotting. The results of measuring the slopes of the lines drawn through the plotted points are given in the table.

It will be seen that the values of the index n range from 1·72 for the smoothest and cleanest surface, to 2·00 for the roughest. The numbers after the brackets are rounded off numbers.

The value of n having been thus determined, values of m/d^x were next found and averaged for each pipe. These were again plotted logarithmically in order to find a value for x. The lines were not very regular, but in all cases the slope was greater than 1 to 1, so that the value of x must be greater than unity. The following table gives the results and a comparison of the value of x and Reynolds's value $3-n$.

Kind of Pipe.	n	$3-n$	x
Tin plate	1·72	1·28	1·100
Wrought iron (Smith)	1·75	1·25	1·210
Asphalted pipes	1·85	1·15	1·127
Wrought iron (Darcy)	1·87	1·13	1·680
Riveted wrought iron	1·87	1·13	1·390
New cast iron	1·95	1·05	1·168
Cleaned cast iron	2·00	1·00	1·168
Incrusted cast iron	2·00	1·00	1·160

With the exception of the anomalous values for Darcy's wrought-iron pipes, there is no great discrepancy between the values of x and $3-n$, but there is no appearance of relation in the two quantities. For the present it appears preferable to assume that x is independent of n.

It is now possible to obtain values of the third constant m, using the values found for n and x. The following table gives the results, the values of m being for metric measures.

[1] "Formulae for the Flow of Water in Pipes," *Industries* (Manchester, 1886).

Here, considering the great range of diameters and velocities in the experiments, the constancy of m is very satisfactorily close. The asphalted pipes give rather variable values. But, as some of these were new and some old, the variation is, perhaps, not surprising. The incrusted pipes give a value of m quite double that for new pipes but that is perfectly consistent with what is known of fluid friction in other cases.

Kind of Pipe.	Diameter in Metres.	Value of m.	Mean Value of m.	Authority.

General Mean Values of Constants.

The general formula (Hagen's)—$h/l = mv^n/d^x.2g$—can therefore be taken to fit the results with convenient closeness, if the following mean values of the coefficients are taken, the unit being a metre:—

Kind of Pipe.	m	x	n
Tin plate	·0169	1·10	1·72
Wrought iron . . .	·0131	1·21	1·75
Asphalted iron . . .	·0183	1·127	1·85
Riveted wrought iron .	·0140	1·390	1·87
New cast iron . . .	·0166	1·168	1·95
Cleaned cast iron . .	·0199	1·168	2·0
Incrusted cast iron .	·0364	1·160	2·0

The variation of each of these coefficients is within a comparatively narrow range, and the selection of the proper coefficient for any given case presents no difficulty, if the character of the surface of the pipe is known.

It only remains to give the values of these coefficients when the quantities are expressed in English feet. For English measures the following are the values of the coefficients:—

Kind of Pipe.	m	x	n
Tin plate	·0265	1·10	1·72
Wrought iron . . .	·0226	1·21	1·75
Asphalted iron . . .	·0254	1·127	1·85
Riveted wrought iron .	·0260	1·390	1·87
New cast iron . . .	·0215	1·168	1·95
Cleaned cast iron . .	·0243	1·168	2·0
Incrusted cast iron .	·0440	1·160	2·0

§ 78. *Distribution of Velocity in the Cross Section of a Pipe.*—Darcy made experiments with a Pitot tube in 1850 on the velocity at different points in the cross section of a pipe. He deduced the relation

$$V - v = 11{\cdot}3(r^{\frac{3}{2}}/R)\sqrt{i},$$

where V is the velocity at the centre and v the velocity at radius r in a pipe of radius R with a hydraulic gradient i. Later Bazin repeated the experiments and extended them (*Mém. de l'Académie des Sciences*, xxxii. No. 6). The most important result was the ratio of mean to central velocity. Let $b = Ri/U^2$, where U is the mean velocity in the pipe; then $V/U = 1 + 9{\cdot}03\sqrt{b}$. A very useful result for practical purposes is that at 0·74 of the radius of the pipe the velocity is equal to the mean velocity. Fig. 84 gives the velocities at different radii as determined by Bazin.

§ 79. *Influence of Temperature on the Flow through Pipes.*—Very careful experiments on the flow through a pipe 0·1236 ft. in diameter

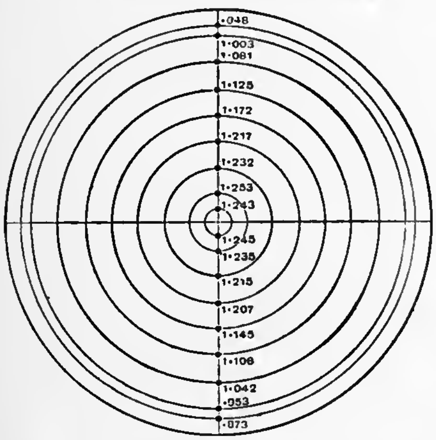

Fig. 84.

and 25 ft. long, with water at different temperatures, have been made by J. G. Mair (*Proc. Inst. Civ. Eng.* lxxxiv.). The loss of head was measured from a point 1 ft. from the inlet, so that the loss at entry was eliminated. The 1½ in. pipe was made smooth inside and to gauge, by drawing a mandril through it. Plotting the results logarithmically, it was found that the resistance for all temperatures varied very exactly as $v^{1{\cdot}795}$, the index being less than 2 as in other experiments with very smooth surfaces. Taking the ordinary equation of flow $h = \zeta(4L/D)(v^2/2g)$, then for heads varying from 1 ft. to nearly 4 ft., and velocities in the pipe varying from 4 ft. to 9 ft. per second, the values of ζ were as follows:—

Temp. F.	ζ	Temp. F.	ζ
57	·0044 to ·0052	100	·0039 to ·0042
70	·0042 to ·0045	110	·0037 to ·0041
80	·0041 to ·0045	120	·0037 to ·0041
90	·0040 to ·0045	130	·0035 to ·0039
		160	·0035 to ·0038

This shows a marked decrease of resistance as the temperature rises. If Professor Osborne Reynolds's equation is assumed $h = mLV^n/d^{3-n}$, and n is taken 1·795, then values of m at each temperature are practically constant—

Temp. F.	m.	Temp. F.	m.
57	0·000276	100	0·000244
70	0·000263	110	0·000235
80	0·000257	120	0·000229
90	0·000250	130	0·000225
		160	0·000206

where again a regular decrease of the coefficient occurs as the temperature rises. In experiments on the friction of disks at different temperatures Professor W. C. Unwin found that the resistance was proportional to constant $\times (1 - 0{\cdot}0021t)$ and the values of m given above are expressed almost exactly by the relation

$$m = 0{\cdot}000311(1 - 0{\cdot}00215\,t).$$

In tank experiments on ship models for small ordinary variations of temperature, it is usual to allow a decrease of 3% of resistance for 10° F. increase of temperature.

§ 80. *Influence of Deposits in Pipes on the Discharge. Scraping Water Mains.*—The influence of the condition of the surface of a pipe on the friction is shown by various facts known to the engineers of waterworks. In pipes which convey certain kinds of water, oxidation proceeds rapidly and the discharge is considerably diminished. A main laid at Torquay in 1858, 14 m. in length, consists of 10-in., 9-in. and 8-in. pipes. It was not protected from corrosion by any coating. But it was found to the surprise of the engineer that in eight years the discharge had diminished to 51% of the original discharge. J. G. Appold suggested an apparatus for scraping the interior of the pipe, and this was constructed and used under the direction of William Froude (see "Incrustation of Iron Pipes," by W. Ingham, *Proc. Inst. Mech. Eng.*, 1899). It was found that by scraping the interior of the pipe the discharge was increased 56%. The scraping requires to be repeated at intervals. After each scraping the discharge diminishes rather rapidly to 10% and afterwards more slowly, the diminution in a year being about 25%.

Fig. 85 shows a scraper for water mains, similar to Appold's but modified in details, as constructed by the Glenfield Company, at Kilmarnock. A is a longitudinal section of the pipe, showing the scraper in place; B is an end view of the plungers, and C, D sections of the boxes placed at intervals on the main for introducing or withdrawing the scraper. The apparatus consists of two plungers, packed with leather so as to fit the main pretty closely. On the spindle of these plungers are fixed eight steel scraping blades, with curved scraping edges fitting the surface of the main. The apparatus is placed in the main by removing the cover from one of the boxes shown at C, D. The cover is then replaced, water pressure is admitted behind the plungers, and the apparatus driven through the

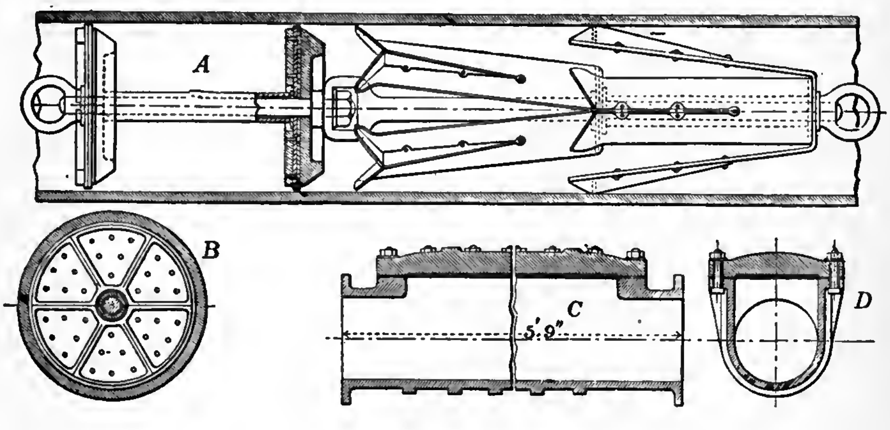

Fig. 85. Scale $\frac{1}{25}$.

main. At Lancaster after twice scraping the discharge was increased 56½%, at Oswestry 54½%. The increased discharge is due to the diminution of the friction of the pipe by removing the roughnesses due to oxidation. The scraper can be easily followed when the mains are about 3 ft. deep by the noise it makes. The average speed of the scraper at Torquay is 2⅓ m. per hour. At Torquay 49% of the deposit is iron rust, the rest being silica, lime and organic matter.

In the opinion of some engineers it is inadvisable to use the scraper. The incrustation is only temporarily removed, and if the use of the scraper is continued the life of the pipe is reduced. The only treatment effective in preventing or retarding the incrustation due to corrosion is to coat the pipes when hot with a smooth and perfect layer of pitch. With certain waters such as those derived from the chalk the incrustation is of a different character, consisting of nearly pure calcium carbonate. A deposit of another character which has led to trouble in some mains is a black slime containing a good deal of iron not derived from the pipes. It appears to be an organic growth. Filtration of the water appears to prevent the growth of the slime, and its temporary removal may be effected by a kind of brush scraper devised by G. F. Deacon (see "Deposits in Pipes," by Professor J. C. Campbell Brown, *Proc. Inst. Civ. Eng.*, 1903–1904).

§ 81. *Flow of Water through Fire Hose.*—The hose pipes used for fire purposes are of very varied character, and the roughness of the surface varies. Very careful experiments have been made by J. R. Freeman (*Am. Soc. Civ. Eng.* xxi., 1889). It was noted that under pressure the diameter of the hose increased sufficiently to have a marked influence on the discharge. In reducing the results the true diameter has been taken. Let v = mean velocity in ft. per sec.; r = hydraulic mean radius or one-fourth the diameter in feet; i = hydraulic gradient. Then $v = n\sqrt{(ri)}$.

§ 82. *Reduction of a Long Pipe of Varying Diameter to an Equivalent Pipe of Uniform Diameter. Dupuit's Equation.*—Water mains for the supply of towns often consist of a series of lengths, the diameter being the same for each length, but differing from length to length. In approximate calculations of the head lost in such mains, it is generally accurate enough to neglect the smaller losses of head and to have regard to the pipe friction only, and then the calculations may be facilitated by reducing the main to a main of uniform diameter, in which there would be the same loss of head. Such a uniform main will be termed an equivalent main.

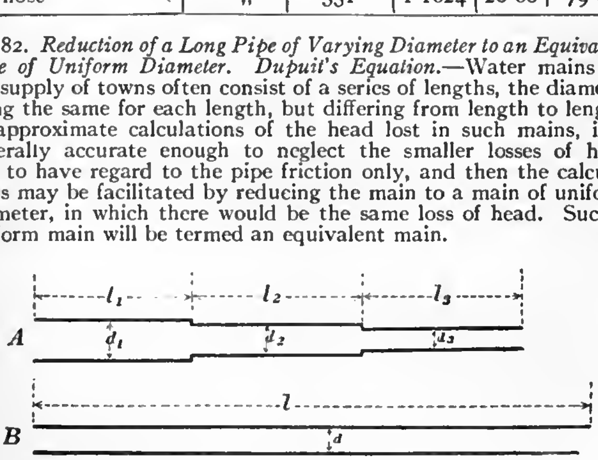

FIG. 86.

In fig. 86 let A be the main of variable diameter, and B the equivalent uniform main. In the given main of variable diameter A, let

$l_1, l_2 \ldots$ be the lengths,
$d_1, d_2 \ldots$ the diameters,
$v_1, v_2 \ldots$ the velocities,
$i_1, i_2 \ldots$ the slopes,

for the successive portions, and let l, d, v and i be corresponding quantities for the equivalent uniform main B. The total loss of head in A due to friction is

$$h = i_1 l_1 + i_2 l_2 + \ldots$$
$$= \zeta(v_1^2 \cdot 4l_1/2gd_1) + \zeta(v_2^2 \cdot 4l_2/2gd_2) + \ldots$$

and in the uniform main

$$il = \zeta(v^2 \cdot 4l/2gd).$$

If the mains are equivalent, as defined above,

$$\zeta(v^2 \cdot 4l/2gd) = \zeta(v_1^2 \cdot 4l_1/2gd_1) + \zeta(v_2^2 \cdot 4l_2/2gd_2) + \ldots$$

But, since the discharge is the same for all portions,

$$\tfrac{1}{4}\pi d^2 v = \tfrac{1}{4}\pi d_1^2 v_1 = \tfrac{1}{4}\pi d_2^2 v_2 = \ldots$$
$$v_1 = vd^2/d_1^2;\ v_2 = vd^2/d_2^2 \ldots$$

Also suppose that ζ may be treated as constant for all the pipes. Then

$$l/d = (d^4/d_1^4)(l_1/d_1) + (d^4/d_2^4)(l_2/d_2) + \ldots$$
$$l = (d^5/d_1^5)l_1 + (d^5/d_2^5)l_2 + \ldots$$

which gives the length of the equivalent uniform main which would have the same total loss of head for any given discharge.

§ 83. *Other Losses of Head in Pipes.*—Most of the losses of head in pipes, other than that due to surface friction against the pipe, are due to abrupt changes in the velocity of the stream producing eddies. The kinetic energy of these is deducted from the general energy of translation, and practically wasted.

Sudden Enlargement of Section.—Suppose a pipe enlarges in section from an area ω_0 to an area ω_1 (fig. 87); then

$$v_1/v_0 = \omega_0/\omega_1;$$

or, if the section is circular,

$$v_1/v_0 = (d_0/d_1)^2.$$

The head lost at the abrupt change of velocity has already been shown to be the head due to the relative velocity of the two parts of the stream. Hence head lost

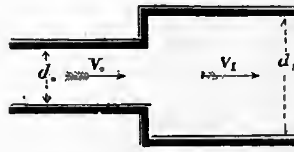

FIG. 87.

$$\mathfrak{h}_e = (v_0 - v_1)^2/2g = (\omega_1/\omega_0 - 1)^2 v_1^2/2g = \{(d_1/d_0)^2 - 1\}^2 v_1^2/2g$$

or $$\mathfrak{h}_e = \zeta_e v_1^2/2g, \quad (1)$$

if ζ_e is put for the expression in brackets.

$\omega_1/\omega_0 =$	1.1	1.2	1.5	1.7	1.8	1.9	2.0	2.5	3.0	3.5	4.0	5.0	6.0	7.0	8.0
$d_1/d_0 =$	1.05	1.10	1.22	1.30	1.34	1.38	1.41	1.58	1.73	1.87	2.00	2.24	2.45	2.65	2.83
$\zeta_e =$	.01	.04	.25	.49	.64	.81	1.00	2.25	4.00	6.25	9.00	16.00	25.00	36.0	49.0

Abrupt Contraction of Section.—When water passes from a larger to a smaller section, as in figs. 88, 89, a contraction is formed, and the contracted stream abruptly expands to fill the section of the pipe.

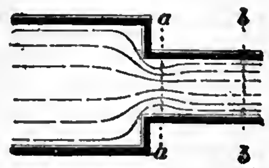

FIG. 88.

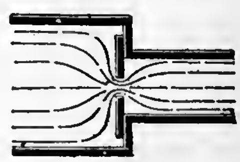

FIG. 89.

Let ω be the section and v the velocity of the stream at bb. At aa the section will be $c_c\omega$, and the velocity $(\omega/c_c\omega)v = v/c_1$, where c_c is the coefficient of contraction. Then the head lost is

$$\mathfrak{h}_m = (v/c_c - v)^2/2g = (1/c_c - 1)^2 v^2/2g;$$

and, if c_c is taken 0·64,

$$\mathfrak{h}_m = 0{\cdot}316\, v^2/2g. \quad (2)$$

The value of the coefficient of contraction for this case is, however, not well ascertained, and the result is somewhat modified by friction. For water entering a cylindrical, not bell-mouthed, pipe from a reservoir of indefinitely large size, experiment gives

$$\mathfrak{h}_a = 0{\cdot}505\, v^2/2g. \quad (3)$$

If there is a diaphragm at the mouth of the pipe as in fig. 89, let ω_1 be the area of this orifice. Then the area of the contracted stream is $c_c\omega_1$, and the head lost is

$$\mathfrak{h}_c = \{(\omega/c_c\omega_1) - 1\}^2 v^2/2g$$
$$= \zeta_c v^2/2g \quad (4)$$

if ζ_c is put for $\{(\omega/c_c\omega_1) - 1\}^2$. Weisbach has found experimentally the following values of the coefficient, when the stream approaching the orifice was considerably larger than the orifice:—

$\omega_1/\omega =$	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
$c_c =$	.616	.614	.612	.610	.617	.605	.603	.601	.598	.596
$\zeta_c =$	231.7	50.99	19.78	9.612	5.256	3.077	1.876	1.169	0.734	0.480

When a diaphragm was placed in a tube of uniform section (fig. 90)

FIG. 90.

the following values were obtained, ω_1 being the area of the orifice and ω that of the pipe:—

$\omega_1/\omega =$	0.1	0.2	0.3	0.4	0.5	0.6	0.7	0.8	0.9	1.0
$c_c =$	.624	.632	.643	.659	.681	.712	.755	.813	.892	1.00
$\xi_c =$	225.9	47.77	30.83	7.801	1.753	1.796	.797	.290	.060	.000

Elbows.—Weisbach considers the loss of head at elbows (fig. 91) to be due to a contraction formed by the stream. From experiments with a pipe $1\frac{1}{4}$ in. diameter, he found the loss of head

$$\mathfrak{h}_e = \zeta_e v^2/2g; \qquad (5)$$
$$\zeta_e = 0{\cdot}9457 \sin^2 \tfrac{1}{2}\phi + 2{\cdot}047 \sin^4 \tfrac{1}{2}\phi.$$

$\phi =$	20°	40°	60°	80°	90°	100°	110°	120°	130°	140°
$\zeta_e =$	0.046	0.139	0.364	0.740	0.984	1.260	1.556	1.861	2.158	2.431

Hence at a right-angled elbow the whole head due to the velocity very nearly is lost.

Bends.—Weisbach traces the loss of head at curved bends to a similar cause to that at elbows, but the coefficients for bends are not very satisfactorily ascertained. Weisbach obtained for the loss of head at a bend in a pipe of circular section

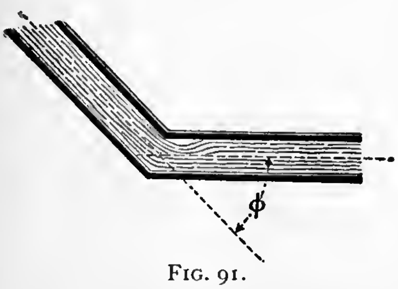

FIG. 91.

$$\mathfrak{h}_b = \zeta_b v^2/2g; \qquad (6)$$
$$\zeta_b = 0{\cdot}131 + 1{\cdot}847 (d/2\rho)^{\frac{7}{2}},$$

where d is the diameter of the pipe and ρ the radius of curvature of the bend. The resistance at bends is small and at present very ill determined.

Valves, Cocks and Sluices.—These produce a contraction of the water-stream, similar to that for an abrupt diminution of section already discussed. The loss of head may be taken as before to be

FIG. 92.

$$\mathfrak{h}_v = \zeta_v v^2/2g; \qquad (7)$$

where v is the velocity in the pipe beyond the valve and ζ_v a coefficient determined by experiment. The following are Weisbach's results.

Sluice in Pipe of Rectangular Section (fig. 92). Section at sluice $= \omega_1$ in pipe $= \omega$.

§ 84. *Practical Calculations on the Flow of Water in Pipes.*—In the following explanations it will be assumed that the pipe is of so great a length that only the loss of head in friction against the surface of the pipe needs to be considered. In general it is one of the four quantities d, i, v or Q which requires to be determined. For since the loss of head h is given by the relation $h = il$, this need not be separately considered.

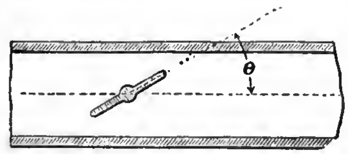

FIG. 95.

There are then three equations (see eq. 4, § 72, and 9a, § 76) for the solution of such problems as arise:—

$$\zeta = \alpha(1 + 1/12d); \qquad (1)$$

where $\alpha = 0{\cdot}005$ for new and $= 0{\cdot}01$ for incrusted pipes.

$$\zeta v^2/2g = \tfrac{1}{4}di. \qquad (2)$$
$$Q = \tfrac{1}{4}\pi d^2 v. \qquad (3)$$

Problem 1. Given the diameter of the pipe and its virtual slope, to find the discharge and velocity of flow. Here d and i are given, and Q and v are required. Find ζ from (1); then v from (2); lastly Q from (3). This case presents no difficulty.

By combining equations (1) and (2), v is obtained directly:—

$$v = \sqrt{(gdi/2\zeta)} = \sqrt{(g/2\alpha)}\sqrt{[di/\{1 + 1/12d\}]}. \qquad (4)$$

For new pipes . . . $\sqrt{(g/2\alpha)} = 56{\cdot}72$
For incrusted pipes . . $= 40{\cdot}13$

For pipes not less than 1, or more than 4 ft. in diameter, the mean values of ζ are

For new pipes . . . . . . 0·00526
For incrusted pipes . . . . . 0·01052.

Using these values we get the very simple expressions—

$$\left.\begin{aligned} v &= 55{\cdot}31\sqrt{(di)} \text{ for new pipes} \\ &= 39{\cdot}11\sqrt{(di)} \text{ for incrusted pipes} \end{aligned}\right\}. \qquad (4a)$$

Within the limits stated, these are accurate enough for practical purposes, especially as the precise value of the coefficient ζ cannot be known for each special case.

Problem 2. Given the diameter of a pipe and the velocity of flow, to find the virtual slope and discharge. The discharge is given by (3); the proper value of ζ by (1); and the virtual slope by (2). This also presents no special difficulty.

Problem 3. Given the diameter of the pipe and the discharge, to find the virtual slope and velocity. Find v from (3); ζ from (1); lastly i from (2). If we combine (1) and (2) we get

$$i = \zeta(v^2/2g)\,(4/d) = 2\alpha\{1 + 1/12d\}v^2/gd; \qquad (5)$$

and, taking the mean values of ζ for pipes from 1 to 4 ft. diameter, given above, the approximate formulae are

$$\left.\begin{aligned} i &= 0{\cdot}0003268\ v^2/d \text{ for new pipes} \\ &= 0{\cdot}0006536\ v^2/d \text{ for incrusted pipes} \end{aligned}\right\}. \qquad (5a)$$

Problem 4. Given the virtual slope and the velocity, to find the diameter of the pipe and the discharge. The diameter is obtained from equations (2) and (1), which give the quadratic expression

$$d^2 - d(2\alpha v^2/gi) - \alpha v^2/6gi = 0.$$
$$\therefore d = \alpha v^2/gi + \sqrt{\{(\alpha v^2/gi)\,(\alpha v^2/gi + 1/6)\}}. \qquad (6)$$

For practical purposes, the approximate equations

$$\begin{aligned} d &= 2\alpha v^2/gi + 1/12 \qquad (6a) \\ &= 0{\cdot}00031\ v^2/i + {\cdot}083 \text{ for new pipes} \\ &= 0{\cdot}00062\ v^2/i + {\cdot}083 \text{ for incrusted pipes} \end{aligned}$$

are sufficiently accurate.

Problem 5. Given the virtual slope and the discharge, to find the diameter of the pipe and velocity of flow. This case, which often occurs in designing, is the one which is least easy of direct solution. From equations (2) and (3) we get—

$$d^5 = 32\zeta Q^2/g\pi^2 i. \qquad (7)$$

If now the value of ζ in (1) is introduced, the equation becomes very cumbrous. Various approximate methods of meeting the difficulty may be used.

(a) Taking the mean values of ζ given above for pipes of 1 to 4 ft. diameter we get

$$\begin{aligned} d &= \sqrt[5]{(32\zeta/g\pi^2)}\sqrt[5]{(Q^2/i)} \qquad (8) \\ &= 0{\cdot}2216\sqrt[5]{(Q^2/i)} \text{ for new pipes} \\ &= 0{\cdot}2541\sqrt[5]{(Q^2/i)} \text{ for incrusted pipes;} \end{aligned}$$

equations which are interesting as showing that when the value of ζ is doubled the diameter of pipe for a given discharge is only increased by 13%.

(*b*) A second method is to obtain a rough value of d by assuming $\zeta = a$. This value is

$$d' = \sqrt[5]{(32Q^2/g\pi^2 i)}\sqrt[5]{a} = 0\cdot6319\sqrt[5]{(Q^2/i)}\sqrt[5]{a}.$$

Then a very approximate value of ζ is

$$\zeta' = a(1+1/12d');$$

and a revised value of d, not sensibly differing from the exact value, is

$$d'' = \sqrt[5]{(32Q^2/g\pi^2 i)}\sqrt[5]{\zeta'} = 0\cdot6319\sqrt[5]{(Q^2/i)}\sqrt[5]{\zeta'}.$$

(*c*) Equation 7 may be put in the form

$$d = \sqrt[5]{(32aQ^2/g\pi^2 i)}\sqrt[5]{(1+1/12d)}. \quad (9)$$

Expanding the term in brackets,

$$\sqrt[5]{(1+1/12d)} = 1+1/60d-1/1800d^2...$$

Neglecting the terms after the second,

$$d = \sqrt[5]{(32a/g\pi^2)}\sqrt[5]{(Q^2/i)}.\{1+1/60d\}$$
$$= \sqrt[5]{(32a/g\pi^2)}\sqrt[5]{(Q^2/i)} + 0\cdot01667; \quad (9a)$$

and

$$\sqrt[5]{(32a/g\pi^2)} = 0\cdot219 \text{ for new pipes}$$
$$= 0\cdot252 \text{ for incrusted pipes.}$$

§ 85. *Arrangement of Water Mains for Towns' Supply.*—Town mains are usually supplied by gravitation from a service reservoir, which in turn is supplied by gravitation from a storage reservoir or by pumping from a lower level. The service reservoir should contain three days' supply or in important cases much more. Its elevation should be such that water is delivered at a pressure of at least about 100 ft. to the highest parts of the district. The greatest pressure in the mains is usually about 200 ft., the pressure for which ordinary pipes and fittings are designed. Hence if the district supplied has

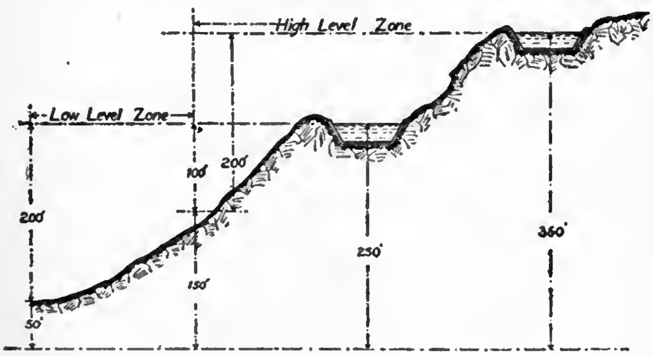

FIG. 96.

great variations of level it must be divided into zones of higher and lower pressure. Fig. 96 shows a district of two zones each with its service reservoir and a range of pressure in the lower district from 100 to 200 ft. The total supply required is in England about 25 gallons per head per day. But in many towns, and especially in America, the supply is considerably greater, but also in many cases

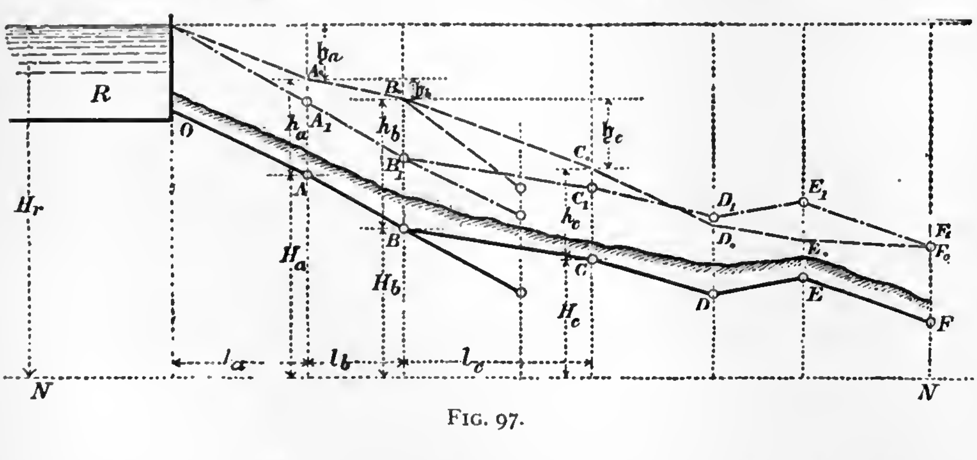

FIG. 97.

a good deal of the supply is lost by leakage of the mains. The supply through the branch mains of a distributing system is calculated from the population supplied. But in determining the capacity of the mains the fluctuation of the demand must be allowed for. It is usual to take the maximum demand at twice the average demand. Hence if the average demand is 25 gallons per head per day, the mains should be calculated for 50 gallons per head per day.

§ 86. *Determination of the Diameters of Different Parts of a Water Main.*—When the plan of the arrangement of mains is determined upon, and the supply to each locality and the pressure required is ascertained, it remains to determine the diameters of the pipes. Let fig. 97 show an elevation of a main ABCD..., R being the reservoir from which the supply is derived. Let NN be the datum line of the levelling operations, and H_a, H_b...the heights of the main above the datum line, H_r being the height of the water surface in the

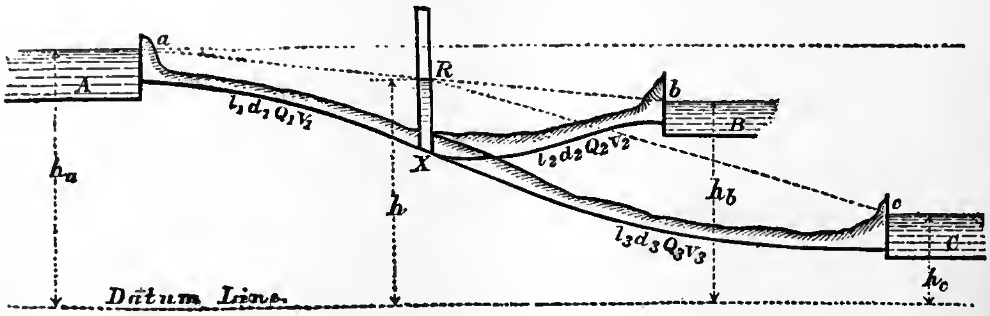

FIG. 98.

reservoir from the same datum. Set up next heights AA_1, BB_1,... representing the minimum pressure height necessary for the adequate supply of each locality. Then $A_1B_1C_1D_1$... is a line which should form a lower limit to the line of virtual slope. Then if heights $\mathfrak{h}_a$, $\mathfrak{h}_b$, $\mathfrak{h}_c$... are taken representing the actual losses of head in each length l_a, l_b, l_c... of the main, $A_0B_0C_0$ will be the line of virtual slope, and it will be obvious at what points such as D_0 and E_0, the pressure is deficient, and a different choice of diameter of main is required. For any point z in the length of the main, we have

$$\text{Pressure height} = H_r - H_z - (\mathfrak{h}_a + \mathfrak{h}_b + \ldots \mathfrak{h}_z).$$

Where no other circumstance limits the loss of head to be assigned to a given length of main, a consideration of the safety of the main from fracture by hydraulic shock leads to a limitation of the velocity of flow. Generally the velocity in water mains lies between 1½ and 4½ ft. per second. Occasionally the velocity in pipes reaches 10 ft. per second, and in hydraulic machinery working under enormous pressures even 20 ft. per second. Usually the velocity diminishes along the main as the discharge diminishes, so as to reduce somewhat the total loss of head which is liable to render the pressure insufficient at the end of the main.

J. T. Fanning gives the following velocities as suitable in pipes for towns' supply:—

Diameter in inches . . .	4	8	12	18	24	30	36
Velocity in feet per sec. . .	2·5	3·0	3·5	4·5	5·3	6·2	7·0

§ 87. *Branched Pipe connecting Reservoirs at Different Levels.*—Let A, B, C (fig. 98) be three reservoirs connected by the arrangement of pipes shown,—l_1, d_1, Q_1, v_1; l_2, d_2, Q_2, v_2; l_3, d_3, Q_3, v_3 being the length, diameter, discharge and velocity in the three portions of the main pipe. Suppose the dimensions and positions of the pipes known and the discharges required.

If a pressure column is introduced at X, the water will rise to a height XR, measuring the pressure at X, and aR, Rb, Rc will be the lines of virtual slope. If the free surface level at R is above b, the reservoir A supplies B and C, and if R is below b, A and B supply C. Consequently there are three cases:—

I. R above b; $Q_1 = Q_2 + Q_3$.
II. R level with b; $Q_1 = Q_3$; $Q_2 = 0$.
III. R below b; $Q_1 + Q_2 = Q_3$.

To determine which case has to be dealt with in the given conditions, suppose the pipe from X to B closed by a sluice. Then there is a simple main, and the height of free surface h' at X can be determined. For this condition

$$h_a - h' = \zeta(v_1^2/2g)(4l_1/d_1) = 32\zeta Q'^2 l_1/g\pi^2 d_1^5;$$
$$h' - h_c = \zeta(v_3^2/2g)(4l_3/d_3) = 32\zeta Q'^2 l_3/g\pi^2 d_3^5;$$

where Q' is the common discharge of the two portions of the pipe. Hence

$$(h_a - h')/(h' - h_c) = l_1 d_3^5/l_3 d_1^5,$$

from which h' is easily obtained. If then h' is greater than hb, opening the sluice between X and B will allow flow towards B, and the case in hand is case I. If h' is less than h_b, opening the sluice will allow flow from B, and the case is case III. If $h' = h_b$, the case is case II., and is already completely solved.

The true value of h must lie between h' and h_b. Choose a new value of h, and recalculate Q_1, Q_2, Q_3. Then if

$$Q_1 > Q_2 + Q_3 \text{ in case I.,}$$

or

$$Q_1 + Q_2 > Q_3 \text{ in case III.,}$$

the value chosen for h is too small, and a new value must be chosen. If

$$Q_1 < Q_2 + Q_3 \text{ in case I.,}$$

or

$$Q_1 + Q_2 < Q_3 \text{ in case III.,}$$

the value of h is too great.

Since the limits between which h can vary are in practical cases not very distant, it is easy to approximate to values sufficiently accurate.

§ 88. *Water Hammer.*—If in a pipe through which water is flowing a sluice is suddenly closed so as to arrest the forward movement of the water, there is a rise of pressure which in some cases is serious enough to burst the pipe. This action is termed water hammer or water ram. The fluctuation of pressure is an oscillating one and gradually dies out. Care is usually taken that sluices should only be closed gradually and then the effect is inappreciable. Very careful experiments on water hammer were made by N. J. Joukowsky at Moscow in 1898 (*Stoss in Wasserleitungen*, St Petersburg, 1900), and the results are generally confirmed by experiments made by E. B. Weston and R. C. Carpenter in America. Joukowsky used pipes, 2, 4 and 6 in. diameter, from 1000 to 2500 ft. in length. The sluice closed in 0·03 second, and the fluctuations of pressure were automatically registered. The maximum excess pressure due to water-hammer action was as follows:—

Pipe 4-in. diameter.		Pipe 6-in. diameter.	
Velocity ft. per sec.	Excess Pressure. ℔ per sq. in.	Velocity ft. per sec.	Excess Pressure. ℔ per sq. in.
0·5	31	0·6	43
2·9	168	3·0	173
4·1	232	5·6	369
9·2	519	7·5	426

In some cases, in fixing the thickness of water mains, 100 ℔ per sq. in. excess pressure is allowed to cover the effect of water hammer. With the velocities usual in water mains, especially as no valves can be quite suddenly closed, this appears to be a reasonable allowance (see also Carpenter, *Am. Soc. Mech. Eng.*, 1893).

IX. FLOW OF COMPRESSIBLE FLUIDS IN PIPES

§ 89. *Flow of Air in Long Pipes.*—When air flows through a long pipe, by far the greater part of the work expended is used in overcoming frictional resistances due to the surface of the pipe. The work expended in friction generates heat, which for the most part must be developed in and given back to the air. Some heat may be transmitted through the sides of the pipe to surrounding materials, but in experiments hitherto made the amount so conducted away appears to be very small, and if no heat is transmitted the air in the tube must remain sensibly at the same temperature during expansion. In other words, the expansion may be regarded as isothermal expansion, the heat generated by friction exactly neutralizing the cooling due to the work done. Experiments on the pneumatic tubes used for the transmission of messages, by R. S. Culley and R. Sabine (*Proc. Inst. Civ. Eng.* xliii.), show that the change of temperature of the air flowing along the tube is much less than it would be in adiabatic expansion.

§ 90. *Differential Equation of the Steady Motion of Air Flowing in a Long Pipe of Uniform Section.*—When air expands at a constant absolute temperature τ, the relation between the pressure p in pounds per square foot and the density or weight per cubic foot G is given by the equation

$$p/G = c\tau, \tag{1}$$

where $c = 53·15$. Taking $\tau = 521$, corresponding to a temperature of 60° Fahr.,

$$c\tau = 27690 \text{ foot-pounds.} \tag{2}$$

The equation of continuity, which expresses the condition that in steady motion the same weight of fluid, W, must pass through each cross section of the stream in the unit of time, is

$$G\Omega u = W = \text{constant}, \tag{3}$$

where Ω is the section of the pipe and u the velocity of the air. Combining (1) and (3),

$$\Omega up/W = c\tau = \text{constant}. \tag{3a}$$

Since the work done by gravity on the air during its flow through a pipe due to variations of its level is generally small compared with the work done by changes of pressure, the former may in many cases be neglected.

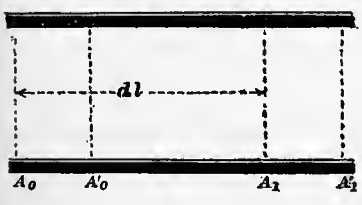

FIG. 99.

Consider a short length dl of the pipe limited by sections A_0, A_1 at a distance dl (fig. 99). Let p, u be the pressure and velocity at A_0, $p+dp$ and $u+du$ those at A_1. Further, suppose that in a very short time dt the mass of air between A_0A_1 comes to $A'_0A'_1$ so that $A_0A'_0 = udt$ and $A_1A'_1 = (u+du)dt_1$. Let Ω be the section, and m the hydraulic mean radius of the pipe, and W the weight of air flowing through the pipe per second.

From the steadiness of the motion the weight of air between the sections $A_0A'_0$, and $A_1A'_1$ is the same. That is,

$$Wdt = G\Omega udt = G\Omega(u+du)dt.$$

By analogy with liquids the head lost in friction is, for the length dl (see § 72, eq. 3), $\zeta(u^2/2g)(dl/m)$. Let $H = u^2/2g$. Then the head lost is $\zeta(H/m)dl$; and, since Wdt ℔ of air flow through the pipe in the time considered, the work expended in friction is $-\zeta(H/m)Wdl\,dt$. The change of kinetic energy in dt seconds is the difference of the kinetic energy of $A_0A'_0$ and $A_1A'_1$, that is,

$$(W/g)dt\{(u+du)^2 - u^2\}/2 = (W/g)\,u\,du\,dt = WdHdt.$$

The work of expansion when Ωudt cub. ft. of air at a pressure p expand to $\Omega(u+du)dt$ cub. ft. is $\Omega p\,du\,dt$. But from (3a) $u = c\tau W/\Omega p$, and therefore

$$du/dp = -c\tau W/\Omega p^2.$$

And the work done by expansion is $-(c\tau W/p)dp\,dt$.

The work done by gravity on the mass between A_0 and A_1 is zero if the pipe is horizontal, and may in other cases be neglected without great error. The work of the pressures at the sections A_0A_1 is

$$p\Omega udt - (p+dp)\Omega(u+du)dt$$
$$= -(pdu + udp)\Omega dt.$$

But from (3a)

$$pu = \text{constant},$$
$$pdu + udp = 0,$$

and the work of the pressures is zero. Adding together the quantities of work, and equating them to the change of kinetic energy,

$$WdHdt = -(c\tau W/p)dp\,dt - \zeta(H/m)W\,dl\,dt$$
$$dH + (c\tau/p)dp + \zeta(H/m)dl = 0,$$
$$dH/H + (c\tau/Hp)dp + \zeta dl/m = 0, \tag{4}$$

But

$$u = c\tau W/\Omega p,$$

and

$$H = u^2/2g = c^2\tau^2W^2/2g\Omega^2p^2,$$
$$\therefore dH/H + (2g\Omega^2p/c\tau W^2)dp + \zeta dl/m = 0. \tag{4a}$$

For tubes of uniform section m is constant; for steady motion W is constant; and for isothermal expansion τ is constant. Integrating,

$$\log H + g\Omega^2p^2/W^2c\tau + \zeta l/m = \text{constant}; \tag{5}$$

for $l = 0$, let $H = H_0$, and $p = p_0$;

and for $l = l$, let $H = H_1$, and $p = p_1$.

$$\log(H_1/H_0) + (g\Omega^2/W^2c\tau)(p_1^2 - p_0^2) + \zeta l/m = 0. \tag{5a}$$

where p_0 is the greater pressure and p_1 the less, and the flow is from A_0 towards A_1.

By replacing W and H,

$$\log(p_0/p_1) + (gc\tau/u_0^2p_0^2)(p_1^2 - p_0^2) + \zeta l/m = 0. \tag{6}$$

Hence the initial velocity in the pipe is

$$u_0 = \sqrt{[\{gc\tau(p_0^2 - p_1^2)\}/\{p_0^2(\zeta l/m + \log(p_0/p_1)\}]}. \tag{7}$$

When l is great, $\log p_0/p_1$ is comparatively small, and then

$$u_0 = \sqrt{[(gc\tau m/\zeta l)\{(p_0^2 - p_1^2)/p_0^2\}]}, \tag{7a}$$

a very simple and easily used expression. For pipes of circular section $m = d/4$, where d is the diameter:—

$$u_0 = \sqrt{[(gc\tau d/4\zeta l)\{(p_0^2 - p_1^2)/p_0^2\}]}; \tag{7b}$$

or approximately

$$u_0 = (1·1319 - 0·7264p_1/p_0)\sqrt{(gc\tau d/4\zeta l)}. \tag{7c}$$

§ 91. *Coefficient of Friction for Air.*—A discussion by Professor Unwin of the experiments by Culley and Sabine on the rate of transmission of light carriers through pneumatic tubes, in which there is steady flow of air not sensibly affected by any resistances other than surface friction, furnished the value $\zeta = ·007$. The pipes were lead pipes, slightly moist, $2\frac{1}{4}$ in. (0·187 ft.) in diameter, and in lengths of 2000 to nearly 6000 ft.

In some experiments on the flow of air through cast-iron pipes A. Arson found the coefficient of friction to vary with the velocity and diameter of the pipe. Putting

$$\zeta = a/v + \beta, \tag{8}$$

he obtained the following values—

Diameter of Pipe in feet.	a	β	ζ for 100 ft. per second.
1·64	·00129	·00483	·00484
1·07	·00972	·00640	·00650
·83	·01525	·00704	·00719
·338	·03604	·00941	·00977
·266	·03790	·00959	·00997
·164	·04518	·01167	·01212

It is worth while to try if these numbers can be expressed in the form proposed by Darcy for water. For a velocity of 100 ft. per second, and without much error for higher velocities, these numbers agree fairly with the formula

$$\zeta = 0·005(1 + 3/10d), \tag{9}$$

which only differs from Darcy's value for water in that the second term, which is always small except for very small pipes, is larger.

Some later experiments on a very large scale, by E. Stockalper at the St Gotthard Tunnel, agree better with the value

$$\zeta = 0{\cdot}0028(1 + 3/10d).$$

These pipes were probably less rough than Arson's.

When the variation of pressure is very small, it is no longer safe to neglect the variation of level of the pipe. For that case we may neglect the work done by expansion, and then

$$z_0 - z_1 - p_0/G_0 - p_1/G_1 - \zeta(v^2/2g)\ (l/m) = 0, \qquad (10)$$

precisely equivalent to the equation for the flow of water, z_0 and z_1 being the elevations of the two ends of the pipe above any datum, p_0 and p_1 the pressures, G_0 and G_1 the densities, and v the mean velocity in the pipe. This equation may be used for the flow of coal gas.

§ 92. *Distribution of Pressure in a Pipe in which Air is Flowing.*—From equation (7a) it results that the pressure p, at l ft. from that end of the pipe where the pressure is p_0, is

$$p = p_0\sqrt{\{1 - \zeta l u_0^2/mgc\tau\}}; \qquad (11)$$

which is of the form

$$p = \sqrt{(al + b)}$$

for any given pipe with given end pressures. The curve of free surface level for the pipe is, therefore, a parabola with horizontal axis. Fig. 100 shows calculated curves of pressure for two of Sabine's experiments, in one of which the pressure was greater than atmospheric pressure, and in the other less than atmospheric pressure. The observed pressures are given in brackets and the calculated pressures without brackets. The pipe was the pneumatic tube between Fenchurch Street and the Central Station, 2818 yds. in length. The pressures are given in inches of mercury.

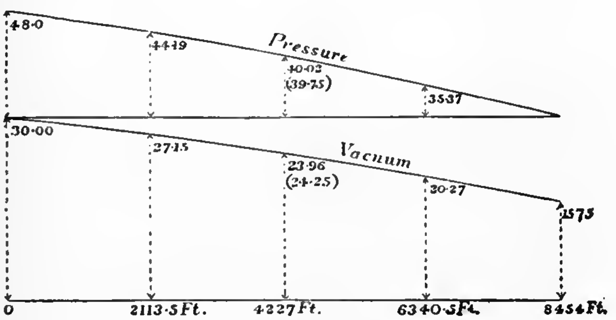

FIG. 100.

Variation of Velocity in the Pipe.—Let p_0, u_0 be the pressure and velocity at a given section of the pipe; p, u, the pressure and velocity at any other section. From equation (3a)

$$up = c\tau W/\Omega = \text{constant};$$

so that, for any given uniform pipe,

$$up = u_0 p_0,$$
$$u = u_0 p_0/p; \qquad (12)$$

which gives the velocity at any section in terms of the pressure, which has already been determined. Fig. 101 gives the velocity curves for the two experiments of Culley and Sabine, for which the pressure curves have already been drawn. It will be seen that the velocity increases considerably towards that end of the pipe where the pressure is least.

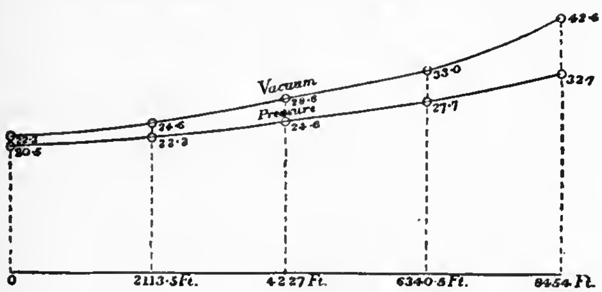

FIG. 101.

§ 93. *Weight of Air Flowing per Second.*—The weight of air discharged per second is (equation 3a)—

$$W = \Omega u_0 p_0/c\tau.$$

From equation (7b), for a pipe of circular section and diameter d,

$$W = \tfrac{1}{4}\pi\sqrt{\{gd^5(p_0^2 - p_1^2)/\zeta l c\tau\}},$$
$$= {\cdot}611\sqrt{\{d^5(p_0^2 - p_1^2)/\zeta l\tau\}}. \qquad (13)$$

Approximately

$$W = ({\cdot}6916p_0 - {\cdot}4438p_1)\ (d^5/\zeta l\tau)^{\frac{1}{2}}. \qquad (13a)$$

§ 94. *Application to the Case of Pneumatic Tubes for the Transmission of Messages.*—In Paris, Berlin, London, and other towns, it has been found cheaper to transmit messages in pneumatic tubes than to telegraph by electricity. The tubes are laid underground with easy curves; the messages are made into a roll and placed in a light felt carrier, the resistance of which in the tubes in London is only $\frac{3}{4}$ oz. A current of air forced into the tube or drawn through it propels the carrier. In most systems the current of air is steady and continuous, and the carriers are introduced or removed without materially altering the flow of air.

Time of Transit through the Tube.—Putting t for the time of transit from 0 to l,

$$t = \int_0^l dl/u,$$

From (4a) neglecting dH/H, and putting $m = d/4$,

$$dl = gd\Omega^2 p\,dp/2\zeta W^2 cr.$$

From (1) and (3)

$$u = Wc\tau/p\Omega;$$
$$dl/u = gd\Omega^3 p^2 dp/2\zeta W^3 c^2\tau^2;$$
$$t = \int_{p_1}^{p_0} gd\Omega^3 p^2 dp/2\zeta W^3 c^2\tau^2,$$
$$= gd\Omega^3(p_0^3 - p_1^3)/6\zeta W^3 c^2\tau^2. \qquad (14)$$

But

$$W = p_0 u_0 \Omega/c\tau;$$
$$\therefore t = gdc\tau(p_0^3 - p_1^3)/6\zeta p_0^3 u_0^3,$$
$$= \zeta^{\frac{1}{2}} l^{\frac{3}{2}}(p_0^3 - p_1^3)/6(gc\tau d)^{\frac{1}{2}}(p_0^2 - p_1^3)^{\frac{3}{2}}. \qquad (15)$$

If $\tau = 521°$, corresponding to 60° F.,

$$t = {\cdot}001412\zeta^{\frac{1}{2}} l^{\frac{3}{2}}(p_0^3 - p_1^3)/d^{\frac{1}{2}}(p_0^2 - p_1^2)^{\frac{3}{2}}; \qquad (15a)$$

which gives the time of transmission in terms of the initial and final pressures and the dimensions of the tube.

Mean Velocity of Transmission.—The mean velocity is l/t; or, for $\tau = 521°$,

$$u_{\text{mean}} = 0{\cdot}708\sqrt{\{d(p_0^2 - p_1^2)^{\frac{3}{2}}/\zeta l(p_0^3 - p_1^3)\}}. \qquad (16)$$

The following table gives some results:—

	Absolute Pressures in lb per sq. in.		Mean Velocities for Tubes of a length in feet.				
	p_0	p_1	1000	2000	3000	4000	5000
Vacuum Working	15	5	99·4	70·3	57·4	49·7	44·5
	15	10	67·2	47·5	38·8	34·4	30·1
Pressure Working	20	15	57·2	40·5	33·0	28·6	25·6
	25	15	74·6	52·7	43·1	37·3	33·3
	30	15	84·7	60·0	49·0	42·4	37·9

Limiting Velocity in the Pipe when the Pressure at one End is diminished indefinitely.—If in the last equation there be put $p_1 = 0$, then

$$u'_{\text{mean}} = 0{\cdot}708\sqrt{(d/\zeta l)};$$

where the velocity is independent of the pressure p_0 at the other end, a result which apparently must be absurd. Probably for long pipes, as for orifices, there is a limit to the ratio of the initial and terminal pressures for which the formula is applicable.

X. FLOW IN RIVERS AND CANALS

§ 95. *Flow of Water in Open Canals and Rivers.*—When water flows in a pipe the section at any point is determined by the form of the boundary. When it flows in an open channel with free upper surface, the section depends on the velocity due to the dynamical conditions.

Suppose water admitted to an unfilled canal. The channel will gradually fill, the section and velocity at each point gradually changing. But if the inflow to the canal at its head is constant, the increase of cross section and diminution of velocity at each point attain after a time a limit. Thenceforward the section and velocity at each point are constant, and the motion is steady, or permanent regime is established.

If when the motion is steady the sections of the stream are all equal, the motion is uniform. By hypothesis, the inflow Ωv is constant for all sections, and Ω is constant; therefore v must be constant also from section to section. The case is then one of uniform steady motion. In most artificial channels the form of section is constant, and the bed has a uniform slope. In that case the motion is uniform, the depth is constant, and the stream surface is parallel to the bed. If when steady motion is established the sections are unequal, the motion is steady motion with varying velocity from section to section. Ordinary rivers are in this condition, especially where the flow is modified by weirs or obstructions. Short unobstructed lengths of a river may be treated as of uniform section without great error, the mean section in the length being put for the actual sections.

In all actual streams the different fluid filaments have different velocities, those near the surface and centre moving faster than those near the bottom and sides. The ordinary formulae for the flow of streams rest on a hypothesis that this variation of velocity may be neglected, and that all the filaments may be treated as having a common velocity equal to the mean velocity of the stream. On this hypothesis, a plane layer *abab* (fig. 102) between sections normal to the direction of motion is treated as sliding down the channel to $a'a'b'b'$ without deformation. The component of the weight parallel to the channel bed balances the friction against the channel, and in estimating the friction the velocity of rubbing is taken to be the mean velocity of the stream. In actual streams, however, the velocity of rubbing on which the friction depends is not the mean velocity of the stream, and is not in any simple relation with it, for channels of different forms. The theory is therefore obviously based on an imperfect hypothesis. However, by taking variable values for the coefficient of friction, the errors of the ordinary formulae are to a great extent neutralized, and they may be used without leading to practical errors. Formulae have been obtained based on less restricted hypotheses, but at present they are not practically so reliable, and are more complicated than the formulae obtained in the manner described above.

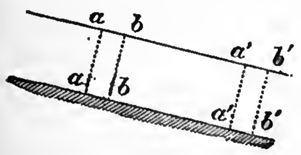

FIG. 102.

§ 96. *Steady Flow of Water with Uniform Velocity in Channels of Constant Section.*—Let aa', bb' (fig. 103) be two cross sections normal to the direction of motion at a distance dl. Since the mass $aa'bb'$ moves uniformly, the external forces acting on it are in equilibrium. Let Ω be the area of the cross sections, χ the wetted perimeter,

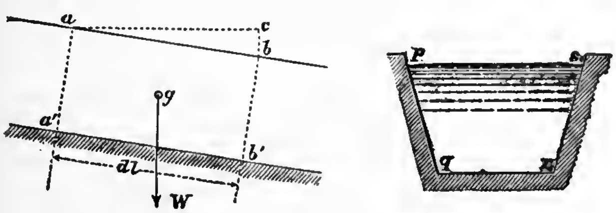

FIG. 103.

$pq+qr+rs$, of a section. Then the quantity $m=\Omega/\chi$ is termed the hydraulic mean depth of the section. Let v be the mean velocity of the stream, which is taken as the common velocity of all the particles, i, the slope or fall of the stream in feet, per foot, being the ratio bc/ab.

The external forces acting on $aa'bb'$ parallel to the direction of motion are three:—(*a*) The pressures on aa' and bb', which are equal and opposite since the sections are equal and similar, and the mean pressures on each are the same. (*b*) The component of the weight W of the mass in the direction of motion, acting at its centre of gravity g. The weight of the mass $aa'bb'$ is $G\Omega dl$, and the component of the weight in the direction of motion is $G\Omega dl \times$ the cosine of the angle between Wg and ab, that is, $G\Omega dl \cos abc = G\Omega dl\, bc/ab = G\Omega i dl$. (*c*) There is the friction of the stream on the sides and bottom of the channel. This is proportional to the area χdl of rubbing surface and to a function of the velocity which may be written $f(v)$; $f(v)$ being the friction per sq. ft. at a velocity v. Hence the friction is $-\chi dl\, f(v)$. Equating the sum of the forces to zero,

$$G\Omega i\, dl - \chi dl\, f(v) = 0,$$
$$f(v)/G = \Omega i/\chi = mi. \qquad (1)$$

But it has been already shown (§ 66) that $f(v) = \zeta G v^2/2g$,

$$\therefore \zeta v^2/2g = mi. \qquad (2)$$

This may be put in the form

$$v = \sqrt{(2g/\zeta)}\sqrt{(mi)} = c\sqrt{(mi)}; \qquad (2a)$$

where c is a coefficient depending on the roughness and form of the channel.

The coefficient of friction ζ varies greatly with the degree of roughness of the channel sides, and somewhat also with the velocity. It must also be made to depend on the absolute dimensions of the section, to eliminate the error of neglecting the variations of velocity in the cross section. A common mean value assumed for ζ is 0·00757. The range of values will be discussed presently.

It is often convenient to estimate the fall of the stream in feet per mile, instead of in feet per foot. If f is the fall in feet per mile,

$$f = 5280\, i.$$

Putting this and the above value of ζ in (2*a*), we get the very simple and long-known approximate formula for the mean velocity of a stream—

$$v = \tfrac{11}{12}\sqrt{(2mf)}. \qquad (3)$$

The flow down the stream per second, or discharge of the stream, is

$$Q = \Omega v = \Omega v\sqrt{(mi)}. \qquad (4)$$

§ 97. *Coefficient of Friction for Open Channels.*—Various expressions have been proposed for the coefficient of friction for channels as for pipes. Weisbach, giving attention chiefly to the variation of the coefficient of friction with the velocity, proposed an expression of the form

$$\zeta = \alpha(1+\beta/v), \qquad (5)$$

and from 255 experiments obtained for the constants the values

$$\alpha = 0{\cdot}007409;\ \beta = 0{\cdot}1920.$$

This gives the following values at different velocities:—

$v=$	0·3	0·5	0·7	1	$1\frac{1}{2}$	2	3	5	7	10	15
$\zeta=$	0·01215	0·01025	0·00944	0·00883	0·00836	0·00812	0·90788	0·00769	0·00761	0·00755	0·00750

In using this value of ζ when v is not known, it is best to proceed by approximation.

§ 98. *Darcy and Bazin's Expression for the Coefficient of Friction.*—Darcy and Bazin's researches have shown that ζ varies very greatly for different degrees of roughness of the channel bed, and that it also varies with the dimensions of the channel. They give for ζ an empirical expression (similar to that for pipes) of the form

$$\zeta = \alpha(1+\beta/m); \qquad (6)$$

where m is the hydraulic mean depth. For different kinds of channels they give the following values of the coefficient of friction:—

Kind of Channel.	α	β
I. Very smooth channels, sides of smooth cement or planed timber	0·00294	0·10
II. Smooth channels, sides of ashlar, brickwork, planks	0·00373	0·23
III. Rough channels, sides of rubble masonry or pitched with stone	0·00471	0·82
IV. Very rough canals in earth	0·00549	4·10
V. Torrential streams encumbered with detritus	0·00785	5·74

The last values (Class V.) are not Darcy and Bazin's, but are taken from experiments by Ganguillet and Kutter on Swiss streams.

The following table very much facilitates the calculation of the mean velocity and discharge of channels, when Darcy and Bazin's value of the coefficient of friction is used. Taking the general formula for the mean velocity already given in equation (2*a*) above,

$$v = c\sqrt{(mi)},$$

where $c = \sqrt{(2g/\zeta)}$, the following table gives values of c for channels of different degrees of roughness, and for such values of the hydraulic mean depths as are likely to occur in practical calculations:—

Values of c *in* v = c√ (mi), *deduced from Darcy and Bazin's Values.*

Hydraulic Mean Depth = *m*.	Very Smooth Channels. Cement.	Smooth Channels. Ashlar or Brickwork.	Rough Channels. Rubble Masonry.	Very Rough Channels. Canals in Earth.	Excessively Rough Channels encumbered with Detritus.	Hydraulic Mean Depth = *m*.	Very Smooth Channels. Cement.	Smooth Channels. Ashlar or Brickwork.	Rough Channels. Rubble Masonry.	Very Rough Channels. Canals in Earth.	Excessively Rough Channels encumbered with Detritus.

§ 99. *Ganguillet and Kutter's Modified Darcy Formula.*—Starting from the general expression $v = c\sqrt{mi}$, Ganguillet and Kutter examined the variations of c for a wider variety of cases than those discussed by Darcy and Bazin. Darcy and Bazin's experiments were confined to channels of moderate section, and to a limited variation of slope. Ganguillet and Kutter brought into the discussion two very distinct and important additional series of results. The gaugings of the Mississippi by A. A. Humphreys and L. H. Abbot afford data of discharge for the case of a stream of exceptionally large section and of very low slope. On the other hand, their own measurements of the flow in the regulated channels of some

Swiss torrents gave data for cases in which the inclination and roughness of the channels were exceptionally great. Darcy and Bazin's experiments alone were conclusive as to the dependence of the coefficient c on the dimensions of the channel and on its roughness of surface. Plotting values of c for channels of different inclination appeared to indicate that it also depended on the slope of the stream. Taking the Mississippi data only, they found

$$c = 256 \text{ for an inclination of } 0\cdot0034 \text{ per thousand,}$$
$$= 154 \quad \text{,,} \quad \text{,,} \quad 0\cdot02 \quad \text{,,}$$

so that for very low inclinations no constant value of c independent of the slope would furnish good values of the discharge. In small rivers, on the other hand, the values of c vary little with the slope. As regards the influence of roughness of the sides of the channel a different law holds. For very small channels differences of roughness have a great influence on the discharge, but for very large channels different degrees of roughness have but little influence, and for indefinitely large channels the influence of different degrees of roughness must be assumed to vanish. The coefficients given by Darcy and Bazin are different for each of the classes of channels of different roughness, even when the dimensions of the channel are infinite. But, as it is much more probable that the influence of the nature of the sides diminishes indefinitely as the channel is larger, this must be regarded as a defect in their formula.

Comparing their own measurements in torrential streams in Switzerland with those of Darcy and Bazin, Ganguillet and Kutter found that the four classes of coefficients proposed by Darcy and Bazin were insufficient to cover all cases. Some of the Swiss streams gave results which showed that the roughness of the bed was markedly greater than in any of the channels tried by the French engineers. It was necessary therefore in adopting the plan of arranging the different channels in classes of approximately similar roughness to increase the number of classes. Especially an additional class was required for channels obstructed by detritus.

To obtain a new expression for the coefficient in the formula

$$v = \sqrt{(2g/\zeta)}\sqrt{(mi)} = c\sqrt{(mi)},$$

Ganguillet and Kutter proceeded in a purely empirical way. They found that an expression of the form

$$c = \alpha/(1+\beta/\sqrt{m})$$

could be made to fit the experiments somewhat better than Darcy's expression. Inverting this, we get

$$1/c = 1/\alpha + \beta/\alpha\sqrt{m},$$

an equation to a straight line having $1/\sqrt{m}$ for abscissa, $1/c$ for ordinate, and inclined to the axis of abscissae at an angle the tangent of which is β/α.

Plotting the experimental values of $1/c$ and $1/\sqrt{m}$, the points so found indicated a curved rather than a straight line, so that β must depend on α. After much comparison the following form was arrived at—

$$c = (\text{A}+l/n)/(1+\text{A}n/\sqrt{m}),$$

where n is a coefficient depending only on the roughness of the sides of the channel, and A and l are new coefficients, the value of which remains to be determined. From what has been already stated, the coefficient c depends on the inclination of the stream, decreasing as the slope i increases.

Let $$\text{A} = a + p/i.$$

Then $$c = (a + l/n + p/i)/\{1 + (a+p/i)n/\sqrt{m}\},$$

the form of the expression for c ultimately adopted by Ganguillet and Kutter.

For the constants a, l, p Ganguillet and Kutter obtain the values 23, 1 and 0·00155 for metrical measures, or 41·6, 1·811 and 0·00281 for English feet. The coefficient of roughness n is found to vary from 0·008 to 0·050 for either metrical or English measures.

The most practically useful values of the coefficient of roughness n are given in the following table:—

Nature of Sides of Channel.	Coefficient of Roughness n.
Well-planed timber	0·009
Cement plaster	0·010
Plaster of cement with one-third sand	0·011
Unplaned planks	0·012
Ashlar and brickwork	0·013
Canvas on frames	0·015
Rubble masonry	0·017
Canals in very firm gravel	0·020
Rivers and canals in perfect order, free from stones or weeds	0·025
Rivers and canals in moderately good order, not quite free from stones and weeds	0·030
Rivers and canals in bad order, with weeds and detritus	0·035
Torrential streams encumbered with detritus	0·050

Ganguillet and Kutter's formula is so cumbrous that it is difficult to use without the aid of tables.

Lowis D'A. Jackson published complete and extensive tables for facilitating the use of the Ganguillet and Kutter formula (*Canal and Culvert Tables*, London, 1878). To lessen calculation he puts the formula in this form:—

$$\text{M} = n(41\cdot6 + 0\cdot00281/i);$$
$$v = (\sqrt{m}/n)\{(\text{M}+1\cdot811)/(\text{M}+\sqrt{m})\}\sqrt{(mi)}.$$

The following table gives a selection of values of M, taken from Jackson's tables:—

$i=$	Values of M for $n=$						
	0·010	0·012	0·015	0·017	0·020	0·025	0·030
·00001	3·2260	3·8712	4·8390	5·4842	6·4520	8·0650	9·6780
·00002	1·8210	2·1852	2·7315	3·0957	3·6420	4·5525	5·4630
·00004	1·1185	1·3422	1·6777	1·9014	2·2370	2·7962	3·3555
·00006	0·8843	1·0612	1·3264	1·5033	1·7686	2·2107	2·6529
·00008	0·7672	0·9206	1·1508	1·3042	1·5344	1·9180	2·3016
·00010	0·6970	0·8364	1·0455	1·1849	1·3940	1·7425	2·0910
·00025	0·5284	0·6341	0·7926	0·8983	1·0568	1·3210	1·5852
·00050	0·4722	0·5666	0·7083	0·8027	0·9444	1·1805	1·4166
·00075	0·4535	0·5442	0·6802	0·7709	0·9070	1·1337	1·3605
·00100	0·4441	0·5329	0·6661	0·7550	0·8882	1·1102	1·3323
·00200	0·4300	0·5160	0·6450	0·7310	0·8600	1·0750	1·2900
·00300	0·4254	0·5105	0·6381	0·7232	0·8508	1·0635	1·2762

A difficulty in the use of this formula is the selection of the coefficient of roughness. The difficulty is one which no theory will overcome, because no absolute measure of the roughness of stream beds is possible. For channels lined with timber or masonry the difficulty is not so great. The constants in that case are few and sufficiently defined. But in the case of ordinary canals and rivers the case is different, the coefficients having a much greater range. For artificial canals in rammed earth or gravel n varies from 0·0163 to 0·0301. For natural channels or rivers n varies from 0·020 to 0·035.

In Jackson's opinion even Kutter's numerous classes of channels seem inadequately graduated, and he proposes for artificial canals the following classification:—

I.	Canals in very firm gravel, in perfect order	$n = 0\cdot02$
II.	Canals in earth, above the average in order	$n = 0\cdot0225$
III.	Canals in earth, in fair order	$n = 0\cdot025$
IV.	Canals in earth, below the average in order	$n = 0\cdot0275$
V.	Canals in earth, in rather bad order, partially overgrown with weeds and obstructed by detritus	$n = 0\cdot03$

Ganguillet and Kutter's formula has been considerably used partly from its adoption in calculating tables for irrigation work in India. But it is an empirical formula of an unsatisfactory form. Some engineers apparently have assumed that because it is complicated it must be more accurate than simpler formulae. Comparison with the results of gaugings shows that this is not the case. The term involving the slope was introduced to secure agreement with some early experiments on the Mississippi, and there is strong reason for doubting the accuracy of these results.

§ 100. *Bazin's New Formula.*—Bazin subsequently re-examined all the trustworthy gaugings of flow in channels and proposed a modification of the original Darcy formula which appears to be more satisfactory than any hitherto suggested (*Étude d'une nouvelle formule*, Paris, 1898). He points out that Darcy's original formula, which is of the form $mi/v^2 = \alpha + \beta/m$, does not agree with experiments on channels as well as with experiments on pipes. It is an objection to it that if m increases indefinitely the limit towards which mi/v^2 tends is different for different values of the roughness. It would seem that if the dimensions of a canal are indefinitely increased the variation of resistance due to differing roughness should vanish. This objection is met if it is assumed that $\sqrt{(mi/v^2)} = a + \beta/\sqrt{m}$, so that if a is a constant mi/v^2 tends to the limit a when m increases. A very careful discussion of the results of gaugings shows that they can be expressed more satisfactorily by this new formula than by Ganguillet and Kutter's. Putting the equation in the form $\zeta v^2/2g = mi$, $\zeta = 0\cdot002594(1+\gamma/\sqrt{m})$, where γ has the following values:—

I.	Very smooth sides, cement, planed plank, $\gamma =$	0·109
II.	Smooth sides, planks, brickwork	0·290
III.	Rubble masonry sides	0·833
IV.	Sides of very smooth earth, or pitching	1·539
V.	Canals in earth in ordinary condition	2·353
VI.	Canals in earth exceptionally rough	3·168

§ 101. *The Vertical Velocity Curve.*—If at each point along a vertical representing the depth of a stream, the velocity at that point is plotted horizontally, the curve obtained is the vertical velocity curve and it has been shown by many observations that it approximates to a parabola with horizontal axis. The vertex of the parabola is at the level of the greatest velocity. Thus in fig. 104 OA is the vertical at which velocities are observed; v_o is the surface; v_z the maximum and v_d the bottom velocity. B C D is the vertical velocity curve which corresponds with a parabola having its vertex at C. The mean velocity at the vertical is

$$v_m = \tfrac{1}{3}[2v_z + v_d + (d_z/d)(v_o - v_d)].$$

The Horizontal Velocity Curve.—Similarly if at each point along a horizontal representing the width of the stream the velocities are plotted, a curve is obtained called the horizontal velocity curve. In streams of symmetrical section this is a curve symmetrical about the centre line of the stream. The velocity varies little near the centre of the stream, but very rapidly near the banks. In unsymmetrical sections the greatest velocity is at the point where the stream is deepest, and the general form of the horizontal velocity curve is roughly similar to the section of the stream.

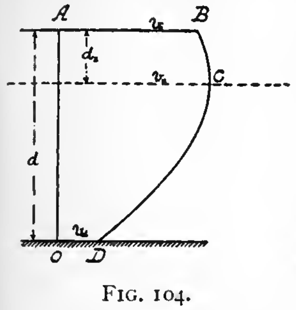

FIG. 104.

§ 102. *Curves or Contours of Equal Velocity.*—If velocities are observed at a number of points at different widths and depths in a stream, it is possible to draw curves on the cross section through points at which the velocity is the same. These represent contours of a solid, the volume of which is the discharge of the stream per second. Fig. 105 shows the vertical and horizontal velocity curves and the contours of equal velocity in a rectangular channel, from one of Bazin's gaugings.

§ 103. *Experimental Observations on the Vertical Velocity Curve.*—A preliminary difficulty arises in observing the velocity at a given point in a stream because the velocity rapidly varies, the motion not being strictly steady. If an average of several velocities at the same point is taken, or the average velocity for a sensible period of time, this average is found to be constant. It may be inferred that

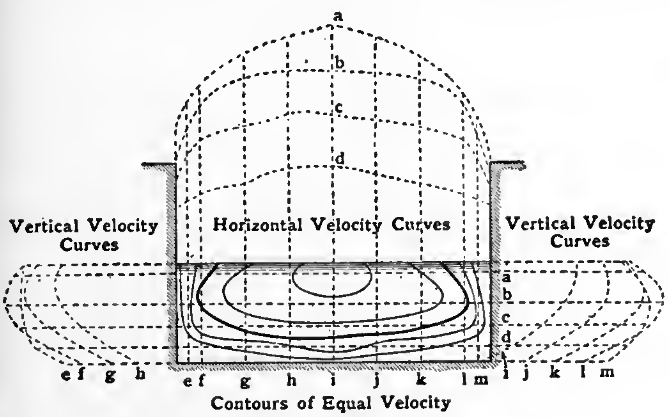

FIG. 105.

though the velocity at a point fluctuates about a mean value, the fluctuations being due to eddying motions superposed on the general motion of the stream, yet these fluctuations produce effects which disappear in the mean of a series of observations and, in calculating the volume of flow, may be disregarded.

In the next place it is found that in most of the best observations on the velocity in streams, the greatest velocity at any vertical is found not at the surface but at some distance below it. In various river gaugings the depth d_z at the centre of the stream has been found to vary from 0 to $0{\cdot}3d$.

§ 104. *Influence of the Wind.*—In the experiments on the Mississippi the vertical velocity curve in calm weather was found to agree fairly with a parabola, the greatest velocity being at $\frac{3}{10}$ths of the depth of the stream from the surface. With a wind blowing down stream the surface velocity is increased, and the axis of the parabola approaches the surface. On the contrary, with a wind blowing up stream the surface velocity is diminished, and the axis of the parabola is lowered, sometimes to half the depth of the stream. The American observers drew from their observations the conclusion that there was an energetic retarding action at the surface of a stream like that due to the bottom and sides. If there were such a retarding action the position of the filament of maximum velocity below the surface would be explained.

It is not difficult to understand that a wind acting on surface ripples or waves should accelerate or retard the surface motion of the stream, and the Mississippi results may be accepted so far as showing that the surface velocity of a stream is variable when the mean velocity of the stream is constant. Hence observations of surface velocity by floats or otherwise should only be made in very calm weather. But it is very difficult to suppose that, in still air, there is a resistance at the free surface of the stream at all analogous to that at the sides and bottom. Further, in very careful experiments, P. P. Boileau found the maximum velocity, though raised a little above its position for calm weather, still at a considerable distance below the surface, even when the wind was blowing down stream with a velocity greater than that of the stream, and when the action of the air must have been an accelerating and not a retarding action. A much more probable explanation of the diminution of the velocity at and near the free surface is that portions of water, with a diminished velocity from retardation by the sides or bottom, are thrown off in eddying masses and mingle with the rest of the stream. These eddying masses modify the velocity in all parts of the stream, but have their greatest influence at the free surface. Reaching the free surface they spread out and remain there, mingling with the water at that level and diminishing the velocity which would otherwise be found there.

Influence of the Wind on the Depth at which the Maximum Velocity is found.—In the gaugings of the Mississippi the vertical velocity curve was found to agree well with a parabola having a horizontal axis at some distance below the water surface, the ordinate of the parabola at the axis being the maximum velocity of the section. During the gaugings the force of the wind was registered on a scale ranging from 0 for a calm to 10 for a hurricane. Arranging the velocity curves in three sets—(1) with the wind blowing up stream, (2) with the wind blowing down stream, (3) calm or wind blowing across stream—it was found that an up-stream wind lowered, and a down-stream wind raised, the axis of the parabolic velocity curve. In calm weather the axis was at $\frac{3}{10}$ths of the total depth from the surface for all conditions of the stream.

Let h' be the depth of the axis of the parabola, m the hydraulic mean depth, f the number expressing the force of the wind, which may range from $+10$ to -10, positive if the wind is up stream, negative if it is down stream. Then Humphreys and Abbot find their results agree with the expression

$$h'/m = 0{\cdot}317 \pm 0{\cdot}06f.$$

Fig. 106 shows the parabolic velocity curves according to the American observers for calm weather, and for an up- or down-stream wind of a force represented by 4.

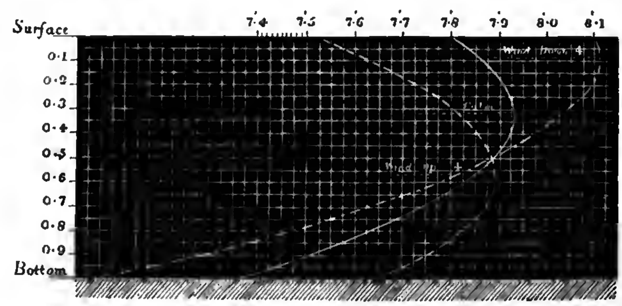

FIG. 106.

It is impossible at present to give a theoretical rule for the vertical velocity curve, but in very many gaugings it has been found that a parabola with horizontal axis fits the observed results fairly well. The mean velocity on any vertical in a stream varies from 0·85 to 0·92 of the surface velocity at that vertical, and on the average if v_o is the surface and v_m the mean velocity at a vertical $v_m = \frac{6}{7}v_o$, a result useful in float gauging. On any vertical there is a point at which the velocity is equal to the mean velocity, and if this point were known it would be useful in gauging. Humphreys and Abbot in the Mississippi found the mean velocity at 0·66 of the depth; G. H. L. Hagen and H. Heinemann at 0·56 to 0·58 of the depth. The mean of observations by various observers gave the mean velocity at from 0·587 to 0·62 of the depth, the average of all being almost exactly 0·6 of the depth. The mid-depth velocity is therefore nearly equal to, but a little greater than, the mean velocity on a vertical. If v_{md} is the mid-depth velocity, then on the average $v_m = 0{\cdot}98v_{md}$.

§ 105. *Mean Velocity on a Vertical from Two Velocity Observations.*—A. J. C. Cunningham, in gaugings on the Ganges canal, found the following useful results. Let v_o be the surface, v_m the mean, and v_{xd} the velocity at the depth xd; then

$$v_m = \tfrac{1}{4}(v_o + 3v_{2/3d})$$
$$= \tfrac{1}{2}(v_{\cdot 211d} + v_{\cdot 789d}).$$

§ 106. *Ratio of Mean to Greatest Surface Velocity, for the whole Cross Section in Trapezoidal Channels.*—It is often very important to be able to deduce the mean velocity, and thence the discharge, from observation of the greatest surface velocity. The simplest method of gauging small streams and channels is to observe the greatest surface velocity by floats, and thence to deduce the mean velocity. In general in streams of fairly regular section the mean velocity for the whole section varies from 0·7 to 0·85 of the greatest surface velocity. For channels not widely differing from those experimented on by Bazin, the expression obtained by him for the ratio of surface to mean velocity may be relied on as at least a good approximation to the truth. Let v_o be the greatest surface velocity, v_m the mean velocity of the stream. Then, according to Bazin,

$$v_m = v_o - 25{\cdot}4\sqrt{(mi)}.$$

But

$$v_m = c\sqrt{(mi)},$$

where c is a coefficient, the values of which have been already given in the table in § 98. Hence

$$v_m = cv_o/(c + 25{\cdot}4).$$

Values of Coefficient $c/(c+25{\cdot}4)$ *in the Formula* $v_m = cv_o/(c+25{\cdot}4)$.

§ 107. *River Bends.*—In rivers flowing in alluvial plains, the windings which already exist tend to increase in curvature by the scouring away of material from the outer bank and the deposition of detritus along the inner bank. The sinuosities sometimes increase till a loop is formed with only a narrow strip of land between the two encroaching branches of the river. Finally a "cut off" may occur, a waterway being opened through the strip of land and the loop left separated from the stream, forming a horseshoe shaped lagoon or marsh. Professor James Thomson pointed out (*Proc. Roy. Soc.*, 1877, p. 356; *Proc. Inst. of Mech. Eng.*, 1879, p. 456) that the usual supposition is that the water tending to go forwards in a straight line rushes against the outer bank and scours it, at the same time creating deposits at the inner bank. That view is very far from a complete account of the matter, and Professor Thomson gave a much more ingenious account of the action at the bend, which he completely confirmed by experiment.

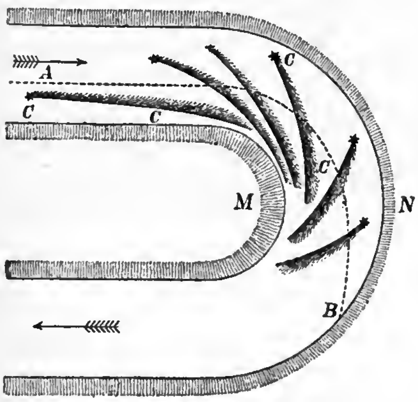

FIG. 107.

When water moves round a circular curve under the action of gravity only, it takes a motion like that in a free vortex. Its velocity is greater parallel to the axis of the stream at the inner than at the outer side of the bend. Hence the scouring at the outer side and the deposit at the inner side of the bend are not due to mere difference of velocity of flow in the general direction of the stream; but, in virtue of the centrifugal force, the water passing round the bend presses outwards, and the free surface in a radial cross section has a slope from the inner side upwards to the outer side (fig. 108). For the greater part of the water flowing in curved paths, this difference of pressure produces no tendency to transverse motion. But the water immediately in contact with the rough bottom and sides of the channel is retarded, and its centrifugal force is insufficient to balance the pressure due to the greater depth at the outside of the bend. It therefore flows inwards towards the inner side of the bend, carrying with it detritus which is deposited at the inner bank. Conjointly with this flow inwards along the bottom and sides, the general mass of water must flow outwards to take its place. Fig. 107 shows the directions of flow as observed in a small artificial stream, by means of light seeds and specks of aniline dye. The lines CC show the directions of flow immediately in contact with the sides and bottom. The dotted line AB shows the direction of motion of floating particles on the surface of the stream.

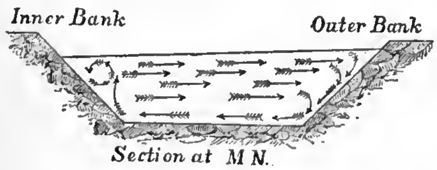

FIG. 108.

§ 108. *Discharge of a River when flowing at different Depths.*—When frequent observations must be made on the flow of a river or canal, the depth of which varies at different times, it is very convenient to have to observe the depth only. A formula can be established giving the flow in terms of the depth. Let Q be the discharge in cubic feet per second; H the depth of the river in some straight and uniform part. Then $Q = aH + bH^2$, where the constants a and b must be found by preliminary gaugings in different conditions of the river. M. C. Moquerey found for part of the upper Saône, $Q = 64{\cdot}7H + 8{\cdot}2H^2$ in metric measures, or $Q = 696H + 26{\cdot}8H^2$ in English measures.

§ 109. *Forms of Section of Channels.*—The simplest form of section for channels is the semicircular or nearly semicircular channel (fig. 109), a form now often adopted from the facility with which it can be executed in concrete. It has the advantage that the rubbing surface is less in proportion to the area than in any other form.

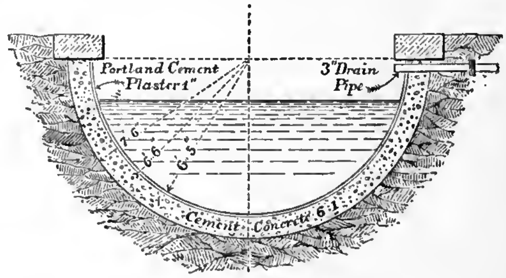

FIG. 109.

Wooden channels or flumes, of which there are examples on a large scale in America, are rectangular in section, and the same form is adopted for wrought and cast-iron aqueducts. Channels built with brickwork or masonry may be also rectangular, but they are often trapezoidal, and are always so if the sides are pitched with masonry laid dry. In a trapezoidal channel, let b (fig. 110) be the bottom breadth, b_0 the top breadth, d the depth, and let the slope of the sides be n horizontal to 1 vertical. Then the area of section is $\Omega = (b+nd)d = (b_0 - nd)d$, and the wetted perimeter $\chi = b + 2d\sqrt{(n^2+1)}$.

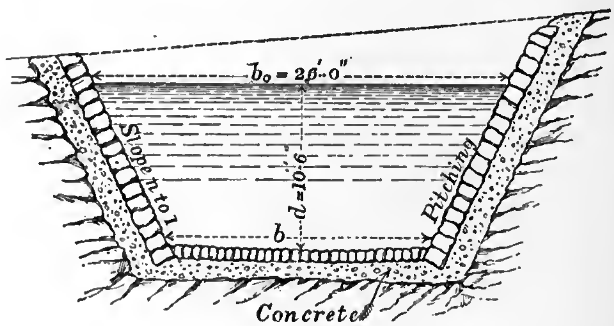

FIG. 110.

When a channel is simply excavated in earth it is always originally trapezoidal, though it becomes more or less rounded in course of time. The slope of the sides then depends on the stability of the earth, a slope of 2 to 1 being the one most commonly adopted.

Figs. 111, 112 show the form of canals excavated in earth, the former being the section of a navigation canal and the latter the section of an irrigation canal.

§ 110. *Channels of Circular Section.*—The following short table facilitates calculations of the discharge with different depths of water in the channel. Let r be the radius of the channel section; then for a depth of water $= \kappa r$, the hydraulic mean radius is μr and the area of section of the waterway νr^2, where κ, μ, and ν have the following values:—

§ 111. *Egg-Shaped Channels or Sewers.*—In sewers for discharging storm water and house drainage the volume of flow is extremely variable; and there is a great liability for deposits to be left when the flow is small, which are not removed during the short periods when the flow is large. The sewer in consequence becomes choked.

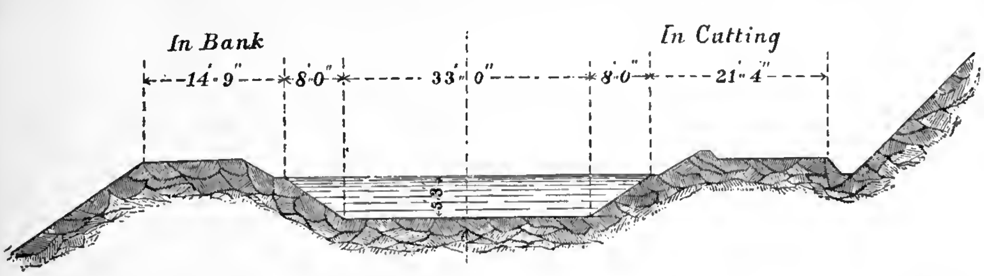

FIG. 111.—Scale 20 ft. = 1 in.

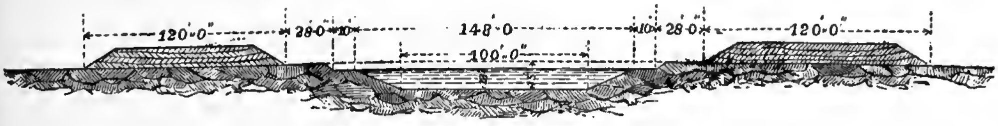

FIG. 112.—Scale 80 ft. = 1 in.

To obtain uniform scouring action, the velocity of flow should be constant or nearly so; a complete uniformity of velocity cannot be obtained with any form of section suitable for sewers, but an approximation to uniform velocity is obtained by making the sewers of oval section. Various forms of oval have been suggested, the simplest being one in which the radius of the crown is double the radius of the invert, and the greatest width is two-thirds the height. The section of such a sewer is shown in fig. 113, the numbers marked on the figure being proportional numbers.

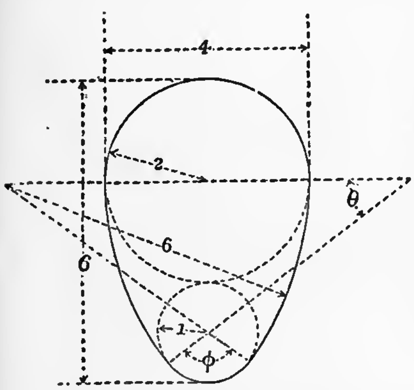

FIG. 113.

§ 112. *Problems on Channels in which the Flow is Steady and at Uniform Velocity.*—The general equations given in §§ 96, 98 are

$$\zeta = \alpha(1+\beta/m); \quad (1)$$
$$\zeta v^2/2g = mi; \quad (2)$$
$$Q = \Omega v. \quad (3)$$

Problem I.—Given the transverse section of stream and discharge, to find the slope. From the dimensions of the section find Ω and m; from (1) find ζ, from (3) find v, and lastly from (2) find i.

Problem II.—Given the transverse section and slope, to find the discharge. Find v from (2), then Q from (3).

Problem III.—Given the discharge and slope, and either the breadth, depth, or general form of the section of the channel, to determine its remaining dimensions. This must generally be solved by approximations. A breadth or depth or both are chosen, and the discharge calculated. If this is greater than the given discharge, the dimensions are reduced and the discharge recalculated.

Since m lies generally between the limits $m=d$ and $m=\frac{1}{2}d$, where d is the depth of the stream, and since, moreover, the velocity varies as $\sqrt{(m)}$ so that an error in the value of m leads only to a much less error in the value of the velocity calculated from it, we may proceed thus. Assume a value for m, and calculate v from it. Let v_1 be this first approximation to v. Then Q/v_1 is a first approximation to Ω, say Ω_1. With this value of Ω design the section of the channel; calculate a second value for m; calculate from it a second value of v, and from that a second value for Ω. Repeat the process till the successive values of m approximately coincide.

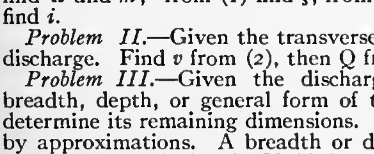

FIG. 114.

§ 113. *Problem IV. Most Economical Form of Channel for given Side Slopes.*—Suppose the channel is to be trapezoidal in section (fig. 114), and that the sides are to have a given slope. Let the longitudinal slope of the stream be given, and also the mean velocity. An infinite number of channels could be found satisfying the foregoing conditions. To render the problem determinate, let it be remembered that, since for a given discharge $\Omega \propto \sqrt[3]{\chi}$, other things being the same, the amount of excavation will be least for that channel which has the least wetted perimeter. Let d be the depth and b the bottom width of the channel, and let the sides slope n horizontal to 1 vertical (fig. 114), then

$$\Omega = (b+nd)d;$$
$$\chi = b+2d\sqrt{(n^2+1)}.$$

Both Ω and χ are to be minima. Differentiating, and equating to zero.

$$(db/dd+n)d+b+nd=0,$$
$$db/dd+2\sqrt{(n^2+1)}=0;$$

eliminating db/dd,

$$\{n-2\sqrt{(n^2+1)}\}d+b+nd=0;$$
$$b=2\{\sqrt{(n^2+1)}-n\}d.$$

But

$$\Omega/\chi = (b+nd)d/\{b+2d\sqrt{(n^2+1)}\}.$$

Inserting the value of b,

$$m=\Omega/\chi = \{2d\sqrt{(n^2+1)}-nd\}/\{4d\sqrt{(n^2+1)}-2nd\} = \tfrac{1}{2}d.$$

That is, with given side slopes, the section is least for a given discharge when the hydraulic mean depth is half the actual depth.

A simple construction gives the form of the channel which fulfils this condition, for it can be shown that when $m=\frac{1}{2}d$ the sides of the channel are tangential to a semicircle drawn on the water line.

Since $\qquad \Omega/\chi = \frac{1}{2}d,$

therefore $\qquad \Omega = \frac{1}{2}\chi d. \qquad (1)$

Let ABCD be the channel (fig. 115); from E the centre of AD drop perpendiculars EF, EG, EH on the sides.

Let

$$AB = CD = a;\ BC = b;\ EF = EH = c;\ \text{and } EG = d.$$
$$\Omega = \text{area } AEB + BEC + CED,$$
$$= ac + \tfrac{1}{2}bd.$$
$$\chi = 2a + b.$$

Putting these values in (1),

$$ac + \tfrac{1}{2}bd = (a+\tfrac{1}{2}b)d; \text{ and hence } c=d.$$

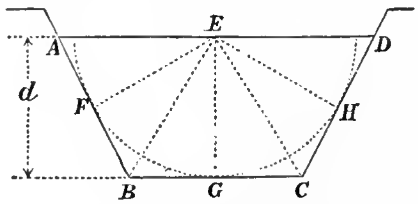

FIG. 115.

That is, EF, EG, EH are all equal, hence a semicircle struck from E with radius equal to the depth of the stream will pass through F and H and be tangential to the sides of the channel.

To draw the channel, describe a semicircle on a horizontal line with radius = depth of channel. The bottom will be a horizontal tangent of that semicircle, and the sides tangents drawn at the required side slopes.

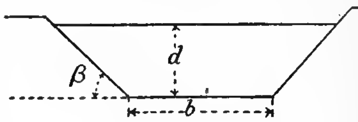

FIG. 116.

The above result may be obtained thus (fig. 116):—

$$\chi = b + 2d/\sin\beta. \qquad (1)$$
$$\Omega = d(b + d\cot\beta);$$
$$\Omega/d = b + d\cot\beta; \qquad (2)$$
$$\Omega/d^2 = b/d + \cot\beta. \qquad (3)$$

From (1) and (2),

$$\chi = \Omega/d - d\cot\beta + 2d/\sin\beta.$$

This will be a minimum for

$$d\chi/dd = \Omega/d^2 + \cot\beta - 2/\sin\beta = 0,$$

or $\qquad \Omega/d^2 = 2\ \text{cosec.}\ \beta - \cot\beta. \qquad (4)$

or $\qquad d = \sqrt{\{\Omega\sin\beta/(2-\cos\beta)\}}.$

From (3) and (4),

$$b/d = 2(1-\cos\beta)/\sin\beta = 2\tan\tfrac{1}{2}\beta.$$

Proportions of Channels of Maximum Discharge for given Area and Side Slopes. Depth of channel $=d$; *Hydraulic mean depth* $=\frac{1}{2}d$; *Area of section* $=\Omega$.

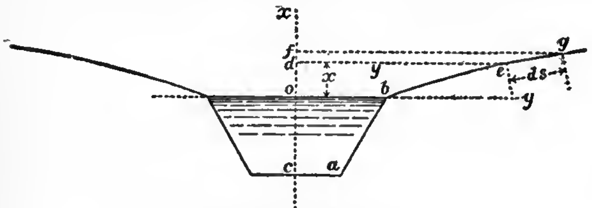
Half the top width is the length of each side slope. The wetted perimeter is the sum of the top and bottom widths

§ 114. *Form of Cross Section of Channel in which the Mean Velocity is Constant with Varying Discharge.*—In designing waste channels from canals, and in some other cases, it is desirable that the mean velocity should be restricted within narrow limits with very different volumes of discharge. In channels of trapezoidal form the velocity increases and diminishes with the discharge. Hence when the discharge is large there is danger of erosion, and when it is small of silting or obstruction by weeds. A theoretical form of section for which the mean velocity would be constant can be found, and, although this is not very suitable for practical purposes, it can be more or less approximated to in actual channels.

Let fig. 117 represent the cross section of the channel. From the symmetry of the section, only half the channel need be considered.



Scale $\frac{1}{10}$ Inch = 1 Foot.

FIG. 117.

Let *obac* be any section suitable for the minimum flow, and let it be required to find the curve *beg* for the upper part of the channel so that the mean velocity shall be constant. Take *o* as origin of coordinates, and let *de*, *fg* be two levels of the water above *ob*.

Let $ob=b/2$; $de=y$, $fg=y+dy$, $od=x$, $of=x+dx$; $eg=ds$.

The condition to be satisfied is that

$$v=c\sqrt{(mi)}$$

should be constant, whether the water-level is at *ob*, *de*, or *fg*. Consequently

$$m=\text{constant}=k$$

for all three sections, and can be found from the section *obac*. Hence also

$$\frac{\text{Increment of section}}{\text{Increment of perimeter}}=\frac{ydx}{ds}=k.$$

$$y^2dx^2=k^2ds^2=k^2(dx^2+dy^2) \text{ and } dx=kdy/\sqrt{(y^2-k^2)}.$$

Integrating,

$$x=k\log_\epsilon\{y+\sqrt{(y^2-k^2)}\}+\text{constant};$$

and, since $y=b/2$ when $x=0$,

$$x=k\log_\epsilon[\{y+\sqrt{(y^2-k^2)}\}/\{\tfrac{1}{2}b+\sqrt{(\tfrac{1}{4}b^2-k^2)}\}].$$

Assuming values for y, the values of x can be found and the curve drawn.

The figure has been drawn for a channel the minimum section of which is a half hexagon of 4 ft. depth. Hence $k=2$; $b=9{\cdot}2$; the rapid flattening of the side slopes is remarkable.

Steady Motion of Water in Open Channels of Varying Cross Section and Slope

§ 115. In every stream the discharge of which is constant, or may be regarded as constant for the time considered, the velocity at different places depends on the slope of the bed. Except at certain exceptional points the velocity will be greater as the slope of the bed is greater, and, as the velocity and cross section of the stream vary inversely, the section of the stream will be least where the velocity and slope are greatest. If in a stream of tolerably uniform slope an obstruction such as a weir is built, that will cause an alteration of flow similar to that of an alteration of the slope of the bed for a greater or less distance above the weir, and the originally uniform cross section of the stream will become a varied one. In such cases it is often of much practical importance to determine the longitudinal section of the stream.

The cases now considered will be those in which the changes of velocity and cross section are gradual and not abrupt, and in which the only internal work which needs to be taken into account is that due to the friction of the stream bed, as in cases of uniform motion. Further, the motion will be supposed to be steady, the mean velocity at each given cross section remaining constant, though it varies from section to section along the course of the stream.

Let fig. 118 represent a longitudinal section of the stream, A_0A_1 being the water surface, B_0B_1 the stream bed. Let A_0B_0, A_1B_1 be

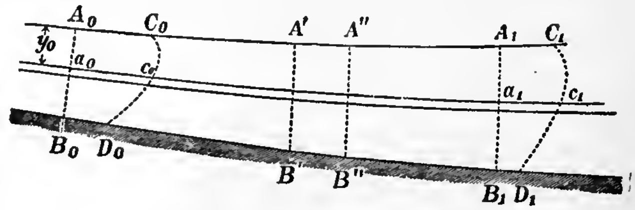


FIG. 118.

cross sections normal to the direction of flow. Suppose the mass of water $A_0B_0A_1B_1$ comes in a short time θ to $C_0D_0C_1D_1$, and let the work done on the mass be equated to its change of kinetic energy during that period. Let l be the length A_0A_1 of the portion of the stream considered, and z the fall of surface level in that distance. Let Q be the discharge of the stream per second.

Change of Kinetic Energy.—At the end of the time θ there are as many particles possessing the same velocities in the space $C_0D_0A_1B_1$ as at the beginning. The change of kinetic energy is therefore the difference of the kinetic energies of $A_0B_0C_0D_0$ and $A_1B_1C_1D_1$.

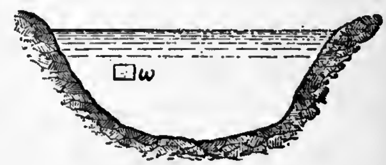

FIG. 119.

Let fig. 119 represent the cross section A_0B_0, and let ω be a small element of its area at a point where the velocity is v. Let Ω_0 be the whole area of the cross section and u_0 the mean velocity for the whole cross section. From the definition of mean velocity we have

$$u_0=\Sigma\omega v/\Omega_0.$$

Let $v=u_0+w$, where w is the difference between the velocity at the small element ω and the mean velocity. For the whole cross section, $\Sigma\omega w=0$.

The mass of fluid passing through the element of section ω, in θ seconds, is $(G/g)\omega v\theta$, and its kinetic energy is $(G/2g)\omega v^3\theta$. For the whole section, the kinetic energy of the mass $A_0B_0C_0D_0$ passing in θ seconds is

$$(G\theta/2g)\Sigma\omega v^3=(G\theta/2g)\Sigma\omega(u_0^3+3u_0^2w+3u_0w^2+w^3),$$
$$=(G\theta/2g)\{u_0^3\Omega+\Sigma\omega w^2(3u_0+w)\}.$$

The factor $3u_0+w$ is equal to $2u_0+v$, a quantity necessarily positive. Consequently $\Sigma\omega v^3>\Omega_0u_0^3$, and consequently the kinetic energy of $A_0B_0C_0D_0$ is greater than

$$(G\theta/2g)\Omega_0u_0^3 \text{ or } (G\theta/2g)Qu_0^2,$$

which would be its value if all the particles passing the section had the same velocity u_0. Let the kinetic energy be taken at

$$\alpha(G\theta/2g)\Omega_0u_0^3=\alpha(G\theta/2g)Qu_0^2,$$

where α is a corrective factor, the value of which was estimated by J. B. C. J. Bélanger at $1{\cdot}1$.[1] Its precise value is not of great importance.

In a similar way we should obtain for the kinetic energy of $A_1B_1C_1D_1$ the expression

$$\alpha(G\theta/2g)\Omega_1u_1^3=\alpha(G\theta/2g)Qu_1^2,$$

where Ω_1, u_1 are the section and mean velocity at A_1B_1, and where α may be taken to have the same value as before without any important error.

Hence the change of kinetic energy in the whole mass $A_0B_0A_1B_1$ in θ seconds is

$$\alpha(G\theta/2g)Q(u_1^2-u_0^2). \qquad (1)$$

Motive Work of the Weight and Pressures.—Consider a small filament a_0a_1 which comes in θ seconds to c_0c_1. The work done by gravity during that movement is the same as if the portion a_0c_0 were carried to a_1c_1. Let $dQ\theta$ be the volume of a_0c_0 or a_1c_1, and y_0, y_1 the depths of a_0, a_1 from the surface of the stream. Then the volume

[1] Boussinesq has shown that this mode of determining the corrective factor α is not satisfactory.

$dQ\theta$ or $GdQ\theta$ pounds falls through a vertical height $z+y_1-y_0$, and the work done by gravity is

$$GdQ\theta(z+y_1-y_0).$$

Putting p_a for atmospheric pressure, the whole pressure per unit of area at a_0 is Gy_0+p_a, and that at a_1 is $-(Gy_1+p_a)$. The work of these pressures is

$$G(y_0+p_a/G-y_1-p_a/G)dQ\theta=G(y_0-y_1)dQ\theta.$$

Adding this to the work of gravity, the whole work is $GzdQ\theta$; or, for the whole cross section,

$$GzQ\theta. \qquad (2)$$

Work expended in Overcoming the Friction of the Stream Bed.—Let A′B′, A″B″ be two cross sections at distances s and $s+ds$ from A_0B_0. Between these sections the velocity may be treated as uniform, because by hypothesis the changes of velocity from section to section are gradual. Hence, to this short length of stream the equation for uniform motion is applicable. But in that case the work in overcoming the friction of the stream bed between A′B′ and A″B″ is

$$GQ\theta\zeta(u^2/2g)(\chi/\Omega)ds,$$

where u, χ, Ω are the mean velocity, wetted perimeter, and section at A′B′. Hence the whole work lost in friction from A_0B_0 to A_1B_1 will be

$$GQ\theta\int_0^l\zeta(u^2/2g)(\chi/\Omega)ds. \qquad (3)$$

Equating the work given in (2) and (3) to the change of kinetic energy given in (1),

$$\alpha(GQ\theta/2g)\ (u_1^2-u_0^2)=GQz\theta-GQ\theta\textstyle\int_0^l\zeta(u^2/2g)(\chi/\Omega)ds;$$

$$\therefore z=\alpha(u_1^2-u_0^2)/2g+\int_0^l\zeta(u^2/2g)(\chi/\Omega)ds.$$

§ 116. *Fundamental Differential Equation of Steady Varied Motion.*—Suppose the equation just found to be applied to an indefinitely short length ds of the stream, limited by the end sections ab, a_1b_1, taken for simplicity normal to the stream bed (fig. 120). For that short length of stream the fall of surface level, or difference of level of

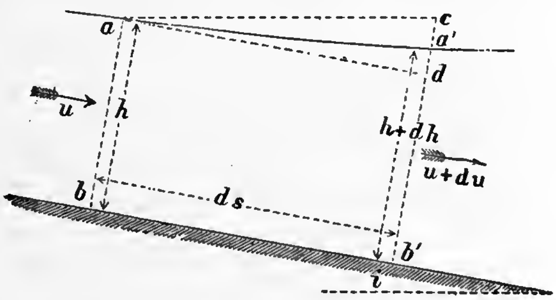

FIG. 120.

a and a_1, may be written dz. Also, if we write u for u_0, and $u+du$ for u_1, the term $(u_0^2-u_1^2)/2g$ becomes udu/g. Hence the equation applicable to an indefinitely short length of the stream is

$$dz=udu/g+(\chi/\Omega)\zeta(u^2/2g)ds. \qquad (1)$$

From this equation some general conclusions may be arrived at as to the form of the longitudinal section of the stream, but, as the investigation is somewhat complicated, it is convenient to simplify it by restricting the conditions of the problem.

Modification of the Formula for the Restricted Case of a Stream flowing in a Prismatic Stream Bed of Constant Slope.—Let i be the constant slope of the bed. Draw ad parallel to the bed, and ac horizontal. Then dz is sensibly equal to $a'c$. The depths of the stream, h and $h+dh$, are sensibly equal to ab and $a'b'$, and therefore $dh=a'd$. Also cd is the fall of the bed in the distance ds, and is equal to ids. Hence

$$dz=a'c=cd-a'd=ids-dh. \qquad (2)$$

Since the motion is steady—

$$Q=\Omega u=\text{constant}.$$

Differentiating,

$$\Omega du+ud\Omega=0;$$
$$\therefore du=-ud\Omega/\Omega.$$

Let x be the width of the stream, then $d\Omega=xdh$ very nearly. Inserting this value,

$$du=-(ux/\Omega)dh. \qquad (3)$$

Putting the values of du and dz found in (2) and (3) in equation (1),

$$ids-dh=-(u^2x/g\Omega)dh+(\chi/\Omega)\zeta(u^2/2g)ds.$$
$$dh/ds=\{i-(\chi/\Omega)\zeta(u^2/2g)\}/\{1-(u^2/g)(x/\Omega).\} \qquad (4)$$

Further Restriction to the Case of a Stream of Rectangular Section and of Indefinite Width.—The equation might be discussed in the form just given, but it becomes a little simpler if restricted in the way just stated. For, if the stream is rectangular, $xh=\Omega$, and if x is large compared with h, $\Omega/\chi=xh/x=h$ nearly. Then equation (4) becomes

$$dh/ds=i(1-\zeta u^2/2gih)/(1-u^2/gh). \qquad (5)$$

§ 117. *General Indications as to the Form of Water Surface furnished by Equation* (5).—Let A_0A_1 (fig. 121) be the water surface, B_0B_1 the bed in a longitudinal section of the stream, and ab any section at a distance s from B_0, the depth ab being h. Suppose B_0B_1, B_0A_0 taken as rectangular coordinate axes, then dh/ds is the trigonometric tangent of the angle which the surface of the stream at a makes with the axis B_0B_1. This tangent dh/ds will be positive, if the stream is increasing in depth in the direction B_0B_1; negative,

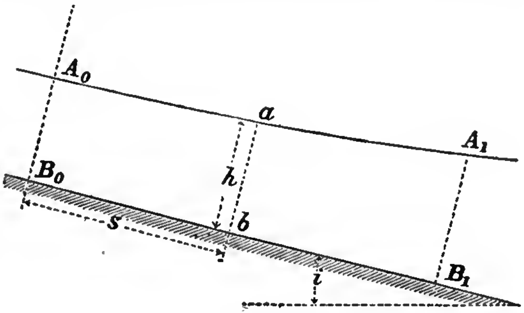

FIG. 121.

if the stream is diminishing in depth from B_0 towards B_1. If $dh/ds=0$, the surface of the stream is parallel to the bed, as in cases of uniform motion. But from equation (4)

$$dh/ds=0,\ \text{if}\ i-(\chi/\Omega)\zeta(u^2/2g)=0;$$
$$\therefore\zeta(u^2/2g)=(\Omega/\chi)i=mi,$$

which is the well-known general equation for uniform motion, based on the same assumptions as the equation for varied steady motion now being considered. The case of uniform motion is therefore a limiting case between two different kinds of varied motion.

Consider the possible changes of value of the fraction

$$(1-\zeta u^2/2gih)/(1-u^2/gh).$$

As h tends towards the limit 0, and consequently u is large, the numerator tends to the limit $-\infty$. On the other hand if $h=\infty$, in which case u is small, the numerator becomes equal to 1. For a value H of h given by the equation

$$1-\zeta u^2/2gi\text{H}=0,$$
$$\text{H}=\zeta u^2/2gi,$$

we fall upon the case of uniform motion. The results just stated may be tabulated thus:—

For $h=0$, H, $>$H, ∞,
the numerator has the value $-\infty$, 0, $>$ 0, 1.

Next consider the denominator. If h becomes very small, in which case u must be very large, the denominator tends to the limit $-\infty$. As h becomes very large and u consequently very small, the denominator tends to the limit 1. For $h=u^2/g$, or $u=\sqrt{(gh)}$, the denominator becomes zero. Hence, tabulating these results as before:—

For $h=0$, u^2/g, $>u^2/g$, ∞,
the denominator becomes $-\infty$, 0, $>$ 0, 1.

§ 118. *Case* 1.—Suppose $h>u^2/g$, and also $h>$H, or the depth greater than that corresponding to uniform motion. In this case dh/ds is positive, and the stream increases in depth in the direction of flow. In fig. 122 let B_0B_1 be the bed, C_0C_1 a line parallel to the bed and at a height above it equal to H. By hypothesis, the surface

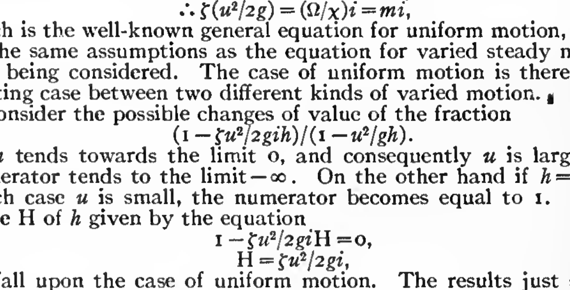

FIG. 122.

A_0A_1 of the stream is above C_0C_1, and it has just been shown that the depth of the stream increases from B_0 towards B_1. But going up stream h approaches more and more nearly the value H, and therefore dh/ds approaches the limit 0, or the surface of the stream is asymptotic to C_0C_1. Going down stream h increases and u diminishes, the numerator and denominator of the fraction $(1-\zeta u^2/2gih)/(1-u^2/gh)$ both tend towards the limit 1, and dh/ds to the limit i. That is, the surface of the stream tends to become asymptotic to a horizontal line D_0D_1.

The form of water surface here discussed is produced when the flow of a stream originally uniform is altered by the construction of a weir. The raising of the water surface above the level C_0C_1 is termed the backwater due to the weir.

§ 119. *Case* 2.—Suppose $h>u^2/g$, and also $h<$H. Then dh/ds is negative, and the stream is diminishing in depth in the direction of flow. In fig. 123 let B_0B_1 be the stream bed as before; C_0C_1 a line drawn parallel to B_0B_1 at a height above it equal to H. By hypothesis the surface A_0A_1 of the stream is below C_0C_1, and the depth has just been shown to diminish from B_0 towards B_1. Going up stream h approaches the limit H, and dh/ds tends to the limit zero. That is, up stream A_0A_1 is asymptotic to C_0C_1. Going down stream h diminishes and u increases; the inequality $h>u^2/g$ diminishes; the denominator of the fraction $(1-\zeta u^2/2gih)/(1-u^2/gh)$ tends to the limit zero, and consequently dh/ds tends to ∞. That is, down stream A_0A_1 tends to a direction perpendicular to the bed. Before, however, this limit was reached the assumptions on which the general equation is based would cease to be even approximately true, and the equation would cease to be applicable. The filaments would have a relative motion, which would make the influence of internal friction in the fluid too important to be neglected. A stream surface of this form may be produced if there is an abrupt fall in the bed of the stream (fig. 124).

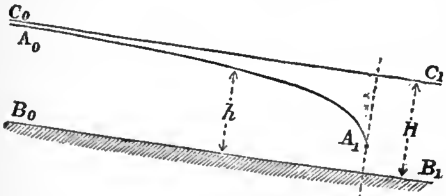

FIG. 123.

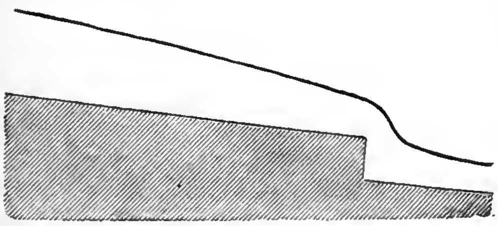

FIG. 124.

On the Ganges canal, as originally constructed, there were abrupt falls precisely of this kind, and it appears that the lowering of the water surface and increase of velocity which such falls occasion, for a distance of some miles up stream, was not foreseen. The result was that, the velocity above the falls being greater than was intended, the bed was scoured and considerable damage was done to the works. "When the canal was first opened the water was allowed to pass freely over the crests of the overfalls, which were laid on the level of the bed of the earthen channel; erosion of bed and sides for some miles up rapidly followed, and it soon became apparent that means must be adopted for raising the surface of the stream at those points (that is, the crests of the falls). Planks were accordingly fixed in the grooves above the bridge arches, or temporary weirs were formed over which the water was allowed to fall; in some cases the surface of the water was thus raised above its normal height, causing a backwater in the channel above" (Crofton's *Report on the Ganges Canal*, p. 14). Fig. 125 represents in an exaggerated form what probably occurred, the diagram being intended

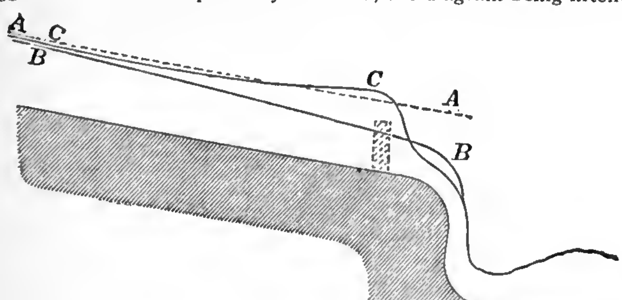

FIG. 125.

to represent some miles' length of the canal bed above the fall. AA parallel to the canal bed is the level corresponding to uniform motion with the intended velocity of the canal. In consequence of the presence of the ogee fall, however, the water surface would take some such form as BB, corresponding to Case 2 above, and the velocity would be greater than the intended velocity, nearly in the inverse ratio of the actual to the intended depth. By constructing a weir on the crest of the fall, as shown by dotted lines, a new water surface CC corresponding to Case 1 would be produced, and by suitably choosing the height of the weir this might be made to agree approximately with the intended level AA.

§ 120. *Case* 3.—Suppose a stream flowing uniformly with a depth $h<u^2/g$. For a stream in uniform motion $\zeta u^2/2g=mi$, or if the stream is of indefinitely great width, so that $m=\text{H}$, then $\zeta u^2/2g=i\text{H}$, and $\text{H}=\zeta u^2/2gi$. Consequently the condition stated above involves that

$$\zeta u^2/2gi<u^2/g, \text{ or that } i>\zeta/2.$$

If such a stream is interfered with by the construction of a weir which raises its level, so that its depth at the weir becomes $h_1>u^2/g$, then for a portion of the stream the depth h will satisfy the conditions $h<u^2/g$ and $h>\text{H}$, which are not the same as those assumed in the two previous cases. At some point of the stream above the weir the depth h becomes equal to u^2/g, and at that point dh/ds becomes infinite, or the surface of the stream is normal to the bed. It is obvious that at that point the influence of internal friction will be too great to be neglected, and the general equation will cease to represent the true conditions of the motion of the water. It is known that, in cases such as this, there occurs an abrupt rise of the free surface of the stream, or a standing wave is formed, the conditions of motion in which will be examined presently.

It appears that the condition necessary to give rise to a standing wave is that $i>\zeta/2$. Now ζ depends for different channels on the roughness of the channel and its hydraulic mean depth. Bazin calculated the values of ζ for channels of different degrees of roughness and different depths given in the following table, and the corresponding minimum values of i for which the exceptional case of the production of a standing wave may occur.

Nature of Bed of Stream.	Slope below which a Standing Wave is impossible in feet per foot.	Standing Wave Formed.	
		Slope in feet per foot.	Least Depth in feet.
Very smooth cemented surface	0·00147	0·002	0·262
		0·003	·098
		0·004	·065
Ashlar or brickwork . . .	0·00186	0·003	·394
		0·004	·197
		0·006	·098
Rubble masonry	0·00235	0·004	1·181
		0·006	·525
		0·010	·262
Earth	0·00275	0·006	3·478
		0·010	1·542
		0·015	·919

STANDING WAVES

§ 121. The formation of a standing wave was first observed by Bidone. Into a small rectangular masonry channel, having a slope of 0·023 ft. per foot, he admitted water till it flowed uniformly with a depth of 0·2 ft. He then placed a plank across the stream which raised the level just above the obstruction to 0·95 ft. He found that the stream above the obstruction was sensibly unaffected up to a point 15 ft. from it. At that point the depth suddenly increased from 0·2 ft. to 0·56 ft. The velocity of the stream in the part unaffected by the obstruction was 5·54 ft. per second. Above the point where the abrupt change of depth occurred $u^2=5{\cdot}54^2=30{\cdot}7$, and $gh=32{\cdot}2\times0{\cdot}2=6{\cdot}44$; hence u^2 was$>gh$. Just below the abrupt change of depth $u=5{\cdot}54\times0{\cdot}2/0{\cdot}56=1{\cdot}97$; $u^2=3{\cdot}88$; and $gh=32{\cdot}2\times0{\cdot}56=18{\cdot}03$; hence at this point $u^2<gh$. Between these two points, therefore, $u^2=gh$; and the condition for the production of a standing wave occurred.

The change of level at a standing wave may be found thus. Let fig. 126 represent the longitudinal section of a stream and ab, cd

FIG. 126.

cross sections normal to the bed, which for the short distance considered may be assumed horizontal. Suppose the mass of water $abcd$ to come to $a'b'c'd'$ in a short time t; and let u_0, u_1 be the velocities at ab and cd, Ω_0, Ω_1 the areas of the cross sections. The force causing change of momentum in the mass $abcd$ estimated horizontally is simply the difference of the pressures on ab and cd. Putting h_0, h_1 for the depths of the centres of gravity of ab and cd measured down from the free water surface, the force is $\text{G}(h_0\Omega_0-h_1\Omega_1)$ pounds, and the impulse in t seconds is $\text{G}\ (h_0\Omega_0-h_1\Omega_1)\ t$ second pounds. The horizontal change of momentum is the difference of the momenta of $cdc'd'$ and $aba'b'$; that is,

$$(\text{G}/g)(\Omega_1u_1^2-\Omega_0u_0^2)t.$$

Hence, equating impulse and change of momentum,

$$G(h_0\Omega_0 - h_1\Omega_1)t = (G/g)(\Omega_1 u_1^2 - \Omega_0 u_0^2)t;$$
$$\therefore\ h_0\Omega_0 - h_1\Omega_1 = (\Omega_1 u_1^2 - \Omega_0 u_0^2)/g. \qquad (1)$$

For simplicity let the section be rectangular, of breadth B and depths H_0 and H_1, at the two cross sections considered; then $h_0 = \frac{1}{2}H_0$, and $h_1 = \frac{1}{2}H_1$. Hence

$$H_0^2 - H_1^2 = (2/g)(H_1 u_1^2 - H_0 u_0^2).$$

But, since $\Omega_0 u_0 = \Omega_1 u_1$, we have

$$u_1^2 = u_0^2 H_0^2/H_1^2,$$
$$H_0^2 - H_1^2 = (2u_0^2/g)(H_0^2/H_1 - H_0). \qquad (2)$$

This equation is satisfied if $H_0 = H_1$, which corresponds to the case of uniform motion. Dividing by $H_0 - H_1$, the equation becomes

$$(H_1/H_0)(H_0 + H_1) = 2u_0^2/g; \qquad (3)$$
$$\therefore\ H_1 = \sqrt{(2u_0^2 H_0/g + \tfrac{1}{4}H_0^2)} + \tfrac{1}{2}H_0. \qquad (4)$$

In Bidone's experiment $u_0 = 5{\cdot}54$, and $H = 0{\cdot}2$. Hence $H_1 = 0{\cdot}52$, which agrees very well with the observed height.

§ 122. A standing wave is frequently produced at the foot of a weir. Thus in the ogee falls originally constructed on the Ganges canal a standing wave was observed as shown in fig. 127. The water falling over the weir crest A acquired a very high velocity on the

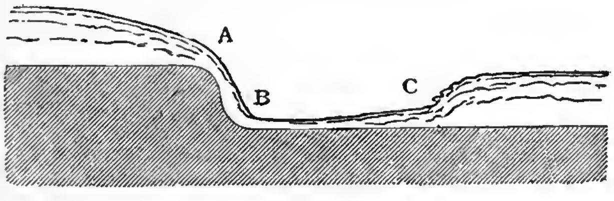

FIG. 127.

steep slope AB, and the section of the stream at B became very small. It easily happened, therefore, that at B the depth $h < u^2/g$. In flowing along the rough apron of the weir the velocity u diminished and the depth h increased. At a point C, where h became equal to u^2/g, the conditions for producing the standing wave occurred. Beyond C the free surface abruptly rose to the level corresponding to uniform motion with the assigned slope of the lower reach of the canal.

A standing wave is sometimes formed on the down stream side of bridges the piers of which obstruct the flow of the water. Some interesting cases of this kind are described in a paper on the "Floods in the Nerbudda Valley" in the *Proc. Inst. Civ. Eng.* vol. xxvii. p. 222, by A. C. Howden. Fig. 128 is compiled from the data given in that paper. It represents the section of the stream at pier 8 of the Towah Viaduct, during the flood of 1865. The ground level is not exactly given by Howden, but has been inferred from data given on another drawing. The velocity of the stream was not observed, but the author states it was probably the same as at the Gunjal river during a similar flood, that is 16·58 ft. per second. Now, taking the depth on the down stream face of the pier at 26 ft., the velocity necessary for the production of a standing wave would be $u = \sqrt{(gh)} = \sqrt{(32{\cdot}2 \times 26)} = 29$ ft. per second nearly. But the velocity at this point was probably from Howden's statements $16{\cdot}58 \times \frac{40}{26} = 25{\cdot}5$ ft., an agreement as close as the approximate character of the data would lead us to expect.

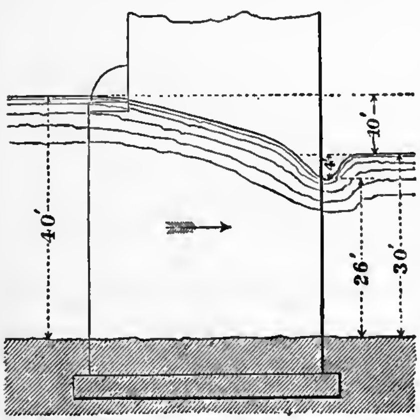

FIG. 128.

XI. ON STREAMS AND RIVERS

§ 123. *Catchment Basin.*—A stream or river is the channel for the discharge of the available rainfall of a district, termed its catchment basin. The catchment basin is surrounded by a ridge or watershed line, continuous except at the point where the river finds an outlet. The area of the catchment basin may be determined from a suitable contoured map on a scale of at least 1 in 100,000. Of the whole rainfall on the catchment basin, a part only finds its way to the stream. Part is directly re-evaporated, part is absorbed by vegetation, part may escape by percolation into neighbouring districts. The following table gives the relation of the average stream discharge to the average rainfall on the catchment basin (Tiefenbacher).

	Ratio of average Discharge to average Rainfall.	Loss by Evaporation, &c., in per cent of total Rainfall.
Cultivated land and spring-forming declivities	·3 to ·33	67 to 70
Wooded hilly slopes	·35 to ·45	55 to 65
Naked unfissured mountains	·55 to ·60	40 to 45

§ 124. *Flood Discharge.*—The flood discharge can generally only be determined by examining the greatest height to which floods have been known to rise. To produce a flood the rainfall must be heavy and widely distributed, and to produce a flood of exceptional height the duration of the rainfall must be so great that the flood waters of the most distant affluents reach the point considered, simultaneously with those from nearer points. The larger the catchment basin the less probable is it that all the conditions tending to produce a maximum discharge should simultaneously occur. Further, lakes and the river bed itself act as storage reservoirs during the rise of water level and diminish the rate of discharge, or serve as flood moderators. The influence of these is often important, because very heavy rain storms are in most countries of comparatively short duration. Tiefenbacher gives the following estimate of the flood discharge of streams in Europe:—

	Flood discharge of Streams per Second per Square Mile of Catchment Basin.
In flat country	8·7 to 12·5 cub. ft.
In hilly districts	17·5 to 22·5 „
In moderately mountainous districts	36·2 to 45·0 „
In very mountainous districts	50·0 to 75·0 „

It has been attempted to express the decrease of the rate of flood discharge with the increase of extent of the catchment basin by empirical formulae. Thus Colonel P. P. L. O'Connell proposed the formula $y = M\sqrt{x}$, where M is a constant called the modulus of the river, the value of which depends on the amount of rainfall, the physical characters of the basin, and the extent to which the floods are moderated by storage of the water. If M is small for any given river, it shows that the rainfall is small, or that the permeability or slope of the sides of the valley is such that the water does not drain rapidly to the river, or that lakes and river bed moderate the rise of the floods. If values of M are known for a number of rivers, they may be used in inferring the probable discharge of other similar rivers. For British rivers M varies from 0·43 for a small stream draining meadow land to 37 for the Tyne. Generally it is about 15 or 20. For large European rivers M varies from 16 for the Seine to 67·5 for the Danube. For the Nile M = 11, a low value which results from the immense length of the Nile throughout which it receives no affluent, and probably also from the influence of lakes. For different tributaries of the Mississippi M varies from 13 to 56. For various Indian rivers it varies from 40 to 303, this variation being due to the great variations of rainfall, slope and character of Indian rivers.

In some of the tank projects in India, the flood discharge has been calculated from the formula $D = C\sqrt[3]{n^2}$, where D is the discharge in cubic yards per hour from n square miles of basin. The constant C was taken = 61,523 in the designs for the Ekrooka tank, = 75,000 on Ganges and Godavery works, and = 10,000 on Madras works.

§ 125. *Action of a Stream on its Bed.*—If the velocity of a stream exceeds a certain limit, depending on its size, and on the size, heaviness, form and coherence of the material of which its bed is composed, it scours its bed and carries forward the materials. The quantity of material which a given stream can carry in suspension depends on the size and density of the particles in suspension, and is greater as the velocity of the stream is greater. If in one part of its course the velocity of a stream is great enough to scour the bed and the water becomes loaded with silt, and in a subsequent part of the river's course the velocity is diminished, then part of the transported material must be deposited. Probably deposit and scour go on simultaneously over the whole river bed, but in some parts the rate of scour is in excess of the rate of deposit, and in other parts the rate of deposit is in excess of the rate of scour. Deep streams appear to have the greatest scouring power at any given velocity. It is possible that the difference is strictly a difference of transporting, not of scouring action. Let fig. 129 represent a section of a stream. The material lifted at a will be diffused through the mass of the stream and deposited at different distances down stream. The average path of a particle lifted at a will be some such curve as abc, and the average distance of transport each time a particle is lifted

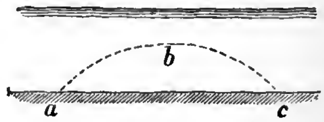

FIG. 129.

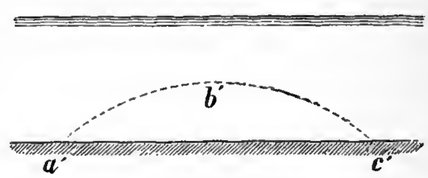

FIG. 130.

will be represented by ac. In a deeper stream such as that in fig. 130, the average height to which particles are lifted, and, since the rate of vertical fall through the water may be assumed the same as before, the average distance $a'c'$ of transport will be greater. Consequently, although the scouring action may be identical in the two streams, the velocity of transport of material down stream is greater as the depth of the stream is greater. The effect is that the deep stream excavates its bed more rapidly than the shallow stream.

§ 126. *Bottom Velocity at which Scour commences.*—The following bottom velocities were determined by P. L. G. Dubuat to be the maximum velocities consistent with stability of the stream bed for different materials.

Darcy and Bazin give, for the relation of the mean velocity v_m and bottom velocity v_b.

$$v_m = v_b + 10\cdot87\sqrt{(mi)}.$$

But

$$\sqrt{mi} = v_m\sqrt{(\zeta/2g)};$$

$$\therefore v_m = v_b/(1 - 10\cdot87\sqrt{(\zeta/2g)}).$$

Taking a mean value for ζ, we get

$$v_m = 1\cdot312 v_b,$$

and from this the following values of the mean velocity are obtained:—

	Bottom Velocity $=v_b$.	Mean Velocity $=v_m$.
1. Soft earth	0·25	·33
2. Loam	0·50	·65
3. Sand	1·00	1·30
4. Gravel	2·00	2·62
5. Pebbles	3·40	4·46
6. Broken stone, flint	4·00	5·25
7. Chalk, soft shale	5·00	6·56
8. Rock in beds	6·00	7·87
9. Hard rock	10·00	13·12

The following table of velocities which should not be exceeded in channels is given in the *Ingenieurs Taschenbuch* of the Verein "Hütte":—

	Surface Velocity.	Mean Velocity.	Bottom Velocity.
Slimy earth or brown clay	·49	·36	·26
Clay	·98	·75	·52
Firm sand	1·97	1·51	1·02
Pebbly bed	4·00	3·15	2·30
Boulder bed	5·00	4·03	3·08
Conglomerate of slaty fragments	7·28	6·10	4·90
Stratified rocks	8·00	7·45	6·00
Hard rocks	14·00	12·15	10·36

§ 127. *Regime of a River Channel.*—A river channel is said to be in a state of regime, or stability, when it changes little in draught or form in a series of years. In some rivers the deepest part of the channel changes its position perpetually, and is seldom found in the same place in two successive years. The sinuousness of the river also changes by the erosion of the banks, so that in time the position of the river is completely altered. In other rivers the change from year to year is very small, but probably the regime is never perfectly stable except where the rivers flow over a rocky bed.

If a river had a constant discharge it would gradually modify its bed till a permanent regime was established. But as the volume

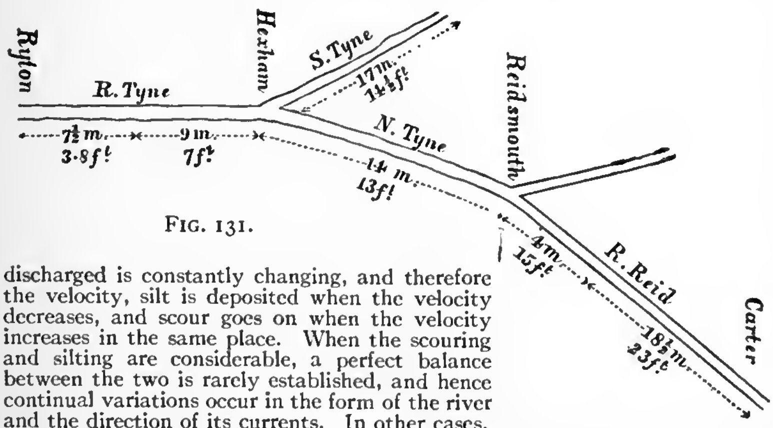

FIG. 131.

discharged is constantly changing, and therefore the velocity, silt is deposited when the velocity decreases, and scour goes on when the velocity increases in the same place. When the scouring and silting are considerable, a perfect balance between the two is rarely established, and hence continual variations occur in the form of the river and the direction of its currents. In other cases, where the action is less violent, a tolerable balance may be established, and the deepening of the bed by scour at one time is compensated by the silting at another. In that case the general regime is permanent, though alteration is constantly going on. This is more likely to happen if by artificial means the erosion of the banks is prevented. If a river flows in soil incapable of resisting its tendency to scour it is necessarily sinuous (§ 107), for the slightest deflection of the current to either side begins an erosion which increases progressively till a considerable bend is formed. If such a river is straightened it becomes sinuous again unless its banks are protected from scour.

§ 128. *Longitudinal Section of River Bed.*—The declivity of rivers decreases from source to mouth. In their higher parts rapid and torrential, flowing over beds of gravel or boulders, they enlarge in volume by receiving affluent streams, their slope diminishes, their bed consists of smaller materials, and finally they reach the sea. Fig. 131 shows the length in miles, and the surface fall in feet per mile, of the Tyne and its tributaries.

The decrease of the slope is due to two causes. (1) The action of the transporting power of the water, carrying the smallest debris the greatest distance, causes the bed to be less stable near the mouth than in the higher parts of the river; and, as the river adjusts its slope to the stability of the bed by scouring or increasing its sinuousness when the slope is too great, and by silting or straightening its course if the slope is too small, the decreasing stability of the bed would coincide with a decreasing slope. (2) The increase of volume and section of the river leads to a decrease of slope; for the larger the section the less slope is necessary to ensure a given velocity.

The following investigation, though it relates to a purely arbitrary case, is not without interest. Let it be assumed, to make the conditions definite—(1) that a river flows over a bed of uniform resistance to scour, and let it be further assumed that to maintain stability the velocity of the river in these circumstances is constant from source to mouth; (2) suppose the sections of the river at all points are similar, so that, b being the breadth of the river at any point, its hydraulic mean depth is ab and its section is cb^2, where a and c are constants applicable to all parts of the river; (3) let us further assume that the discharge increases uniformly in consequence of the supply from affluents, so that, if l is the length of the river from its source to any given point, the discharge there will be kl, where k is another constant applicable to all points in the course of the river.

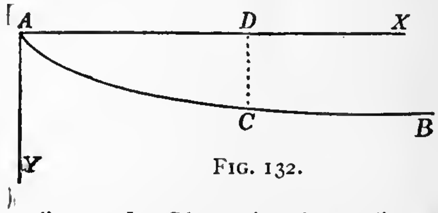

FIG. 132.

Let AB (fig. 132) be the longitudinal section of the river, whose source is at A; and take A for the origin of vertical and horizontal coordinates. Let C be a point whose ordinates are x and y, and let the river at C have the breadth b, the slope i, and the velocity v.

Since velocity $\times$ area of section = discharge, $vcb^2 = kl$, or $b = \sqrt{(kl/cv)}$.

Hydraulic mean depth $= ab = a\sqrt{(kl/cv)}$.

But, by the ordinary formula for the flow of rivers, $mi = \zeta v^2$;

$$\therefore i = \zeta v^2/m = (\zeta v^{\frac{3}{2}}/a)\sqrt{(c/kl)}.$$

But i is the tangent of the angle which the curve at C makes with the axis of X, and is therefore $= dy/dx$. Also, as the slope is small, $l = \mathrm{AC} = \mathrm{AD} = x$ nearly.

$$\therefore dy/dx = (\zeta v^{\frac{3}{2}}/a)\sqrt{(c/kx)};$$

and, remembering that v is constant,

$$y = (2\zeta v^{\frac{3}{2}}/a)\sqrt{(cx/k)};$$

or

$$y^2 = \text{constant} \times x;$$

so that the curve is a common parabola, of which the axis is horizontal and the vertex at the source. This may be considered an ideal longitudinal section, to which actual rivers approximate more or less, with exceptions due to the varying hardness of their beds, and the irregular manner in which their volume increases.

§ 129. *Surface Level of River.*—The surface level of a river is a plane changing constantly in position from changes in the volume of water discharged, and more slowly from changes in the river bed, and the circumstances affecting the drainage into the river.

For the purposes of the engineer, it is important to determine (1) the extreme low water level, (2) the extreme high water or flood level, and (3) the highest navigable level.

1. *Low Water Level* cannot be absolutely known, because a river reaches its lowest level only at rare intervals, and because alterations in the cultivation of the land, the drainage, the removal of forests, the removal or erection of obstructions in the river bed, &c., gradually alter the conditions of discharge. The lowest level of which records can be found is taken as the conventional or approximate low water level, and allowance is made for possible changes.

2. *High Water or Flood Level.*—The engineer assumes as the highest flood level the highest level of which records can be obtained. In forming a judgment of the data available, it must be remembered that the highest level at one point of a river is not always simultaneous

with the attainment of the highest level at other points, and that the rise of a river in flood is very different in different parts of its course. In temperate regions, the floods of rivers seldom rise more than 20 ft. above low-water level, but in the tropics the rise of floods is greater.

3. *Highest Navigable Level.*—When the river rises above a certain level, navigation becomes difficult from the increase of the velocity of the current, or from submersion of the tow paths, or from the headway under bridges becoming insufficient. Ordinarily the highest navigable level may be taken to be that at which the river begins to overflow its banks.

§ 130. *Relative Value of Different Materials for Submerged Works.*—That the power of water to remove and transport different materials depends on their density has an important bearing on the selection of materials for submerged works. In many cases, as in the aprons or floorings beneath bridges, or in front of locks or falls, and in the formation of training walls and breakwaters by *pierres perdus*, which have to resist a violent current, the materials of which the structures are composed should be of such a size and weight as to be able individually to resist the scouring action of the water. The heaviest materials will therefore be the best; and the different value of materials in this respect will appear much more striking, if it is remembered that all materials lose part of their weight in water. A block whose volume is V cubic feet, and whose density in air is w lb per cubic foot, weighs in air wV lb, but in water only $(w-62{\cdot}4)$ V lb.

	Weight of a Cub. Ft. in lb.	
	In Air.	In Water.
Basalt	187·3	124·9
Brick	130·0	67·6
Brickwork	112·0	49·6
Granite and limestone	170·0	107·6
Sandstone	144·0	81·6
Masonry	116-144	53·6-81·6

§ 131. *Inundation Deposits from a River.*—When a river carrying silt periodically overflows its banks, it deposits silt over the area flooded, and gradually raises the surface of the country. The silt is deposited in greatest abundance where the water first leaves the river. It hence results that the section of the country assumes a peculiar form, the river flowing in a trough along the crest of a ridge, from which the land slopes downwards on both sides. The silt deposited from the water forms two wedges, having their thick ends towards the river (fig. 133).

Fig. 133.

This is strikingly the case with the Mississippi, and that river is now kept from flooding immense areas by artificial embankments or levees. In India, the term *deltaic segment* is sometimes applied to that portion of a river running through deposits formed by inundation, and having this characteristic section. The irrigation of the country in this case is very easy; a comparatively slight raising of the river surface by a weir or annicut gives a command of level which permits the water to be conveyed to any part of the district.

§ 132. *Deltas.*—The name delta was originally given to the Δ-shaped portion of Lower Egypt, included between seven branches of the Nile. It is now given to the whole of the alluvial tracts round river mouths formed by deposition of sediment from the river, where its velocity is checked on its entrance to the sea. The characteristic feature of these alluvial deltas is that the river traverses them, not in a single channel, but in two or many bifurcating branches. Each branch has a tract of the delta under its influence, and gradually raises the surface of that tract, and extends it seaward. As the delta extends itself seaward, the conditions of discharge through the different branches change. The water finds the passage through one of the branches less obstructed than through the others; the velocity and scouring action in that branch are increased; in the others they diminish. The one channel gradually absorbs the whole of the water supply, while the other branches silt up. But as the mouth of the new main channel extends seaward the resistance increases both from the greater length of the channel and the formation of shoals at its mouth, and the river tends to form new bifurcations AC or AD (fig. 134), and one of these may in time become the main channel of the river.

§ 133. *Field Operations preliminary to a Study of River Improvement.*—There are required (1) a plan of the river, on which the positions of lines of levelling and cross sections are marked; (2) a longitudinal section and numerous cross sections of the river; (3) a series of gaugings of the discharge at different points and in different conditions of the river.

Longitudinal Section.—This requires to be carried out with great accuracy. A line of stakes is planted, following the sinuosities of the river, and chained and levelled. The cross sections are referred to the line of stakes, both as to position and direction. The determination of the surface slope is very difficult, partly from its extreme smallness, partly from oscillation of the water. Cunningham recommends that the slope be taken in a length of 2000 ft. by four simultaneous observations, two on each side of the river.

§ 134. *Cross Sections.*—A stake is planted flush with the water, and its level relatively to some point on the line of levels is determined. Then the depth of the water is determined at a series of points (if

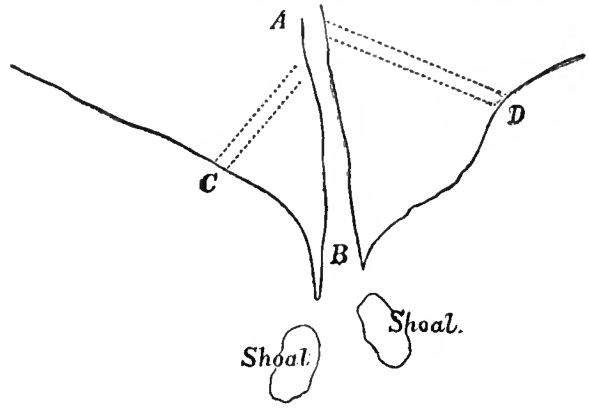

Fig. 134.

possible at uniform distances) in a line starting from the stake and perpendicular to the thread of the stream. To obtain these, a wire may be stretched across with equal distances marked on it by hanging tags. The depth at each of these tags may be obtained by a light wooden staff, with a disk-shaped shoe 4 to 6 in. in diameter. If the depth is great, soundings may be taken by a chain and weight. To ensure the wire being perpendicular to the thread of the stream, it is desirable to stretch two other wires similarly graduated, one above and the other below, at a distance of 20 to 40 yds. A number of floats being then thrown in, it is observed whether they pass the same graduation on each wire.

For large and rapid rivers the cross section is obtained by sounding in the following way. Let AC (fig. 135) be the line on which soundings are required. A base line AB is measured out at right angles to AC, and ranging staves are set up at AB and at D in line with AC. A boat is allowed to drop down stream, and, at the moment it comes in line with AD, the lead is dropped, and an observer in the boat takes, with a box sextant, the angle AEB subtended by AB. The sounding line may have a weight of 14 lb of lead, and, if the boat drops down stream slowly, it may hang near the bottom, so that the observation is made instantly. In extensive surveys of the Mississippi observers with theodolites were stationed at A and B. The theodolite at A was directed towards C, that at B was kept on the boat. When the boat came on the line AC, the observer at A signalled, the sounding line was dropped, and the observer at B read off the angle ABE. By repeating observations a number of soundings are obtained, which can be plotted in their proper position, and the form of the river bed drawn by connecting the extremities of the lines. From the section can be measured the sectional area of the stream Ω and its wetted perimeter χ; and from these the hydraulic mean depth m can be calculated.

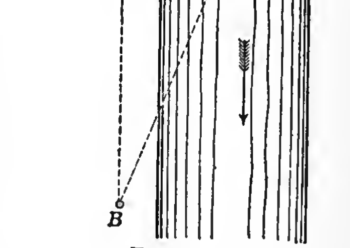

Fig. 135.

§ 135. *Measurement of the Discharge of Rivers.*—The area of cross section multiplied by the mean velocity gives the discharge of the stream. The height of the river with reference to some fixed mark should be noted whenever the velocity is observed, as the velocity and area of cross section are different in differest states of the river. To determine the mean velocity various methods may be adopted; and, since no method is free from liability to error, either from the difficulty of the observations or from uncertainty as to the ratio of the mean velocity to the velocity observed, it is desirable that more than one method should be used.

Instruments for Measuring the Velocity of Water

§ 136. *Surface Floats* are convenient for determining the surface velocities of a stream, though their use is difficult near the banks. The floats may be small balls of wood, of wax or of hollow metal, so loaded as to float nearly flush with the water surface. To render them visible they may have a vertical painted stem. In experiments on the Seine, cork balls $1\frac{3}{4}$ in. diameter were used, loaded to float flush with the water, and provided with a stem. In A. J. C. Cunningham's observations at Roorkee, the floats were thin circular disks of English deal, 3 in. diameter and $\frac{1}{4}$ in. thick. For observations near the banks, floats 1 in. diameter and $\frac{1}{8}$ in. thick were used. To render them visible a tuft of cotton wool was used loosely fixed in a hole at the centre.

The velocity is obtained by allowing the float to be carried down, and noting the time of passage over a measured length of the stream. If v is the velocity of any float, t the time of passing over a length l, then $v=l/t$. To mark out distinctly the length of stream over which the floats pass, two ropes may be stretched across the stream at a distance apart, which varies usually from 50 to 250 ft., according to the size and rapidity of the river. In the Roorkee experiments a length of run of 50 ft. was found best for the central two-fifths of the width, and 25 ft. for the remainder, except very close to the banks, where the run was made $12\frac{1}{2}$ ft. only. The longer the run the less is the proportionate error of the time observations, but on the other hand the greater the deviation of the floats from a straight course parallel to the axis of the stream. To mark the precise position at which the floats cross the ropes, Cunningham used short white rope pendants, hanging so as nearly to touch the surface of the water. In this case the streams were 80 to 180 ft. in width. In wider streams the use of ropes to mark the length of run is impossible, and recourse must be had to box sextants or theodolites to mark the path of the floats.

Let AB (fig. 136) be a measured base line strictly parallel to the thread of the stream, and AA_1, BB_1 lines at right angles to AB marked out by ranging rods at A_1 and B_1. Suppose observers stationed at A and B with sextants or theodolites, and let CD be the path of any float down stream. As the float approaches AA_1, the observer at B keeps it on the cross wire of his instrument. The observer at A observes the instant of the float reaching the line AA_1, and signals to B who then reads off the angle ABC. Similarly, as the float approaches BB_1, the observer at A keeps it in sight, and when signalled to by B reads the angle BAD. The data so obtained are sufficient for plotting the path of the float and determining the distances AC, BD.

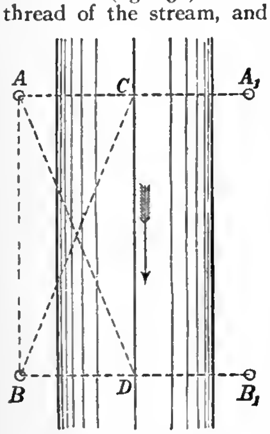

FIG. 136.

The time taken by the float in passing over the measured distance may be observed by a chronograph, started as the float passes the upper rope or line, and stopped when it passes the lower. In Cunningham's observations two chronometers were sometimes used, the time of passing one end of the run being noted on one, and that of passing the other end of the run being noted on the other. The chronometers were compared immediately before the observations. In other cases a single chronometer was used placed midway of the run. The moment of the floats passing the ends of the run was signalled to a timekeeper at the chronometer by shouting. It was found quite possible to count the chronometer beats to the nearest half second, and in some cases to the nearest quarter second.

§ 137. *Sub-surface Floats.*—The velocity at different depths below the surface of a stream may be obtained by sub-surface floats, used precisely in the same way as surface floats. The most usual arrangement is to have a large float, of slightly greater density than water, connected with a small and very light surface float. The motion of the combined arrangement is not sensibly different from that of the large float, and the small surface float enables an observer to note the path and velocity of the sub-surface float. The instrument is, however, not free from objection. If the large submerged float is made of very nearly the same density as water, then it is liable to be thrown upwards by very slight eddies in the water, and it does not maintain its position at the depth at which it is intended to float. On the other hand, if the large float is made sensibly heavier than water, the indicating or surface float must be made rather large, and then it to some extent influences the motion of the submerged float. Fig. 137 shows one form of sub-surface float. It consists of a couple of tin plates bent at a right angle and soldered together at the angle. This is connected with a wooden ball at the surface by a very thin wire or cord. As the tin alone makes a heavy submerged float, it is better to attach to the tin float some pieces of wood to diminish its weight in water. Fig. 138 shows the form of submerged float used by Cunningham. It consists of a hollow metal ball connected to a slice of cork, which serves as the surface float.

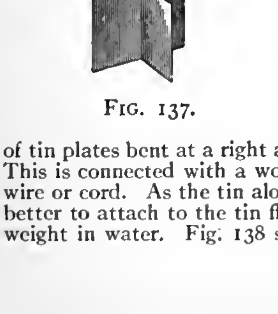

FIG. 137.

§ 138. *Twin Floats.*—Suppose two equal and similar floats (fig. 139) connected by a wire. Let one float be a little lighter and the other a little heavier than water. Then the velocity of the combined floats will be the mean of the surface velocity and the velocity at the depth at which the heavier float swims, which is determined by the length of the connecting wire. Thus if v_s is the surface velocity and v_d the velocity at the depth to which the lower float is sunk, the velocity of the combined floats will be

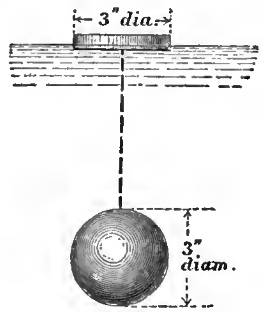

FIG. 138.

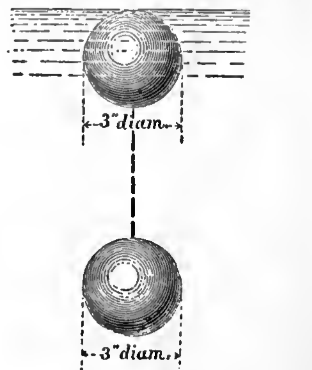

FIG. 139.

$$v=\tfrac{1}{2}(v_s+v_d).$$

Consequently, if v is observed, and v_s determined by an experiment with a single float,

$$v_d=2v-v_s.$$

According to Cunningham, the twin float gives better results than the sub-surface float.

§ 139. *Velocity Rods.*—Another form of float is shown in fig. 140. This consists of a cylindrical rod loaded at the lower end so as to float nearly vertical in water. A wooden rod, with a metal cap at the bottom in which shot can be placed, answers better than anything else, and sometimes the wooden rod is made in lengths, which can be screwed together so as to suit streams of different depths. A tuft of cotton wool at the top serves to make the float more easily visible. Such a rod, so adjusted in length that it sinks nearly to the bed of the stream, gives directly the mean velocity of the whole vertical section in which it floats.

FIG. 140.

§ 140. *Revy's Current Meter.*—No instrument has been so much used in directly determining the velocity of a stream at a given point as the screw current meter. Of this there are a dozen varieties at least. As an example of the instrument in its simplest form, Revy's meter may be selected. This is an ordinary screw meter of a larger size than usual, more carefully made, and with its details carefully studied (figs. 141, 142). It was designed after experience in gauging the great South American rivers. The screw, which is actuated by the water, is 6 in. in diameter, and is of the type of the Griffiths screw used in ships. The hollow spherical boss serves to make the weight of the screw sensibly equal to its displacement, so that friction is much reduced. On the axis *aa* of the screw is a worm which drives the counter. This consists of two worm wheels *g* and *h* fixed on a common axis. The worm wheels are carried on a frame attached to the pin *l*. By means of a string attached to *l* they can be pulled into gear with the worm, or dropped out of gear and stopped at any instant. A nut *m* can be screwed up, if necessary, to keep the counter permanently in gear. The worm is two-threaded, and the worm wheel *g* has 200 teeth. Consequently it makes one rotation for 100 rotations of the screw, and the number of rotations up to 100 is marked by the passage of the graduations on its edge in front of a fixed index. The second worm wheel has 196 teeth, and its edge is divided into 49 divisions. Hence it falls behind the first wheel one division for a complete rotation of the latter. The number of hundreds of rotations of the screw are therefore shown by the number of divisions on *h* passed over by an index fixed to *g*. One difficulty in the use of the ordinary screw meter is that particles of grit, getting into the working parts, very sensibly alter the friction, and therefore the speed of the meter. Revy obviates this by enclosing the counter in a brass box with a glass face. This box is filled with pure water, which ensures a constant coefficient of friction for the rubbing parts, and prevents any mud or grit finding its way in. In order that the meter may place itself with the axis parallel to the current, it is pivoted on a vertical axis and directed by a large vane shown in fig. 142. To give the vane more directing power the vertical axis is nearer the screw than in ordinary meters, and the vane is larger. A second horizontal vane is attached by the screws x, x, the object of which is to allow the meter to rest on the ground without the motion of the screw being interfered with. The string or wire for starting and stopping the meter is

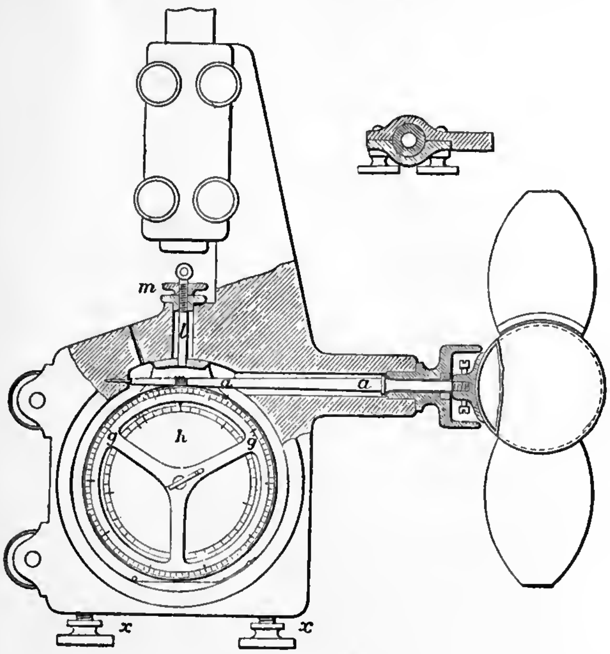

FIG. 141.—Scale ½ full size.

carried through the centre of the vertical axis, so that the strain on it may not tend to pull the meter oblique to the current. The pitch of the screw is about 9 in. The screws at x serve for filling the meter with water. The whole apparatus is fixed to a rod (fig. 142), of a length proportionate to the depth, or for very great depths it is fixed to a weighted bar lowered by ropes, a plan invented by Revy. The instrument is generally used thus. The reading of the counter is noted, and it is put out of gear. The meter is then lowered into the water to the required position from a platform between two boats, or better from a temporary bridge. Then the counter is put into gear for one, two or five minutes. Lastly, the instrument is raised and the counter again read. The velocity is deduced from the number of rotations in unit time by the formulae given below. For surface velocities the counter may be kept permanently in gear, the screw being started and stopped by hand.

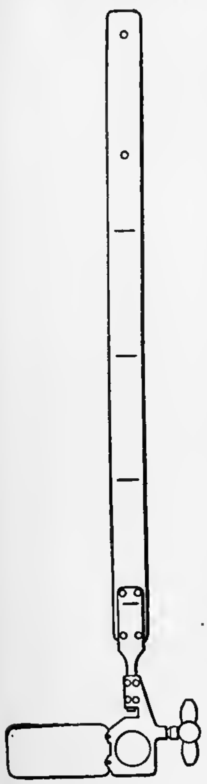

FIG. 142.

§ 141. *The Harlacher Current Meter.*—In this the ordinary counting apparatus is abandoned. A worm drives a worm wheel, which makes an electrical contact once for each 100 rotations of the worm. This contact gives a signal above water. With this arrangement, a series of velocity observations can be made, without removing the instrument from the water, and a number of practical difficulties attending the accurate starting and stopping of the ordinary counter are entirely got rid of. Fig. 143 shows the meter. The worm wheel z makes one rotation for 100 of the screw. A pin moving the lever x makes the electrical contact. The wires b, c are led through a gas pipe B; this also serves to adjust the meter to any required position on the wooden rod dd. The rudder or vane is shown at WH. The galvanic current acts on the electromagnet m, which is fixed in a small metal box containing also the battery. The magnet exposes and withdraws a coloured disk at an opening in the cover of the box.

§ 142. *Amsler Laffon Current Meter.*—A very convenient and accurate current meter is constructed by Amsler Laffon of Schaffhausen. This can be used on a rod, and put into and out of gear by a ratchet. The peculiarity in this case is that there is a double ratchet, so that one pull on the string puts the counter into gear and a second puts it out of gear. The string may be slack during the action of the meter, and there is less uncertainty than when the counter has to be held in gear. For deep streams the meter A is suspended by a wire with a heavy lenticular weight below (fig. 144). The wire is payed out from a small winch D, with an index showing the depth of the meter, and passes over a pulley B. The meter is in gimbals and is directed by a conical rudder which keeps it facing the stream with its axis horizontal. There is an electric circuit from a battery C through the meter, and a contact is made closing the circuit every 100 revolutions. The moment the circuit closes a bell rings. By a subsidiary arrangement, when the foot of the instrument, 0·3 metres below the axis of the meter, touches the ground the circuit is also closed and the bell rings. It is easy to distinguish the continuous ring when the ground is reached from the short ring when the counter signals. A convenient winch for the wire is so graduated that if

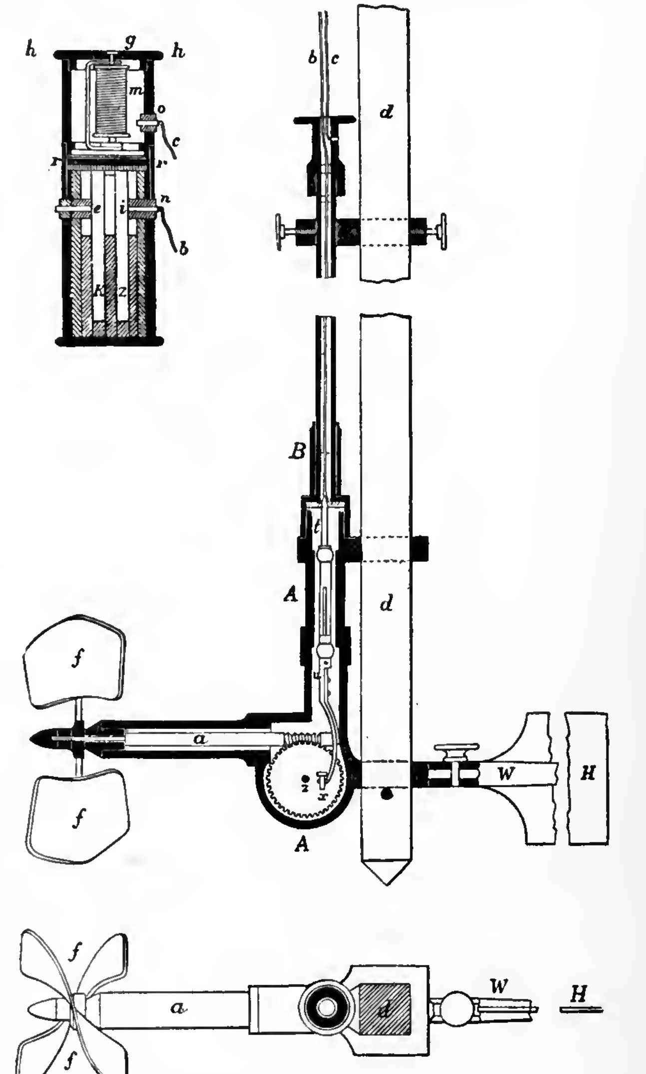

FIG. 143.

set when the axis of the meter is at the water surface it indicates at any moment the depth of the meter below the surface. Fig. 144 shows the meter as used on a boat. It is a very convenient instrument for obtaining the velocity at different depths and can also be used as a sounding instrument.

§ 143. *Determination of the Coefficients of the Current Meter.*—Suppose a series of observations has been made by towing the meter in still water at different speeds, and that it is required to ascertain from these the constants of the meter. If v is the velocity of the water and n the observed number of rotations per second, let

$$v=\alpha+\beta n \qquad (1)$$

where α and β are constants. Now let the meter be towed over a measured distance L, and let N be the revolutions of the meter and t the time of transit. Then the speed of the meter relatively to the water is $L/t=v$ feet per second, and the number of revolutions per second is $N/t=n$. Suppose m observations have been made in this way, furnishing corresponding values of v and n, the speed in each trial being as uniform as possible,

$$\Sigma n=n_1+n_2+\ .\ .\ .$$
$$\Sigma v=v_1+v_2+\ .\ .\ .$$
$$\Sigma nv=n_1v_1+n_2v_2+\ .\ .\ .$$
$$\Sigma n^2=n_1^2+n_2^2+\ .\ .\ .$$
$$[\Sigma n]^2=[n_1+n_2+\ .\ .\ .]^2$$

Then for the determination of the constants α and β in (1), by the method of least squares—

$$\alpha = \frac{\Sigma n^2 \Sigma v - \Sigma n \Sigma n v}{m \Sigma n^2 - [\Sigma n]^2},$$

$$\beta = \frac{m \Sigma n v - \Sigma v \Sigma n}{m \Sigma n^2 - [\Sigma n]^2}.$$

In a few cases the constants for screw current meters have been determined by towing them in R. E. Froude's experimental tank in which the resistance of ship models is ascertained. In that case the data are found with exceptional accuracy.

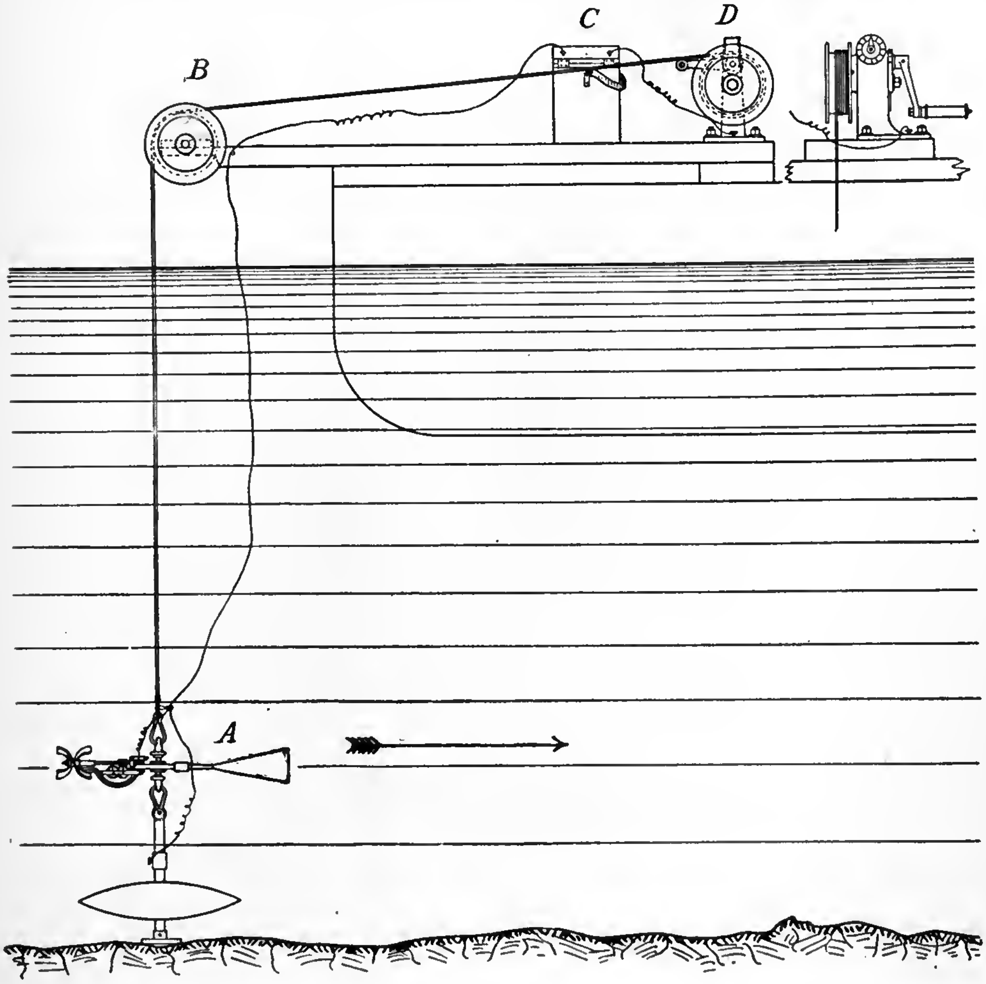

FIG. 144.

§ 144. *Darcy Gauge or modified Pitot Tube.*—A very old instrument for measuring velocities, invented by Henri Pitot in 1730 (*Histoire de l'Académie des Sciences*, 1732, p. 376), consisted simply of a vertical glass tube with a right-angled bend, placed so that its mouth was normal to the direction of flow (fig. 145).

The impact of the stream on the mouth of the tube balances a column in the tube, the height of which is approximately $h = v^2/2g$, where v is the velocity at the depth x. Placed with its mouth parallel to the stream the water inside the tube is nearly at the same level as the surface of the stream, and turned with the mouth down stream, the fluid sinks a depth $h' = v^2/2g$ nearly, though the tube in that case interferes with the free flow of the liquid and somewhat modifies the result. Pitot expanded the mouth of the tube so as to form a funnel or bell mouth. In that case he found by experiment

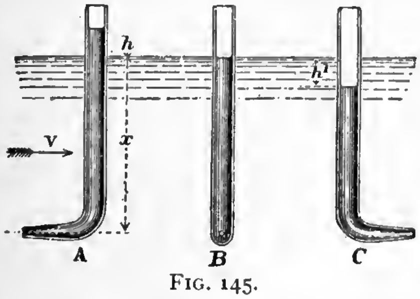

FIG. 145.

$$h = 1 \cdot 5v^2/2g.$$

But there is more disturbance of the stream. Darcy preferred to make the mouth of the tube very small to avoid interference with the stream and to check oscillations of the water column. Let the difference of level of a pair of tubes A and B (fig. 145) be taken to be $h = kv^2/2g$, then k may be taken to be a corrective coefficient whose value in well-shaped instruments is very nearly unity. By placing his instrument in front of a boat towed through water Darcy found $k = 1 \cdot 034$; by placing the instrument in a stream the velocity of which had been ascertained by floats, he found $k = 1 \cdot 006$; by readings taken in different parts of the section of a canal in which a known volume of water was flowing, he found $k = 0 \cdot 993$. He believed the first value to be too high in consequence of the disturbance caused by the boat. The mean of the other two values is almost exactly unity (*Recherches hydrauliques*, Darcy and Bazin, 1865, p. 63). W. B. Gregory used somewhat differently formed Pitot tubes for which the $k = 1$ (*Am. Soc. Mech. Eng.*, 1903, 25). T. E. Stanton used a Pitot tube in determining the velocity of an air current, and for his instrument he found $k = 1 \cdot 030$ to $k = 1 \cdot 032$ ("On the Resistance of Plane Surfaces in a Current of Air," *Proc. Inst. Civ. Eng.*, 1904, 156).

One objection to the Pitot tube in its original form was the great difficulty and inconvenience of reading the height h in the immediate neighbourhood of the stream surface. This is obviated in the Darcy gauge, which can be removed from the stream to be read.

Fig. 146 shows a Darcy gauge. It consists of two Pitot tubes having their mouths at right angles. In the instrument shown, the two tubes, formed of copper in the lower part, are united into one for strength, and the mouths of the tubes open vertically and horizontally. The upper part of the tubes is of glass, and they are provided with a brass scale and two verniers b, b. The whole instrument is supported on a vertical rod or small pile AA, the fixing at B permitting the instrument to be adjusted to any height on the rod, and at the same time allowing free rotation, so that it can be held parallel to the current. At c is a two-way cock, which can be opened or closed by cords. If this is shut, the instrument can be lifted out of the stream for reading. The glass tubes are connected at top by a brass fixing, with a stop cock a, and a flexible tube and mouthpiece m. The use of this is as follows. If the velocity is required at a point near the surface of the stream, one at least of the water columns would be below the level at which it could be read. It would be in the copper part of the instrument. Suppose then a little air is sucked out by the tube m, and the cock a closed, the two columns will be forced up an amount corresponding to the difference between atmospheric pressure and that in the tubes. But the difference of level will remain unaltered.

When the velocities to be measured are not very small, this instrument is an admirable one. It requires observation only of a single linear quantity, and does not require any time observation. The law connecting the velocity and the observed height is a rational one, and it is not absolutely necessary to make any experiments on the coefficient of the instrument. If we take $v = k\sqrt{(2gh)}$, then it appears from Darcy's experiments that for a well-formed instrument k does not sensibly differ from unity. It gives the velocity at a definite point in the stream. The chief difficulty arises from the fact that at any given point in a stream the velocity is not absolutely constant, but varies a little from moment to moment. Darcy in some of his experiments took several readings, and deduced the velocity from the mean of the highest and lowest.

§ 145. *Perrodil Hydrodynamometer.*—This consists of a frame $abcd$ (fig. 147) placed vertically in the stream, and of a height not less than the stream's depth. The two vertical members of this frame are connected by cross bars, and united above water by a circular bar, situated in the vertical plane and carrying a horizontal graduated circle ef. This whole system is movable round its axis, being suspended on a pivot at g connected with the fixed support mn. Other horizontal arms serve as guides. The central vertical rod gr forms a torsion rod, being fixed at r to the frame $abcd$, and, passing freely upwards through the guides, it carries a horizontal needle moving over the graduated circle *ef*. The support *g*, which carries the apparatus, also receives in a tubular guide the end of the torsion rod *gr* and a set screw for fixing the upper end of the torsion rod when necessary. The impulse of the stream of water is received on a circular disk *x*, in the plane of the torsion rod and the frame *abcd*. To raise and lower the apparatus easily, it is not fixed directly to the rod *mn*, but to a tube *kl* sliding on *mn*.

Suppose the apparatus arranged so that the disk *x* is at that level in the stream where the velocity is to be determined. The plane

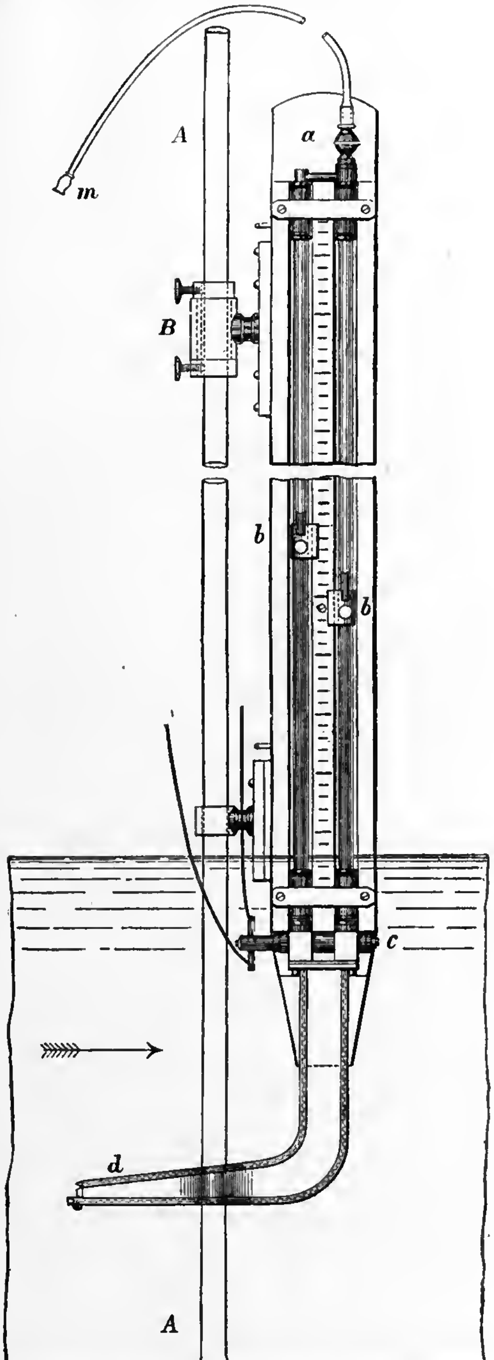

Fig. 146.

abcd is placed parallel to the direction of motion of the water. Then the disk *x* (acting as a rudder) will place itself parallel to the stream on the down stream side of the frame. The torsion rod will be unstrained, and the needle will be at zero on the graduated circle. If, then, the instrument is turned by pressing the needle, till the plane *abcd* of the disk and the zero of the graduated circle is at right angles to the stream, the torsion rod will be twisted through an angle which measures the normal impulse of the stream on the disk *x*. That angle will be given by the distance of the needle from zero. Observation shows that the velocity of the water at a given point is not constant. It varies between limits more or less wide. When the apparatus is nearly in its right position, the set screw at *g* is made to clamp the torsion spring. Then the needle is fixed, and the apparatus carrying the graduated circle oscillates. It is not, then, difficult to note the mean angle marked by the needle.

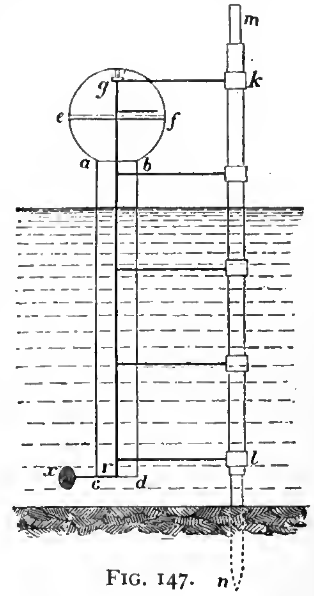

Fig. 147.

Let r be the radius of the torsion rod, l its length from the needle over *ef* to r, and α the observed torsion angle. Then the moment of the couple due to the molecular forces in the torsion rod is

$$M = E_t I \alpha / l;$$

where E_t is the modulus of elasticity for torsion, and I the polar moment of inertia of the section of the rod. If the rod is of circular section, $I = \frac{1}{2}\pi r^4$. Let R be the radius of the disk, and b its leverage, or the distance of its centre from the axis of the torsion rod. The moment of the pressure of the water on the disk is

$$Fb = kb(G/2g)\pi R^2 v^2,$$

where G is the heaviness of water and k an experimental coefficient. Then

$$E_t I \alpha / l = kb(G/2g)\pi R^2 v^2.$$

For any given instrument,

$$v = c\sqrt{\alpha},$$

where c is a constant coefficient for the instrument.

The instrument as constructed had three disks which could be used at will. Their radii and leverages were in feet

	R =	b =
1st disk	0·052	0·16
2nd ,,	0·105	0·32
3rd ,,	0·210	0·66

For a thin circular plate, the coefficient $k = 1 \cdot 12$. In the actual instrument the torsion rod was a brass wire 0·06 in. diameter and $6\frac{1}{2}$ ft. long. Supposing α measured in degrees, we get by calculation

$$v = 0 \cdot 335\sqrt{\alpha};\ 0 \cdot 115\sqrt{\alpha};\ 0 \cdot 042\sqrt{\alpha}.$$

Very careful experiments were made with the instrument. It was fixed to a wooden turning bridge, revolving over a circular channel of 2 ft. width, and about 76 ft. circumferential length. An allowance was made for the slight current produced in the channel. These experiments gave for the coefficient c, in the formula $v = c\sqrt{\alpha}$,

1st disk, $c = 0 \cdot 3126$	for velocities of	3 to 16 ft.
2nd ,, 0·1177	,, ,,	$1\frac{1}{4}$ to $3\frac{1}{4}$,,
3rd ,, 0·0349	,, ,,	less than $1\frac{1}{4}$,,

The instrument is preferable to the current meter in giving the velocity in terms of a single observed quantity, the angle of torsion, while the current meter involves the observation of two quantities, the number of rotations and the time. The current meter, except in some improved forms, must be withdrawn from the water to read the result of each experiment, and the law connecting the velocity and number of rotations of a current meter is less well-determined than that connecting the pressure on a disk and the torsion of the wire of a hydrodynamometer.

The Pitot tube, like the hydrodynamometer, does not require a time observation. But, where the velocity is a varying one, and consequently the columns of water in the Pitot tube are oscillating, there is room for doubt as to whether, at any given moment of closing the cock, the difference of level exactly measures the impulse of the stream at the moment. The Pitot tube also fails to give measurable indications of very low velocities.

Processes for Gauging Streams

§ 146. *Gauging by Observation of the Maximum Surface Velocity.*—The method of gauging which involves the least trouble is to determine the surface velocity at the thread of the stream, and to deduce from it the mean velocity of the whole cross section. The maximum surface velocity may be determined by floats or by a current meter. Unfortunately the ratio of the maximum surface to the mean velocity is extremely variable. Thus putting v_o for the surface velocity at the thread of the stream, and v_m for the mean velocity of the whole cross section, v_m/v_o has been found to have the following values:—

	v_m/v_o
De Prony, experiments on small wooden channels	0·8164
Experiments on the Seine	0·62
Destrem and De Prony, experiments on the Neva	0·78
Boileau, experiments on canals	0·82
Baumgartner, experiments on the Garonne	0·80
Brünings (mean)	0·85
Cunningham, Solani aqueduct	0·823

Various formulae, either empirical or based on some theory of the vertical and horizontal velocity curves, have been proposed for determining the ratio v_m/v_o. Bazin found from his experiments the empirical expression

$$v_m = v_o - 25 \cdot 4\sqrt{(mi)};$$

where m is the hydraulic mean depth and i the slope of the stream.

In the case of irrigation canals and rivers, it is often important to determine the discharge either daily or at other intervals of time, while the depth and consequently the mean velocity is varying. Cunningham (*Roorkee Prof. Papers*, iv. 47), has shown that, for a given part of such a stream, where the bed is regular and of permanent section, a simple formula may be found for the variation of the central surface velocity with the depth. When once the constants of this formula have been determined by measuring the central surface velocity and depth, in different conditions of the stream, the surface velocity can be obtained by simply observing the depth of the stream, and from this the mean velocity and discharge can be calculated. Let z be the depth of the stream, and v_o the surface velocity, both measured at the thread of the stream. Then $v_o^2 = cz$; where c is a constant which for the Solani aqueduct had the values 1·9 to 2, the depths being 6 to 10 ft., and the velocities $3\frac{1}{2}$ to $4\frac{1}{2}$ ft. Without any assumption of a formula, however, the surface velocities, or still better the mean velocities, for different conditions of the stream may be plotted on a diagram in which the abscissae are depths and the ordinates velocities. The continuous curve through points so found would then always give the velocity for any observed depth of the stream, without the need of making any new float or current meter observations.

§ 147. *Mean Velocity determined by observing a Series of Surface Velocities.*—The ratio of the mean velocity to the surface velocity in one longitudinal section is better ascertained than the ratio of the central surface velocity to the mean velocity of the whole cross section. Suppose the river divided into a number of compartments by equidistant longitudinal planes, and the surface velocity observed in each compartment. From this the mean velocity in each compartment and the discharge can be calculated. The sum of the partial discharges will be the total discharge of the stream. When wires or ropes can be stretched across the stream, the compartments can be marked out by tags attached to them. Suppose two such ropes stretched across the stream, and floats dropped in above the upper rope. By observing within which compartment the path of the float lies, and noting the time of transit between the ropes, the surface velocity in each compartment can be ascertained. The mean velocity in each compartment is 0·85 to 0·91 of the surface velocity in that compartment. Putting k for this ratio, and $v_1, v_2 \ldots$ for the observed velocities, in compartments of area $\Omega_1, \Omega_2 \ldots$ then the total discharge is

$$Q = k(\Omega_1 v_1 + \Omega_2 v_2 + \ldots).$$

If several floats are allowed to pass over each compartment, the mean of all those corresponding to one compartment is to be taken as the surface velocity of that compartment.

This method is very applicable in the case of large streams or rivers too wide to stretch a rope across. The paths of the floats are then ascertained in this way. Let fig. 148 represent a portion of the river, which should be straight and free from obstructions.

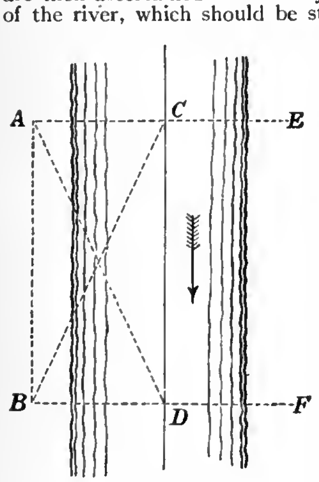

Fig. 148

Suppose a base line AB measured parallel to the thread of the stream, and let the mean cross section of the stream be ascertained either by sounding the terminal cross sections AE, BF, or by sounding a series of equidistant cross sections. The cross sections are taken at right angles to the base line. Observers are placed at A and B with theodolites or box sextants. The floats are dropped in from a boat above AE, and picked up by another boat below BF. An observer with a chronograph or watch notes the time in which each float passes from AE to BF. The method of proceeding is this. The observer A sets his theodolite in the direction AE, and gives a signal to drop a float. B keeps his instrument on the float as it comes down. At the moment the float arrives at C in the line AE, the observer at A calls out. B clamps his instrument and reads off the angle ABC, and the time observer begins to note the time of transit. B now points his instrument in the direction BF, and A keeps the float on the cross wire of his instrument. At the moment the float arrives at D in the line BF, the observer B calls out, A clamps his instrument and reads off the angle BAD, and the time observer notes the time of transit from C to D. Thus all the data are determined for plotting the path CD of the float and determining its velocity. By dropping in a series of floats, a number of surface velocities can be determined. When all these have been plotted, the river can be divided into convenient compartments. The observations belonging to each compartment are then averaged, and the mean velocity and discharge calculated. It is obvious that, as the surface velocity is greatly altered by wind, experiments of this kind should be made in very calm weather.

The ratio of the surface velocity to the mean velocity in the same vertical can be ascertained from the formulae for the vertical velocity curve already given (§ 101). Exner, in *Erbkam's Zeitschrift* for 1875, gave the following convenient formula. Let v be the mean and V the surface velocity in any given vertical longitudinal section, the depth of which is h

$$v/V = (1 + 0 \cdot 1478\sqrt{h})/(1 + 0 \cdot 2216\sqrt{h}).$$

If vertical velocity rods are used instead of common floats, the mean velocity is directly determined for the vertical section in which the rod floats. No formula of reduction is then necessary. The observed velocity has simply to be multiplied by the area of the compartment to which it belongs.

§ 148. *Mean Velocity of the Stream from a Series of Mid Depth Velocities.*—In the gaugings of the Mississippi it was found that the mid depth velocity differed by only a very small quantity from the mean velocity in the vertical section, and it was uninfluenced by wind. If therefore a series of mid depth velocities are determined by double floats or by a current meter, they may be taken to be the mean velocities of the compartments in which they occur, and no formula of reduction is necessary. If floats are used, the method is precisely the same as that described in the last paragraph for surface floats. The paths of the double floats are observed and plotted, and the mean taken of those corresponding to each of the compartments into which the river is divided. The discharge is the sum of the products of the observed mean mid depth velocities and the areas of the compartments.

§ 149. *P. P. Boileau's Process for Gauging Streams.*—Let U be the mean velocity at a given section of a stream, V the maximum velocity, or that of the principal filament, which is generally a little below the surface, W and w the greatest and least velocities at the surface. The distance of the principal filament from the surface is generally less than one-fourth of the depth of the stream; W is a little less than V; and U lies between W and w. As the surface velocities change continuously from the centre towards the sides there are at the surface two filaments having a velocity equal to U. The determination of the position of these filaments, which Boileau terms the gauging filaments, cannot be effected entirely by theory. But, for sections of a stream in which there are no abrupt changes of depth, their position can be very approximately assigned. Let Δ and l be the horizontal distances of the surface filament, having the velocity W, from the gauging filament, which has the velocity U, and from the bank on one side. Then

$$\Delta/l = c^4\sqrt{\{(W+2w)/7(W-w)\}},$$

c being a numerical constant. From gaugings by Humphreys and Abbot, Bazin and Baumgarten, the values $c = 0 \cdot 919$, $0 \cdot 922$ and $0 \cdot 925$ are obtained. Boileau adopts as a mean value $0 \cdot 922$. Hence, if W and w are determined by float gauging or otherwise, Δ can be found, and then a single velocity observation at Δ ft. from the filament of maximum velocity gives, without need of any reduction, the mean velocity of the stream. More conveniently W, w, and U can be measured from a horizontal surface velocity curve, obtained from a series of float observations.

§ 150. *Direct Determination of the Mean Velocity by a Current Meter or Darcy Gauge.*—The only method of determining the mean velocity at a cross section of a stream which involves no assumption of the ratio of the mean velocity to other quantities is this—a plank bridge is fixed across the stream near its surface. From this, velocities are observed at a sufficient number of points in the cross section of the stream, evenly distributed over its area. The mean of these is the true mean velocity of the stream. In Darcy and Bazin's experiments on small streams, the velocity was thus observed at 36 points in the cross section.

When the stream is too large to fix a bridge across it, the observations may be taken from a boat, or from a couple of boats with a gangway between them, anchored successively at a series of points across the width of the stream. The position of the boat for each series of observations is fixed by angular observations to a base line on shore.

§ 151. *A. R. Harlacher's Graphic Method of determining the Discharge from a Series of Current Meter Observations.*—Let ABC (fig. 149) be the cross section of a river at which a complete series of

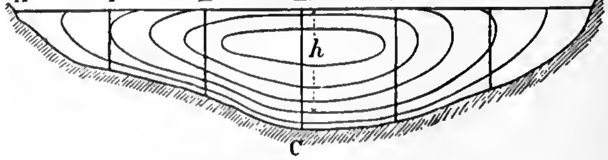

Fig. 149.

current meter observations have been taken. Let I., II., III. . . . be the verticals at different points of which the velocities were measured.

Suppose the depths at I., II., III., . . . (fig. 149), set off as vertical ordinates in fig. 150, and on these vertical ordinates suppose the velocities set off horizontally at their proper depths. Thus, if v is the measured velocity at the depth h from the surface in fig. 149, on vertical marked III., then at III. in fig. 150 take $cd=h$ and $ac=v$. Then d is a point in the vertical velocity curve for the vertical III., and, all the velocities for that ordinate being similarly set off, the curve can be drawn. Suppose all the vertical velocity curves I. . . . V. (fig. 150), thus drawn. On each of these figures draw verticals corresponding to velocities of x, $2x$, $3x$ . . . ft. per second. Then for instance cd at III. (fig. 150) is the depth at which a velocity of $2x$ ft. per second existed on the vertical III. in fig. 149 and if cd is set off at III. in fig. 149 it gives a point in a curve passing through points of the section where the velocity was $2x$ ft. per second. Set off on each of the verticals in fig. 149 all the depths thus found in the corresponding diagram in fig. 150. Curves drawn through the corresponding points on the verticals are curves of equal velocity.

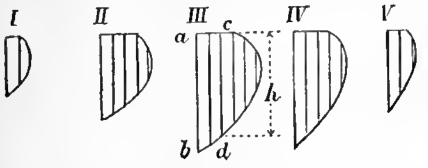

FIG. 150.

The discharge of the stream per second may be regarded as a solid having the cross section of the river (fig. 149) as a base, and cross sections normal to the plane of fig. 149 given by the diagrams in fig. 150. The curves of equal velocity may therefore be considered as contour lines of the solid whose volume is the discharge of the stream per second. Let Ω_0 be the area of the cross section of the river, Ω_1, Ω_2 . . . the areas contained by the successive curves of equal velocity, or, if these cut the surface of the stream, by the curves and that surface. Let x be the difference of velocity for which the successive curves are drawn, assumed above for simplicity at 1 ft. per second. Then the volume of the successive layers of the solid body whose volume represents the discharge, limited by successive planes passing through the contour curves, will be

$$\tfrac{1}{2}x(\Omega_0+\Omega_1),\ \tfrac{1}{2}x(\Omega_1+\Omega_2), \text{ and so on.}$$

Consequently the discharge is

$$Q=x\{\tfrac{1}{2}(\Omega_0+\Omega_n)+\Omega_1=\Omega_2+\ \dots\ +\Omega_{n-1}\}.$$

The areas Ω_0, Ω_1 . . . are easily ascertained by means of the polar planimeter. A slight difficulty arises in the part of the solid lying above the last contour curve. This will have generally a height which is not exactly x, and a form more rounded than the other layers and less like a conical frustum. The volume of this may be estimated separately, and taken to be the area of its base (the area Ω_n) multiplied by $\frac{1}{3}$ to $\frac{1}{2}$ its height.

Fig. 151 shows the results of one of Harlacher's gaugings worked out in this way. The upper figure shows the section of the river and the positions of the verticals at which the soundings and gaugings were taken. The lower gives the curves of equal velocity, worked out from the current meter observations, by the aid of vertical velocity curves. The vertical scale in this figure is ten times as great as in the other. The discharge calculated from the contour curves is 14·1087 cubic metres per second. In the lower figure some other interesting curves are drawn. Thus, the uppermost dotted curve is the curve through points at which the maximum velocity was found; it shows that the maximum velocity was always a little below the surface, and at a greater depth at the centre than at the sides. The next curve shows the depth at which the mean velocity for each vertical was found. The next is the curve of equal velocity corresponding to the mean velocity of the stream; that is, it passes through points in the cross section where the velocity was identical with the mean velocity of the stream.

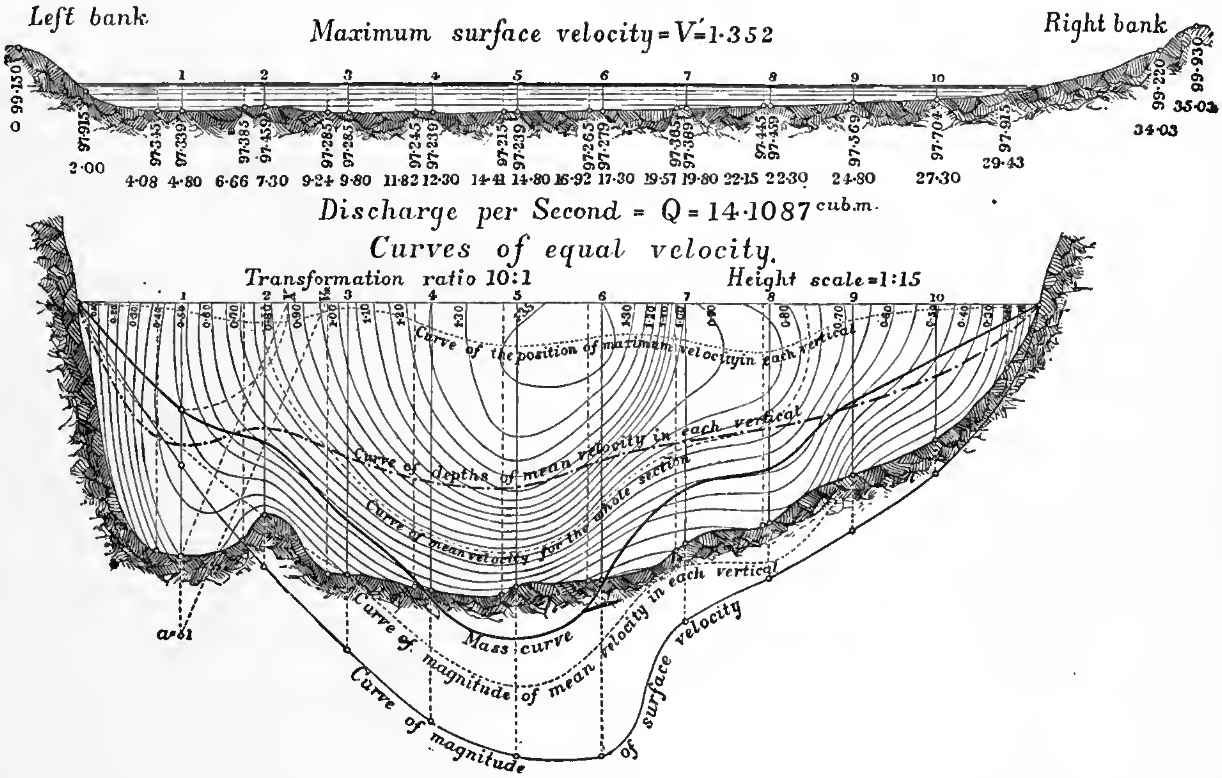

FIG. 151.

HYDRAULIC MACHINES

§ 152. Hydraulic machines may be broadly divided into two classes: (1) *Motors*, in which water descending from a higher to a lower level, or from a higher to a lower pressure, gives up energy which is available for mechanical operations; (2) *Pumps*, in which the energy of a steam engine or other motor is expended in raising water from a lower to a higher level. A few machines such as the ram and jet pump combine the functions of motor and pump. It may be noted that constructively pumps are essentially reversed motors. The reciprocating pump is a reversed pressure engine, and the centrifugal pump a reversed turbine. Hydraulic machine tools are in principle motors combined with tools, and they now form an important special class.

Water under pressure conveyed in pipes is a convenient and economical means of transmitting energy and distributing it to many scattered working points. Hence large and important hydraulic systems are adopted in which at a central station water is pumped at high pressure into distributing mains, which convey it to various points where it actuates hydraulic motors operating cranes, lifts, dock gates, and in some cases riveting and shearing machines. In this case the head driving the hydraulic machinery is artificially created, and it is the convenience of distributing power in an easily applied form to distant points which makes the system advantageous. As there is some unavoidable loss in creating an artificial head this system is most suitable for driving machines which work intermittently.

(see Power Transmission). The development of electrical methods of transmitting and distributing energy has led to the utilization of many natural waterfalls so situated as to be useless without such a means of transferring the power to points where it can be conveniently applied. In some cases, as at Niagara, the hydraulic power can only be economically developed in very large units, and it can be most conveniently subdivided and distributed by transformation into electrical energy. Partly from the development of new industries such as paper-making from wood pulp and electro-metallurgical processes, which require large amounts of cheap power, partly from the facility with which energy can now be transmitted to great distances electrically, there has been a great increase in the utilization of water-power in countries having natural waterfalls. According to the twelfth census of the United States the total amount of water-power reported as used in manufacturing establishments in that country was 1,130,431 h.p. in 1870; 1,263,343 h.p. in 1890; and 1,727,258 h.p. in 1900. The increase was 8·4% in the decade 1870–1880, 3·1% in 1880–1890, and no less than 36·7% in 1890–1900. The increase is the more striking because in this census the large amounts of hydraulic power which are transmitted electrically are not included.

XII. IMPACT AND REACTION OF WATER

§ 153. When a stream of fluid in steady motion impinges on a solid surface, it presses on the surface with a force equal and opposite to that by which the velocity and direction of motion of the fluid are changed. Generally, in problems on the impact of fluids, it is necessary to neglect the effect of friction between the fluid and the surface on which it moves.

During Impact the Velocity of the Fluid relatively to the Surface on which it impinges remains unchanged in Magnitude.—Consider a mass of fluid flowing in contact with a solid surface also in motion, the motion of both fluid and solid being estimated relatively to the earth. Then the motion of the fluid may be resolved into two parts, one a motion equal to that of the solid, and in the same direction, the other a motion relatively to the solid. The motion which the fluid has in common with the solid cannot at all be influenced by the contact. The relative component of the motion of the fluid can only be altered in direction, but not in magnitude. The fluid moving in contact with the surface can only have a relative motion parallel to the surface, while the pressure between the fluid and solid, if friction is neglected, is normal to the surface. The pressure therefore can only deviate the fluid, without altering the magnitude of the relative velocity. The unchanged common component and, combined with it, the deviated relative component give the resultant final velocity, which may differ greatly in magnitude and direction from the initial velocity.

From the principle of momentum, the impulse of any mass of fluid reaching the surface in any given time is equal to the change of momentum estimated in the same direction. The pressure between the fluid and surface, in any direction, is equal to the change of momentum in that direction of so much fluid as reaches the surface in one second. If P_a is the pressure in any direction, m the mass of fluid impinging per second, v_a the change of velocity in the direction of P_a due to impact, then

$$P_a = mv_a.$$

If v_1 (fig. 152) is the velocity and direction of motion before impact, v_2 that after impact, then v is the total change of motion due to impact. The resultant pressure of the fluid on the surface is in the direction of v, and is equal to v multiplied by the mass impinging per second. That is, putting P for the resultant pressure,

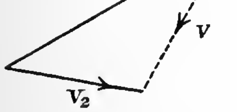

Fig. 152.

$$P = mv.$$

Let P be resolved into two components, N and T, normal and tangential to the direction of motion of the solid on which the fluid impinges. Then N is a lateral force producing a pressure on the supports of the solid, T is an effort which does work on the solid. If u is the velocity of the solid, Tu is the work done per second by the fluid in moving the solid surface.

Let Q be the volume, and GQ the weight of the fluid impinging per second, and let v_1 be the initial velocity of the fluid before striking the surface. Then $GQv_1^2/2g$ is the original kinetic energy of Q cub. ft. of fluid, and the efficiency of the stream considered as an arrangement for moving the solid surface is

$$\eta = Tu/(GQv_1^2/2g).$$

§ 154. *Jet deviated entirely in one Direction.—Geometrical Solution* (fig. 153).—Suppose a jet of water impinges on a surface ac with a velocity ab, and let it be wholly deviated in planes parallel to the figure. Also let ae be the velocity and direction of motion of the surface. Join eb; then the water moves with respect to the surface in the direction and with the velocity eb. As this relative velocity is unaltered by contact with the surface, take $cd = eb$, tangent to the surface at c, then cd is the relative motion of the water with respect to the surface at c. Take df equal and parallel to ae. Then fc (obtained by compounding the relative motion of water to surface and common velocity of water and surface) is the absolute velocity and direction

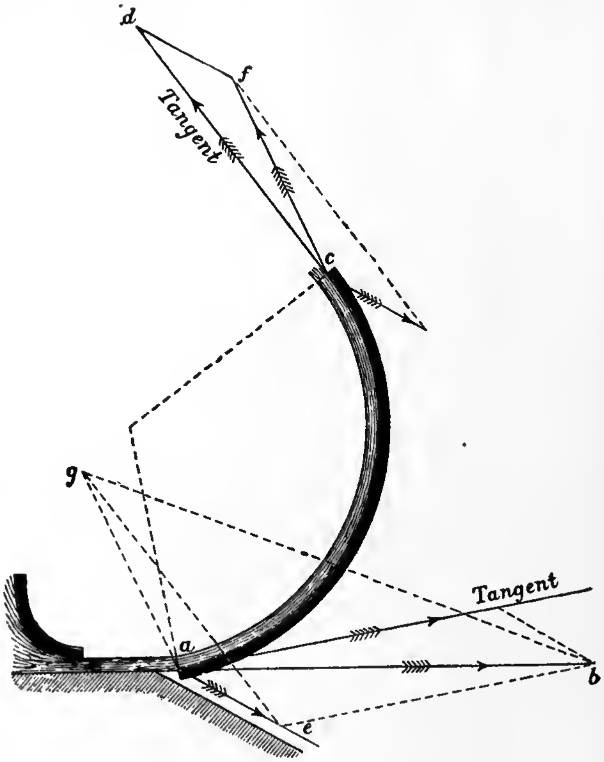

Fig. 153.

of the water leaving the surface. Take ag equal and parallel to fc. Then, since ab is the initial and ag the final velocity and direction of motion, gb is the total change of motion of the water. The resultant pressure on the plane is in the direction gb. Join eg. In the triangle gae, ae is equal and parallel to df, and ag to fc. Hence eg is equal and parallel to cd. But $cd = eb$ = relative motion of water and surface. Hence the change of motion of the water is represented in magnitude and direction by the third side of an isosceles triangle, of which the other sides are equal to the relative velocity of the water and surface, and parallel to the initial and final directions of relative motion.

Special Cases

§ 155. (1) *A Jet impinges on a plane surface at rest, in a direction normal to the plane* (fig. 154).—Let a jet whose section is ω impinge with a velocity v on a plane surface at rest, in a direction normal to the plane. The particles approach the plane, are gradually deviated, and finally flow away parallel to the plane, having then no velocity in the original direction of the jet. The quantity of water impinging per second is ωv. The pressure on the plane, which is equal to the change of momentum per second, is $P = (G/g)\omega v^2$.

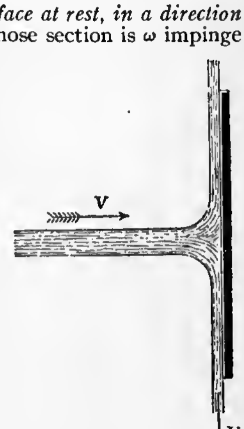

Fig. 154.

(2) *If the plane is moving in the direction of the jet with the velocity* $\pm u$, the quantity impinging per second is $\omega(v \mp u)$. The momentum of this quantity before impact is $(G/g)\omega(v \mp u)v$. After impact, the water still possesses the velocity $\pm u$ in the direction of the jet; and the momentum, in that direction, of so much water as impinges in one second, after impact, is $\pm(G/g)\omega(v \mp u)u$. The pressure on the plane, which is the change of momentum per second, is the difference of these quantities or $P = (G/g)\omega(v \mp u)^2$. This differs from the expression obtained in the previous case, in that the relative velocity of the water and plane $v \mp u$ is substituted for v. The expression may be written $P = 2 \times G \times \omega(v \mp u)^2/2g$, where the last two terms are the volume of a prism of water whose section is the area of the jet and whose length is the head due to the relative velocity. The pressure on the plane is twice the weight of that prism of water. The work done when the plane

is moving in the same direction as the jet is $Pu=(G/g)\omega(v-u)^2u$ foot-pounds per second. There issue from the jet ωv cub. ft. per second, and the energy of this quantity before impact is $(G/2g)\omega v^3$. The efficiency of the jet is therefore $\eta=2(v-u)^2u/v^3$. The value of u which makes this a maximum is found by differentiating and equating the differential coefficient to zero:—

$$d\eta/du=2(v^2-4vu+3u^2)/v^3=0;$$
$$\therefore u=v \text{ or } \tfrac{1}{3}v.$$

The former gives a minimum, the latter a maximum efficiency.

Putting $u=\frac{1}{3}v$ in the expression above,

$$\eta \text{ max.}=\tfrac{8}{27}.$$

(3) If, instead of one plane moving before the jet, a series of planes are introduced at short intervals at the same point, the quantity of water impinging on the series will be ωv instead of $\omega(v-u)$, and the whole pressure $=(G/g)\omega v(v-u)$. The work done is $(G/g)\omega vu(v-u)$. The efficiency $\eta=(G/g)\omega vu(v-u)\div(G/2g)\omega v^3=2u(v-u)/v^2$. This becomes a maximum for $d\eta/du=2(v-2u)=0$, or $u=\frac{1}{2}v$, and the $\eta=\frac{1}{2}$. This result is often used as an approximate expression for the velocity of greatest efficiency when a jet of water strikes the floats of a water wheel. The work wasted in this case is half the whole energy of the jet when the floats run at the best speed.

§ 156. (4) *Case of a Jet impinging on a Concave Cup Vane*, velocity of water v, velocity of vane in the same direction u (fig. 155), weight impinging per second $=G\omega(v-u)$.

If the cup is hemispherical, the water leaves the cup in a direction parallel to the jet. Its relative velocity is $v-u$ when approaching the cup, and $-(v-u)$ when leaving it. Hence its absolute velocity when leaving the cup is $u-(v-u)=2u-v$. The change of momentum per second $=(G/g)\omega(v-u)\ \{v-(2u-v)\}=2(G/g)\omega(v-u)^2$. Comparing this with case 2, it is seen that the pressure on a hemispherical cup is double that on a flat plane. The work done on the cup $=2(G/g)\omega\ (v-u)^2u$ foot-pounds per second. The efficiency of the jet is greatest when $v=3u$; in that case the efficiency $=\frac{16}{27}$.

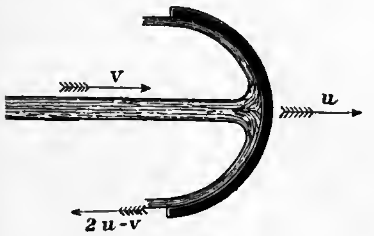

FIG. 155.

If a series of cup vanes are introduced in front of the jet, so that the quantity of water acted upon is ωv instead of $\omega(v-u)$, then the whole pressure on the chain of cups is $(G/g)\omega v\{v-(2u-v)\}=2(G/g)\omega v(v-u)$. In this case the efficiency is greatest when $v=2u$, and the maximum efficiency is unity, or all the energy of the water is expended on the cups.

§ 157. (5) *Case of a Flat Vane oblique to the Jet* (fig. 156).—This case presents some difficulty. The water spreading on the plane in all directions from the point of impact, different particles leave the plane with different absolute velocities. Let $AB=v=$ velocity of water, $AC=u=$ velocity of plane. Then, completing the parallelogram, AD represents in magnitude and direction the relative velocity of water and plane. Draw AE normal to the plane and DE parallel to the plane. Then the relative velocity AD may be regarded as consisting of two components, one AE normal, the other DE parallel to the plane. On the assumption that friction is insensible, DE is unaffected by impact, but AE is destroyed. Hence AE represents the entire change of velocity due to impact and the direction of that change. The pressure on the plane is in the direction AE, and its amount is = mass of water impinging per second $\times$ AE.

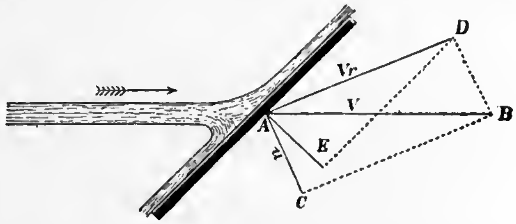

FIG. 156.

Let $DAE=\theta$, and let $AD=v_r$. Then $AE=v_r\cos\theta$; $DE=v_r\sin\theta$. If Q is the volume of water impinging on the plane per second, the change of momentum is $(G/g)Qv_r\cos\theta$. Let $AC=u=$ velocity of the plane, and let AC make the angle $CAE=\delta$ with the normal to the plane. The velocity of the plane in the direction $AE=u\cos\delta$. The work of the jet on the plane $=(G/g)Qv_r\cos\theta\ u\cos\delta$. The same problem may be thus treated algebraically (fig. 157). Let $BAF=\alpha$, and $CAF=\delta$. The velocity v of the water may be decomposed into $AF=v\cos\alpha$ normal to the plane, and $FB=v\sin\alpha$ parallel to the plane. Similarly the velocity of the plane $=u=AC=BD$ can be decomposed into $BG=FE=u\cos\delta$ normal to the plane, and $DG=u\sin\delta$ parallel to the plane. As friction is neglected, the velocity of the water parallel to the plane is unaffected by the impact, but its component $v\cos\alpha$ normal to the plane becomes after impact the same as that of the plane, that is, $u\cos\delta$. Hence the change of velocity during impact $=AE=v\cos\alpha-u\cos\delta$. The change of momentum per second, and consequently the normal

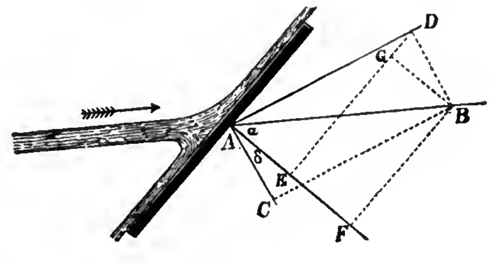

FIG. 157.

pressure on the plane is $N=(G/g)\ Q\ (v\cos\alpha-u\cos\delta)$. The pressure in the direction in which the plane is moving is $P=N\cos\delta=(G/g)Q\ (v\cos\alpha-u\cos\delta)\cos\delta$, and the work done on the plane is $Pu=(G/g)Q(v\cos\alpha-u\cos\delta)\ u\cos\delta$, which is the same expression as before, since $AE=v_r\cos\theta=v\cos\alpha-u\cos\delta$.

In one second the plane moves so that the point A (fig. 158) comes to C, or from the position shown in full lines to the position shown in dotted lines. If the plane remained stationary, a length $AB=v$ of the jet would impinge on the plane, but, since the plane moves in the same direction as the jet, only the length $HB=AB-AH$ impinges on the plane.

But $AH=AC\cos\delta/\cos\alpha=u\cos\delta/\cos\alpha$, and therefore $HB=v-u\cos\delta/\cos\alpha$. Let $\omega=$ sectional area of jet; volume impinging on plane per second $=Q=\omega(v-u\cos\delta/\cos\alpha)=\omega(v\cos\alpha-u\cos\delta)/\cos\alpha$. Inserting this in the formulae above, we get

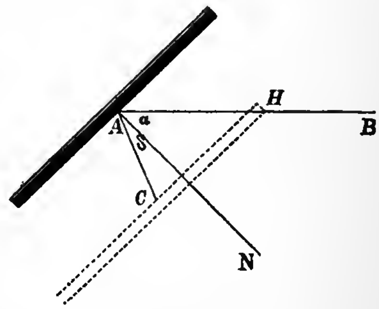

FIG. 158.

$$N=\frac{G}{g}\frac{\omega}{\cos\alpha}(v\cos\alpha-u\cos\delta)^2; \qquad (1)$$
$$P=\frac{G}{g}\frac{\omega\cos\delta}{\cos\alpha}(v\cos\alpha-u\cos\delta)^2; \qquad (2)$$
$$Pu=\frac{G}{g}\omega u\frac{\cos\delta}{\cos\alpha}(v\cos\alpha-u\cos\delta)^2. \qquad (3)$$

Three cases may be distinguished:—

(*a*) The plane is at rest. Then $u=0$, $N=(G/g)\omega v^2\cos\alpha$; and the work done on the plane and the efficiency of the jet are zero.

(*b*) The plane moves parallel to the jet. Then $\delta=\alpha$, and $Pu=(G/g)\ \omega u\cos^2\alpha(v-u)^2$, which is a maximum when $u=\frac{1}{3}v$. When $u=\frac{1}{3}v$ then Pu max. $=\frac{4}{27}(G/g)\omega v^3\cos^2\alpha$, and the efficiency $=\eta=\frac{4}{9}\cos^2\alpha$.

(*c*) The plane moves perpendicularly to the jet. Then $\delta=90°-\alpha$; $\cos\delta=\sin\alpha$; and $Pu=\frac{G}{g}\omega u\frac{\sin\alpha}{\cos\alpha}(v\cos\alpha-u\sin\alpha)^2$. This is a maximum when $u=\frac{1}{3}v\cos\alpha$.

When $u=\frac{1}{3}v\cos\alpha$, the maximum work and the efficiency are the same as in the last case.

§ 158. *Best Form of Vane to receive Water.*—When water impinges normally or obliquely on a plane, it is scattered in all directions after impact, and the work carried away by the water is then generally lost, from the impossibility of dealing afterwards with streams of water deviated in so many directions. By suitably forming the vane,

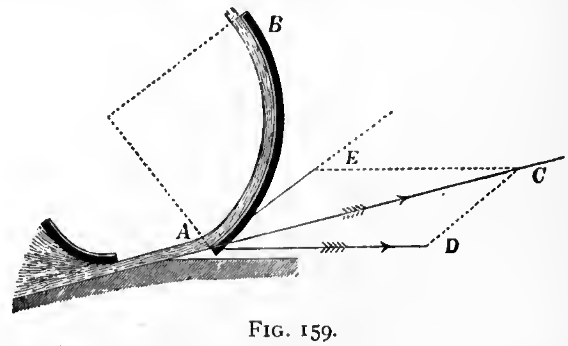

FIG. 159.

however, the water may be entirely deviated in one direction, and the loss of energy from agitation of the water is entirely avoided.

Let AB (fig. 159) be a vane, on which a jet of water impinges at the point A and in the direction AC. Take $AC=v=$ velocity of water, and let AD represent in magnitude and direction the velocity of the vane. Completing the parallelogram, DC or AE represents the direction in which the water is moving relatively to the vane. If the lip of the vane at A is tangential to AE, the water will not have its direction suddenly changed when it impinges on the vane, and will therefore have no tendency to spread laterally. On the contrary it will be so gradually deviated that it will *glide* up the vane in the direction AB. This is sometimes expressed by saying that the vane *receives the water without shock.*

§ 159. *Floats of Poncelet Water Wheels.*—Let AC (fig. 160) represent the direction of a thin horizontal stream of water having the

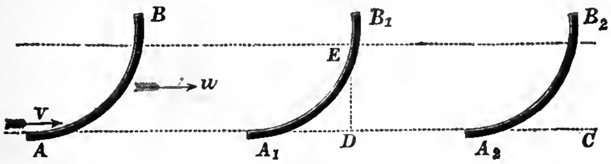

FIG. 160.

velocity v. Let AB be a curved float moving horizontally with velocity u. The relative motion of water and float is then initially horizontal, and equal to $v-u$.

In order that the float may receive the water without shock, it is necessary and sufficient that the lip of the float at A should be tangential to the direction AC of relative motion. At the end of $(v-u)/g$ seconds the float moving with the velocity u comes to the position A_1B_1, and during this time a particle of water received at A and gliding up the float with the relative velocity $v-u$, attains a height $DE=(v-u)^2/2g$. At E the water comes to relative rest. It then descends along the float, and when after $2(v-u)/g$ seconds the float has come to A_2B_2 the water will again have reached the lip at A_2 and will quit it tangentially, that is, in the direction CA_2, with a relative velocity $-(v-u)=-\sqrt{(2gDE)}$ acquired under the influence of gravity. The absolute velocity of the water leaving the float is therefore $u-(v-u)=2u-v$. If $u=\frac{1}{2}v$, the water will drop off the bucket deprived of all energy of motion. The whole of the work of the jet must therefore have been expended in driving the float. The water will have been received without shock and discharged without velocity. This is the principle of the Poncelet wheel, but in that case the floats move over an arc of a large circle; the stream of water has considerable thickness (about 8 in.); in order to get the water into and out of the wheel, it is then necessary that the lip of the float should make a small angle (about 15°) with the direction of its motion. The water quits the wheel with a little of its energy of motion remaining.

§ 160. *Pressure on a Curved Surface when the Water is deviated wholly in one Direction.*—When a jet of water impinges on a curved surface in such a direction that it is received without shock, the pressure on the surface is due to its gradual deviation from its first direction. On any portion of the area the pressure is equal and opposite to the force required to cause the deviation of so much water as rests on that surface. In common language, it is equal to the centrifugal force of that quantity of water.

Case 1. *Surface Cylindrical and Stationary.*—Let AB (fig. 161) be the surface, having its axis at O and its radius $=r$. Let the water impinge at A tangentially, and quit the surface tangentially at B. Since the surface is at rest, v is both the absolute velocity of the water and the velocity relatively to the surface, and this remains unchanged during contact with the surface, because the deviating force is at each point perpendicular to the direction of motion. The water is deviated through an angle $BCD=AOB=\phi$. Each particle of water of weight p exerts radially a centrifugal force pv^2/rg. Let the thickness of the stream $=t$ ft. Then the weight of water resting on unit of surface $=Gt$ lb; and the normal pressure per unit of surface $=n=Gtv^2/gr$. The resultant of the radial pressures uniformly distributed from A to B will be a force acting in the direction OC bisecting AOB, and its magnitude will equal that of a force of intensity $=n$, acting on the projection of AB on a plane perpendicular to the direction OC. The length of the chord $AB=2r\sin\frac{1}{2}\phi$; let b=breadth of the surface perpendicular to the plane of the figure. The resultant pressure on surface

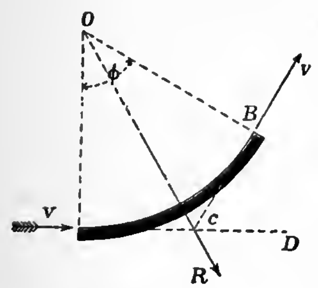

FIG. 161.

$$=R=2rb\sin\frac{\phi}{2}\times\frac{Gt}{g}\cdot\frac{v^2}{r}=2\frac{G}{g}btv^2\sin\frac{\phi}{2},$$

which is independent of the radius of curvature. It may be inferred that the resultant pressure is the same for any curved surface of the same projected area, which deviates the water through the same angle.

Case 2. *Cylindrical Surface moving in the Direction* AC *with Velocity* u.—The relative velocity $=v-u$. The final velocity BF (fig. 162) is found by combining the relative velocity $BD=v-u$ tangential to the surface with the velocity $BE=u$ of the surface. The intensity of normal pressure, as in the last case, is $(G/g)t(v-u)^2/r$. The resultant

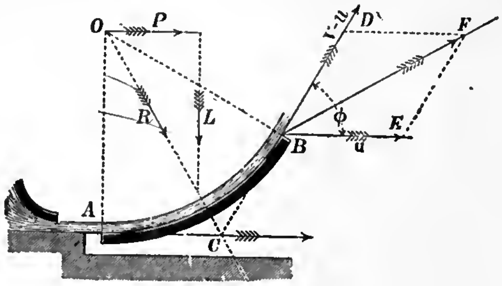

FIG. 162.

normal pressure $R=2(G/g)bt(v-u)^2\sin\frac{1}{2}\phi$. This resultant pressure may be resolved into two components P and L, one parallel and the other perpendicular to the direction of the vane's motion. The former is an effort doing work on the vane. The latter is a lateral force which does no work.

$$P=R\sin\tfrac{1}{2}\phi=(G/g)bt(v-u)^2(1-\cos\phi);$$
$$L=R\cos\tfrac{1}{2}\phi=(G/g)bt(v-u)^2\sin\phi.$$

The work done by the jet on the vane is $Pu=(G/g)btu(v-u)^2(1-\cos\phi)$, which is a maximum when $u=\frac{1}{3}v$. This result can also be obtained by considering that the work done on the plane must be equal to the energy lost by the water, when friction is neglected.

If $\phi=180°$, $\cos\phi=-1$, $1-\cos\phi=2$; then $P=2(G/g)bt(v-u)^2$, the same result as for a concave cup.

§ 161. *Position which a Movable Plane takes in Flowing Water.*—When a rectangular plane, movable about an axis parallel to one of its sides, is placed in an indefinite current of fluid, it takes a position such that the resultant of the normal pressures on the two sides of the axis passes through the axis. If, therefore, planes pivoted so that the ratio a/b (fig. 163) is varied are placed in water, and the angle they make with the direction of the stream is observed, the position of the resultant of the pressures on the plane is determined for different angular positions. Experiments of this kind have been made by Hagen. Some of his results are given in the following table:—

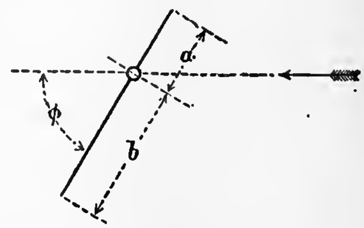

FIG. 163.

	Larger plane.	Smaller Plane.
$a/b=1\cdot0$	$\phi=\ldots$	$\phi=90°$
0·9	75°	72½°
0·8	60°	57°
0·7	48°	43°
0·6	25°	29°
0·5	13°	13°
0·4	8°	6½°
0·3	6½°	..
0·2	4°	..

§ 162. *Direct Action distinguished from Reaction* (Rankine, *Steam Engine*, § 147).

The pressure which a jet exerts on a vane can be distinguished into two parts, viz.:—

(1) The pressure arising from changing the direct component of the velocity of the water into the velocity of the vane. In fig. 153, § 154, $ab\cos bae$ is the direct component of the water's velocity, or component in the direction of motion of vane. This is changed into the velocity ae of the vane. The pressure due to direct impulse is then

$$P_1=GQ(ab\cos bae-ae)/g.$$

For a flat vane moving normally, this direct action is the only action producing pressure on the vane.

(2) The term reaction is applied to the additional action due to the direction and velocity with which the water glances off the vane. It is this which is diminished by the friction between the water and the vane. In Case 2, § 160, the direct pressure is

$$P_1=Gbt(v-u)^2/g.$$

That due to reaction is

$$P_2=-Gbt(v-u)^2\cos\phi/g.$$

If $\phi<90°$, the direct component of the water's motion is not wholly converted into the velocity of the vane, and the whole pressure due to direct impulse is not obtained. If $\phi > 90°$, $\cos\phi$ is negative and an additional pressure due to reaction is obtained.

§ 163. *Jet Propeller.*—In the case of vessels propelled by a jet of water (fig. 164), driven sternwards from orifices at the side of the vessel, the water, originally at rest outside the vessel, is drawn into the ship and caused to move with the forward velocity V of the ship. Afterwards it is projected sternwards from the jets with a velocity v relatively to the ship, or $v-\mathrm{V}$ relatively to the earth. If Ω is the total sectional area of the jets, Ωv is the quantity of water discharged per second. The momentum generated per second in a sternward direction is $(G/g)\Omega v(v-\mathrm{V})$, and this is equal to the forward acting reaction P which propels the ship.

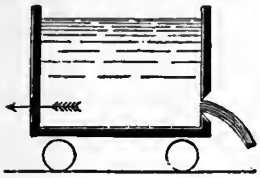

Fig. 164.

The energy carried away by the water

$$=\tfrac{1}{2}(G/g)\Omega v(v-\mathrm{V})^2. \qquad (1)$$

The useful work done on the ship

$$\mathrm{PV}=(G/g)\Omega v(v-\mathrm{V})\mathrm{V}. \qquad (2)$$

Adding (1) and (2), we get the whole work expended on the water, neglecting friction:—

$$\mathrm{W}=\tfrac{1}{2}(G/g)\Omega v(v^2-\mathrm{V}^2).$$

Hence the efficiency of the jet propeller is

$$\mathrm{PV/W}=2\mathrm{V}/(v+\mathrm{V}). \qquad (3)$$

This increases towards unity as v approaches V. In other words, the less the velocity of the jets exceeds that of the ship, and therefore the greater the area of the orifice of discharge, the greater is the efficiency of the propeller.

In the "Waterwitch" v was about twice V. Hence in this case the theoretical efficiency of the propeller, friction neglected, was about $\frac{2}{3}$.

§ 164. *Pressure of a Steady Stream in a Uniform Pipe on a Plane normal to the Direction of Motion.*—Let CD (fig. 165) be a plane

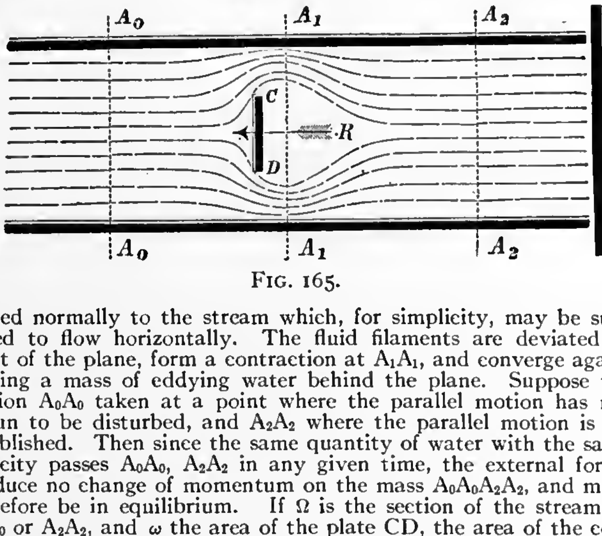

Fig. 165.

placed normally to the stream which, for simplicity, may be supposed to flow horizontally. The fluid filaments are deviated in front of the plane, form a contraction at A_1A_1, and converge again, leaving a mass of eddying water behind the plane. Suppose the section A_0A_0 taken at a point where the parallel motion has not begun to be disturbed, and A_2A_2 where the parallel motion is re-established. Then since the same quantity of water with the same velocity passes A_0A_0, A_2A_2 in any given time, the external forces produce no change of momentum on the mass $A_0A_0A_2A_2$, and must therefore be in equilibrium. If Ω is the section of the stream at A_0A_0 or A_2A_2, and ω the area of the plate CD, the area of the contracted section of the stream at A_1A_1 will be $c_c(\Omega-\omega)$, where c_c is the coefficient of contraction. Hence, if v is the velocity at A_0A_0 or A_2A_2, and v_1 the velocity at A_1A_1,

$$v\Omega=c_cv_1(\Omega-\omega);$$
$$\therefore v_1=v\Omega/c_c(\Omega-\omega). \qquad (1)$$

Let p_0, p_1, p_2 be the pressures at the three sections. Applying Bernoulli's theorem to the sections A_0A_0 and A_1A_1,

$$\frac{p_0}{G}+\frac{v^2}{2g}=\frac{p_1}{G}+\frac{v_1^2}{2g}.$$

Also, for the sections A_1A_1 and A_2A_2, allowing that the head due to the relative velocity v_1-v is lost in shock:—

$$\frac{p_1}{G}+\frac{v_1^2}{2g}=\frac{p_2}{G}+\frac{v^2}{2g}+\frac{(v_1-v)^2}{2g};$$
$$\therefore p_0-p_2=G(v_1-v)^2/2g; \qquad (2)$$

or, introducing the value in (1),

$$p_0-p_2=\frac{G}{2g}\left(\frac{\Omega}{c_c(\Omega-\omega)}-1\right)^2v^2 \qquad (3)$$

Now the external forces in the direction of motion acting on the mass $A_0A_0A_2A_2$ are the pressures $p_0\Omega$, $-p_2\Omega$ at the ends, and the reaction $-\mathrm{R}$ of the plane on the water, which is equal and opposite to the pressure of the water on the plane. As these are in equilibrium,

$$(p_0-p_2)\Omega-\mathrm{R}=0;$$
$$\therefore \mathrm{R}=G\Omega\left(\frac{\Omega}{c_c(\Omega-\omega)}-1\right)^2\frac{v^2}{2g}; \qquad (4)$$

an expression like that for the pressure of an isolated jet on an indefinitely extended plane, with the addition of the term in brackets, which depends only on the areas of the stream and the plane. For a given plane, the expression in brackets diminishes as Ω increases. If $\Omega/\omega=\rho$, the equation (4) becomes

$$\mathrm{R}=G\omega\frac{v^2}{2g}\left\{\rho\left(\frac{\rho}{c_c(\rho-1)}-1\right)^2\right\}, \qquad (4a)$$

which is of the form

$$\mathrm{R}=G\omega(v^2/2g)\mathrm{K},$$

where K depends only on the ratio of the sections of the stream and plane.

For example, let $c_c=0{\cdot}85$, a value which is probable, if we allow that the sides of the pipe act as internal borders to an orifice. Then

$$\mathrm{K}=\rho\left(1{\cdot}176\frac{\rho}{\rho-1}-1\right)^2.$$

$\rho=$	K=
1	∞
2	3·66
3	1·75
4	1·29
5	1·10
10	·94
50	2·00
100	3·50

The assumption that the coefficient of contraction c_c is constant for different values of ρ is probably only true when ρ is not very large. Further, the increase of K for large values of ρ is contrary to experience, and hence it may be inferred that the assumption that all the filaments have a common velocity v_1 at the section A_1A_1 and a common velocity v at the section A_2A_2 is not true when the stream is very much larger than the plane. Hence, in the expression

$$\mathrm{R}=\mathrm{K}G\omega v^2/2g,$$

K must be determined by experiment in each special case. For a cylindrical body putting ω for the section, c_c for the coefficient of contraction, $c_c(\Omega-\omega)$ for the area of the stream at A_1A_1,

$$v_1=v\Omega/c_c(\Omega-\omega);\ v_2=v\Omega/(\Omega-\omega);$$

or, putting $\rho=\Omega/\omega$,

$$v_1=v\rho/c_c(\rho-1),\ v_2=v\rho/(\rho-1).$$

Then

$$\mathrm{R}=\mathrm{K}_1G\omega v^2/2g,$$

where

$$\mathrm{K}_1=\rho\left\{\left(\frac{\rho}{\rho-1}\right)^2\left(\frac{1}{c_c}-1\right)^2+\left(\frac{\rho}{\rho-1}-1\right)^2\right\}.$$

Taking $c_c=0{\cdot}85$ and $\rho=4$, $\mathrm{K}_1=0{\cdot}467$, a value less than before. Hence there is less pressure on the cylinder than on the thin plane.

§ 165. *Distribution of Pressure on a Surface on which a Jet impinges normally.*—The principle of momentum gives readily enough the total or resultant pressure of a jet impinging on a plane surface, but in some cases it is useful to know the distribution of the pressure. The problem in the case in which the plane is struck normally, and the jet spreads in all directions, is one of great complexity, but even in that case the maximum intensity of the pressure is easily assigned. Each layer of water flowing from an orifice is gradually deviated (fig. 166) by contact with the surface, and during deviation exercises a centrifugal pressure towards the axis of the jet. The force exerted by each small mass of water is normal to its path and inversely as the radius of curvature of the path. Hence the greatest pressure on the plane must be at the axis of the jet, and the pressure must decrease from the axis outwards, in some such way as is shown by the curve of pressure in fig. 167, the branches of the curve being probably asymptotic to the plane.

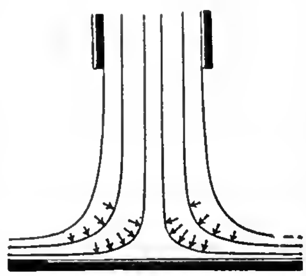

Fig. 166.

For simplicity suppose the jet is a vertical one. Let h_1 (fig. 167) be the depth of the orifice from the free surface, and v_1 the velocity of discharge. Then, if ω is the area of the orifice, the quantity of water impinging on the plane is obviously

$$Q=\omega v_1=\omega\sqrt{(2gh_1)};$$

that is, supposing the orifice rounded, and neglecting the coefficient of discharge.

The velocity with which the fluid reaches the plane is, however, greater than this, and may reach the value

$$v=\sqrt{(2gh)};$$

where h is the depth of the plane below the free surface. The external layers of fluid subjected throughout, after leaving the orifice, to the atmospheric pressure will attain the velocity v, and will flow away with this velocity unchanged except by friction. The layers towards the interior of the jet, being subjected to a pressure greater than atmospheric pressure, will attain a less velocity, and so much less as they are nearer the centre of the jet. But the pressure can in no case exceed the pressure $v^2/2g$ or h measured in feet of water, or the direction of motion of the water would be reversed, and there would be reflux. Hence the maximum intensity of the pressure

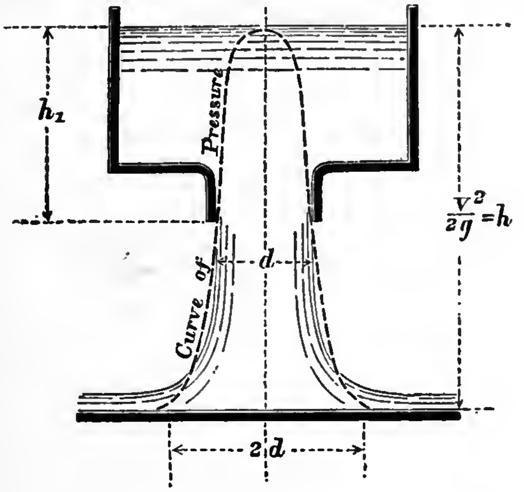

FIG. 167.

of the jet on the plane is h ft. of water. If the pressure curve is drawn with pressures represented by feet of water, it will touch the free water surface at the centre of the jet.

Suppose the pressure curve rotated so as to form a solid of revolution. The weight of water contained in that solid is the total pressure of the jet on the surface, which has already been determined. Let V = volume of this solid, then GV is its weight in pounds. Consequently

$$GV = (G/g)\omega v_1 v;$$
$$V = 2\omega\sqrt{(hh_1)}.$$

We have already, therefore, two conditions to be satisfied by the pressure curve.

Some very interesting experiments on the distribution of pressure on a surface struck by a jet have been made by J. S. Beresford (*Prof. Papers on Indian Engineering*, No. cccxxii.), with a view to afford information as to the forces acting on the aprons of weirs. Cylindrical jets ½ in. to 2 in. diameter, issuing from a vessel in which the water level was constant, were allowed to fall vertically on a brass plate 9 in. in diameter. A small hole in the brass plate communicated by a flexible tube with a vertical pressure column. Arrangements were made by which this aperture could be moved $\frac{1}{20}$ in. at a time across the area struck by the jet. The height of the pressure column, for each position of the aperture, gave the pressure at that point of the area struck by the jet. When the aperture was

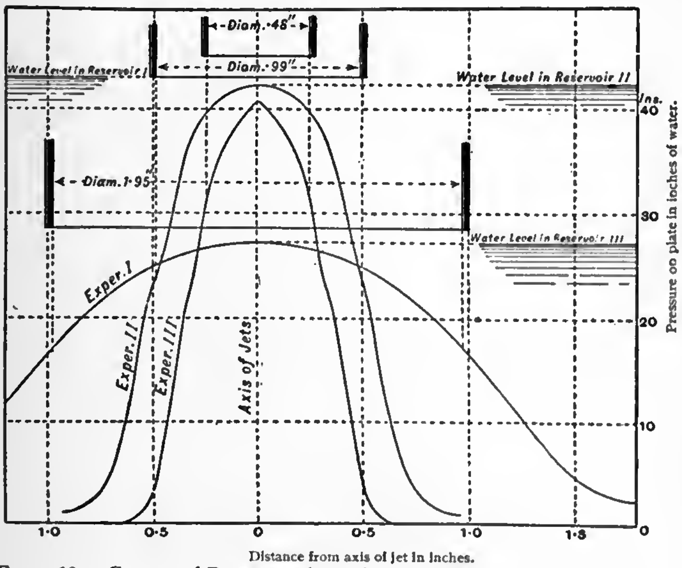

FIG. 168.—Curves of Pressure of Jets impinging normally on a Plane.

exactly in the axis of the jet, the pressure column was very nearly level with the free surface in the reservoir supplying the jet; that is, the pressure was very nearly $v^2/2g$. As the aperture moved away from the axis of the jet, the pressure diminished, and it became insensibly small at a distance from the axis of the jet about equal to the diameter of the jet. Hence, roughly, the pressure due to the jet extends over an area about four times the area of section of the jet.

Fig. 168 shows the pressure curves obtained in three experiments with three jets of the sizes shown, and with the free surface level in the reservoir at the heights marked.

As the general form of the pressure curve has been already indicated, it may be assumed that its equation is of the form

$$y = ab^{-x^2}. \qquad (1)$$

But it has already been shown that for $x=0$, $y=h$, hence $a=h$. To determine the remaining constant, the other condition may be used, that the solid formed by rotating the pressure curve represents the total pressure on the plane. The volume of the solid is

$$V = \int_0^\infty 2\pi xy dx$$
$$= 2\pi h \int_0^\infty b^{-x^2} x dx$$
$$= (\pi h/\log_e b)\Big[-b^{-x^2}\Big]_0^\infty$$
$$= \pi h/\log_e b.$$

Using the condition already stated,

$$2\omega\sqrt{(hh_1)} = \pi h/\log_e b,$$
$$\log_e b = (\pi/2\omega)\sqrt{(h/h_1)}.$$

Putting the value of b in (2) in eq. (1), and also r for the radius of the jet at the orifice, so that $\omega = \pi r^2$, the equation to the pressure curve is

$$y = h\epsilon^{-\frac{1}{2}\sqrt{\frac{h}{h_1}\frac{x^2}{r^2}}}.$$

§ 166. *Resistance of a Plane moving through a Fluid, or Pressure of a Current on a Plane.*—When a thin plate moves through the air, or through an indefinitely large mass of still water, in a direction normal to its surface, there is an excess of pressure on the anterior face and a diminution of pressure on the posterior face. Let v be the relative velocity of the plate and fluid, Ω the area of the plate, G the density of the fluid, h the height due to the velocity, then the total resistance is expressed by the equation

$$R = fG\Omega\, v^2/2g \text{ pounds} = fG\Omega h;$$

where f is a coefficient having about the value 1·3 for a plate moving in still fluid, and 1·8 for a current impinging on a fixed plane, whether the fluid is air or water. The difference in the value of the coefficient in the two cases is perhaps due to errors of experiment. There is a similar resistance to motion in the case of all bodies of "*unfair*" form, that is, in which the surfaces over which the water slides are not of gradual and continuous curvature.

The stress between the fluid and plate arises chiefly in this way.

The streams of fluid deviated in front of the plate, supposed for definiteness to be moving through the fluid, receive from it forward momentum. Portions of this forward moving water are thrown off laterally at the edges of the plate, and diffused through the surrounding fluid, instead of falling to their original position behind the plate. Other portions of comparatively still water are dragged into motion to fill the space left behind the plate; and there is thus a pressure less than hydrostatic pressure at the back of the plate. The whole resistance to the motion of the plate is the sum of the excess of pressure in front and deficiency of pressure behind. This resistance is independent of any friction or viscosity in the fluid, and is due simply to its inertia resisting a sudden change of direction at the edge of the plate.

Experiments made by a whirling machine, in which the plate is fixed on a long arm and moved circularly, gave the following values of the coefficient f. The method is not free from objection, as the centrifugal force causes a flow outwards across the plate.

Approximate Area of Plate in sq. ft.	Values of f.		
	Borda.	Hutton.	Thibault.
0·13	1·39	1·24	..
0·25	1·49	1·43	1·525
0·63	1·64	..	..
1·11	..	..	1·784

There is a steady increase of resistance with the size of the plate, in part or wholly due to centrifugal action.

P. L. G. Dubuat (1734–1809) made experiments on a plane 1 ft. square, moved in a straight line in water at 3 to $6\frac{1}{2}$ ft. per second. Calling m the coefficient of excess of pressure in front, and n the coefficient of deficiency of pressure behind, so that $f=m+n$, he found the following values:—

$$m=1;\ n=0·433;\ f=1·433.$$

The pressures were measured by pressure columns. Experiments by A. J. Morin (1795–1880), G. Piobert (1793–1871) and I. Didion (1798–1878) on plates of 0·3 to 2·7 sq. ft. area, drawn vertically through water, gave $f=2·18$; but the experiments were made in a reservoir of comparatively small depth. For similar plates moved through air they found $f=1·36$, a result more in accordance with those which precede.

For a fixed plane in a moving current of water E. Mariotte found $f=1·25$. Dubuat, in experiments in a current of water like those mentioned above, obtained the values $m=1·186$; $n=0·670$; $f=1·856$. Thibault exposed to wind pressure planes of 1·17 and 2·5 sq. ft. area, and found f to vary from 1·568 to 2·125, the mean value being $f=1·834$, a result agreeing well with Dubuat.

§ 167. *Stanton's Experiments on the Pressure of Air on Surfaces.*—At the National Physical Laboratory, London, T. E. Stanton carried out a series of experiments on the distribution of pressure on surfaces in a current of air passing through an air trunk. These were on a small scale but with exceptionally accurate means of measurement. These experiments differ from those already given in that the plane is small relatively to the cross section of the current (*Proc. Inst. Civ. Eng.* clvi., 1904). Fig. 169 shows the distribution of pressure on a square plate. ab is the plate in vertical section. acb the distribution of pressure on the windward and adb that on the leeward side of the central section. Similarly aeb is the distribution of pressure on the windward and afb on the leeward side of a diagonal section. The intensity of pressure at the centre of the plate on the windward side was in all cases $p=Gv^2/2g$ lb per sq. ft., where G is the weight of a cubic foot of air and v the velocity of the current in ft. per sec. On the leeward side the negative pressure is uniform except near the edges, and its value depends on the form of the plate. For a circular plate the pressure on the leeward side was 0·48 $Gv^2/2g$ and for a rectangular plate 0·66 $Gv^2/2g$. For circular or square plates the resultant pressure on the plate was $P=0·00126\ v^2$ lb per sq. ft. where v is the velocity of the current in ft. per sec. On a long narrow rectangular plate the resultant pressure was nearly 60% greater than on a circular plate. In later tests on larger planes in free air, Stanton found resistances 18% greater than those observed with small planes in the air trunk.

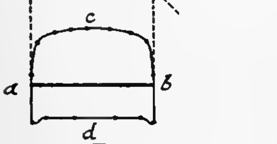

FIG. 169.

§ 168. *Case when the Direction of Motion is oblique to the Plane.*—The determination of the pressure between a fluid and surface in this case is of importance in many practical questions, for instance, in assigning the load due to wind pressure on sloping and curved roofs, and experiments have been made by Hutton, Vince, and Thibault on planes moved circularly through air and water on a whirling machine.

Let AB (fig. 170) be a plane moving in the direction R making an angle ϕ with the plane. The resultant pressure between the fluid and the plane will be a normal pressure N. The component R of this normal pressure is the resistance to the motion of the plane and the other component L is a lateral force resisted by the guides which support the plane. Obviously

$$R=N\sin\phi;$$
$$L=N\cos\phi.$$

In the case of wind pressure on a sloping roof surface, R is the horizontal and L the vertical component of the normal pressure.

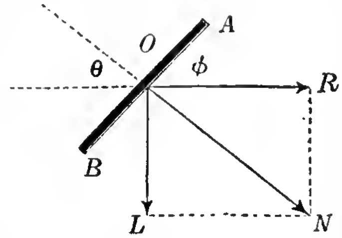

FIG. 170.

In experiments with the whirling machine it is the resistance to motion, R, which is directly measured. Let P be the pressure on a plane moved normally through a fluid. Then, for the same plane inclined at an angle ϕ to its direction of motion, the resistance was found by Hutton to be

$$R=P(\sin\phi)^{1·842\cos\phi}.$$

A simpler and more convenient expression given by Colonel Duchemin is

$$R=2P\sin^2\phi/(1+\sin^2\phi).$$

Consequently, the total pressure between the fluid and plane is

$$N=2P\sin\phi/(1+\sin^2\phi)=2P/(\operatorname{cosec}\phi+\sin\phi),$$

and the lateral force is

$$L=2P\sin\phi\cos\phi/(1+\sin^2\phi).$$

In 1872 some experiments were made for the Aeronautical Society on the pressure of air on oblique planes. These plates, of 1 to 2 ft. square, were balanced by ingenious mechanism designed by F. H. Wenham and Spencer Browning, in such a manner that both the pressure in the direction of the air current and the lateral force were separately measured. These planes were placed opposite a blast from a fan issuing from a wooden pipe 18 in. square. The pressure of the blast varied from $\frac{6}{10}$ to 1 in. of water pressure. The following are the results given in pounds per square foot of the plane, and a comparison of the experimental results with the pressures given by Duchemin's rule. These last values are obtained by taking $P=3·31$, the observed pressure on a normal surface:—

Angle between Plane and Direction of Blast	15°	20°	60°	90°
Horizontal pressure R	0·4	0·61	2·73	3·31
Lateral pressure L	1·6	1·96	1·26	..
Normal pressure $\sqrt{L^2+R^2}$	1·65	2·05	3·01	3·31
Normal pressure by Duchemin's rule	1·605	2·027	3·276	3·31

WATER MOTORS

In every system of machinery deriving energy from a natural water-fall there exist the following parts:—

1. A supply channel or head race, leading the water from the highest accessible level to the site of the machine. This may be an open channel of earth, masonry or wood, laid at as small a slope as is consistent with the delivery of the necessary supply of water, or it may be a closed cast or wrought-iron pipe, laid at the natural slope of the ground, and about 3 ft. below the surface. In some cases part of the head race is an open channel, part a closed pipe. The channel often starts from a small storage reservoir, constructed near the stream supplying the water motor, in which the water accumulates when the motor is not working. There are sluices or penstocks by which the supply can be cut off when necessary.

2. Leading from the motor there is a tail race, culvert, or discharge pipe delivering the water after it has done its work at the lowest convenient level.

3. A waste channel, weir, or bye-wash is placed at the origin of the head race, by which surplus water, in floods, escapes.

4. The motor itself, of one of the kinds to be described presently, which either overcomes a useful resistance directly, as in the case of a ram acting on a lift or crane chain, or indirectly by actuating transmissive machinery, as when a turbine drives the shafting, belting and gearing of a mill. With the motor is usually combined regulating machinery for adjusting the power and speed to the work done. This may be controlled in some cases by automatic governing machinery.

§ 169. *Water Motors with Artificial Sources of Energy.*—The great convenience and simplicity of water motors has led to their adoption in certain cases, where no natural source of water power is available. In these cases, an artificial source of water power is created by using a steam-engine to pump water to a reservoir at a great elevation, or to pump water into a closed reservoir in which there is great pressure. The water flowing from the reservoir through hydraulic engines gives back the energy expended, less so much as has been wasted by friction. Such arrangements are most useful where a continuously acting steam engine stores up energy by pumping the water, while the work done by the hydraulic engines is done intermittently.

§ 170. *Energy of a Water-fall.*—Let H_t be the total fall of level from the point where the water is taken from a natural stream to the point where it is discharged into it again. Of this total fall a portion, which can be estimated independently, is expended in overcoming the resistances of the head and tail races or the supply and discharge pipes. Let this portion of head wasted be $\mathfrak{h}_r$. Then the available head to work the motor is $H = H_t - \mathfrak{h}_r$. It is this available head which should be used in all calculations of the proportions of the motor. Let Q be the supply of water per second. Then GQH foot-pounds per second is the gross available work of the fall. The power of the fall may be utilized in three ways. (*a*) The GQ pounds of water may be placed on a machine at the highest level, and descending in contact with it a distance of H ft., the work done will be (neglecting losses from friction or leakage) GQH foot-pounds per second. (*b*) Or the water may descend in a closed pipe from the higher to the lower level, in which case, with the same reservation as before, the pressure at the foot of the pipe will be $p = GH$ pounds per square foot. If the water with this pressure acts on a movable piston like that of a steam engine, it will drive the piston so that the volume described is Q cubic feet per second. Then the work done will be $pQ = GHQ$ foot-pounds per second as before. (*c*) Or lastly, the water may be allowed to acquire the velocity $v = \sqrt{2gH}$ by its descent. The kinetic energy of Q cubic feet will then be $\frac{1}{2}GQv^2/g = GQH$, and if the water is allowed to impinge on surfaces suitably curved which bring it finally to rest, it will impart to these the same energy as in the previous cases. Motors which receive energy mainly in the three ways described in (*a*), (*b*), (*c*) may be termed gravity, pressure and inertia motors respectively. Generally, if Q ft. per second of water act by weight through a distance h_1, at a pressure p due to h_2 ft. of fall, and with a velocity v due to h_3 ft. of fall, so that $h_1 + h_2 + h_3 = H$, then, apart from energy wasted by friction or leakage or imperfection of the machine, the work done will be

$$GQh_1 + pQ + (G/g)Q(v^2/2g) = GQH \text{ foot pounds},$$

the same as if the water acted simply by its weight while descending H ft.

§ 171. *Site for Water Motor.*—Wherever a stream flows from a higher to a lower level it is possible to erect a water motor. The amount of power obtainable depends on the available head and the supply of water. In choosing a site the engineer will select a portion of the stream where there is an abrupt natural fall, or at least a considerable slope of the bed. He will have regard to the facility of constructing the channels which are to convey the water, and will take advantage of any bend in the river which enables him to shorten them. He will have accurate measurements made of the quantity of water flowing in the stream, and he will endeavour to ascertain the average quantity available throughout the year, the minimum quantity in dry seasons, and the maximum for which bye-wash channels must be provided. In many cases the natural fall can be increased by a dam or weir thrown across the stream. The engineer will also examine to what extent the head will vary in different seasons, and whether it is necessary to sacrifice part of the fall and give a steep slope to the tail race to prevent the motor being drowned by backwater in floods. Streams fed from lakes which form natural reservoirs or fed from glaciers are less variable than streams depending directly on rainfall, and are therefore advantageous for water-power purposes.

§ 172. *Water Power at Holyoke, U.S.A.*—About 85 m. from the mouth of the Connecticut river there was a fall of about 60 ft. in a short distance, forming what were called the Grand Rapids, below which the river turned sharply, forming a kind of peninsula on which the city of Holyoke is built. In 1845 the magnitude of the water-power available attracted attention, and it was decided to build a dam across the river. The ordinary flow of the river is 6000 cub. ft. per sec., giving a gross power of 30,000 h.p. In dry seasons the power is 20,000 h.p., or occasionally less. From above the dam a system of canals takes the water to mills on three levels. The first canal starts with a width of 140 ft. and depth of 22 ft., and supplies the highest range of mills. A second canal takes the water which has driven turbines in the highest mills and supplies it to a second series of mills. There is a third canal on a still lower level supplying the lowest mills. The water then finds its way back to the river. With the grant of a mill site is also leased the right to use the water-power. A mill-power is defined as 38 cub. ft. of water per sec. during 16 hours per day on a fall of 20 ft. This gives about 60 h.p. effective. The charge for the power water is at the rate of 20s. per h.p. per annum.

§ 173. *Action of Water in a Water Motor.*—Water motors may be divided into water-pressure engines, water-wheels and turbines.

Water-pressure engines are machines with a cylinder and piston or ram, in principle identical with the corresponding part of a steam-engine. The water is alternately admitted to and discharged from the cylinder, causing a reciprocating action of the piston or plunger. It is admitted at a high pressure and discharged at a low one, and consequently work is done on the piston. The water in these machines never acquires a high velocity, and for the most part the kinetic energy of the water is wasted. The useful work is due to the difference of the pressure of admission and discharge, whether that pressure is due to the weight of a column of water of more or less considerable height, or is artificially produced in ways to be described presently.

Water-wheels are large vertical wheels driven by water falling from a higher to a lower level. In most water-wheels, the water acts directly by its weight loading one side of the wheel and so causing rotation. But in all water-wheels a portion, and in some a considerable portion, of the work due to gravity is first employed to generate kinetic energy in the water; during its action on the water-wheel the velocity of the water diminishes, and the wheel is therefore in part driven by the impulse due to the change of the water's momentum. Water-wheels are therefore motors on which the water acts, partly by weight, partly by impulse.

Turbines are wheels, generally of small size compared with water wheels, driven chiefly by the impulse of the water. Before entering the moving part of the turbine, the water is allowed to acquire a considerable velocity; during its action on the turbine this velocity is diminished, and the impulse due to the change of momentum drives the turbine.

In designing or selecting a water motor it is not sufficient to consider only its efficiency in normal conditions of working. It is generally quite as important to know how it will act with a scanty water supply or a diminished head. The greatest difference in water motors is in their adaptability to varying conditions of working.

Water-pressure Engines.

§ 174. In these the water acts by pressure either due to the height of the column in a supply pipe descending from a high-level reservoir, or created by pumping. Pressure engines were first used in mine-pumping on waterfalls of greater height than could at that time be utilized by water wheels. Usually they were single acting, the water-pressure lifting the heavy pump rods which then made the return or pumping stroke by their own weight. To avoid losses by fluid friction and shock the velocity of the water in the pipes and passages was restricted to from 3 to 10 ft. per second, and the mean speed of plunger to 1 ft. per second. The stroke was long and the number of strokes 3 to 6 per minute. The pumping lift being constant, such engines worked practically always at full load, and the efficiency was high, about 84%. But they were cumbrous machines. They are described in Weisbach's *Mechanics of Engineering.*

The convenience of distributing energy from a central station to scattered working-points by pressure water conveyed in pipes—a system invented by Lord Armstrong—has already been mentioned. This system has led to the development of a great variety of hydraulic pressure engines of very various types. The cost of pumping the pressure water to some extent restricts its use to intermittent operations, such as working lifts and cranes, punching, shearing and riveting machines, forging and flanging presses. To keep down the cost of the distributing mains very high pressures are adopted, generally 700 ℔ per sq. in. or 1600 ft. of head or more.

In a large number of hydraulic machines worked by water at high pressure, especially lifting machines, the motor consists of a direct, single acting ram and cylinder. In a few cases double-acting pistons and cylinders are used; but they involve a water-tight packing of the piston not easily accessible. In some cases pressure engines are used to obtain rotative movement, and then two double-acting cylinders or three single-acting cylinders are used, driving a crank shaft. Some double-acting cylinders have a piston rod half the area of the piston. The pressure water acts continuously on the annular area in front of the piston. During the forward stroke the pressure on the front of the piston balances half the pressure on the back. During the return stroke the pressure on the front is unopposed. The water in front of the piston is not exhausted, but returns to the supply pipe. As the frictional losses in a fluid are independent of the pressure, and the work done increases directly as the pressure, the percentage loss decreases for given velocities of flow as the pressure increases. Hence for high-pressure machines somewhat greater velocities are permitted in the passages than for low-pressure machines. In supply mains the velocity is from 3 to 6 ft. per second, in valve passages 5 to 10 ft. per second, or in extreme cases 20 ft. per second, where there is less object in economizing energy. As the water is incompressible, slide valves must have neither lap nor lead, and piston valves are preferable to ordinary slide valves. To prevent injurious compression from exhaust valves closing too soon in rotative engines with a fixed stroke, small self-acting relief valves are fitted to the cylinder ends, opening outwards against the pressure into the valve chest. Imprisoned water can then escape without over-straining the machines.

In direct single-acting lift machines, in which the stroke is fixed, and in rotative machines at constant speed it is obvious that the cylinder must be filled at each stroke irrespective of the amount of work to be done. The same amount of water is used whether much or little work is done, or whether great or small weights are lifted. Hence while pressure engines are very efficient at full load, their efficiency decreases as the load decreases. Various arrangements have been adopted to diminish this defect in engines working with a variable load. In lifting machinery there is sometimes a double ram, a hollow ram enclosing a solid ram. By simple arrangements the solid ram only is used for small loads, but for large loads the hollow ram is locked to the solid ram, and the two act as a ram of larger area. In rotative engines the case is more difficult. In Hastie's and Rigg's engines the stroke is automatically varied with the load, increasing when the load is large and decreasing when it is small. But such engines are complicated and have not achieved much success. Where pressure engines are used simplicity is generally a first consideration, and economy is of less importance.

§ 175. *Efficiency of Pressure Engines.*—It is hardly possible to form a theoretical expression for the efficiency of pressure engines, but some general considerations are useful. Consider the case of a long stroke hydraulic ram, which has a fairly constant velocity v during the stroke, and valves which are fairly wide open during most of the stroke. Let r be the ratio of area of ram to area of valve passage, a ratio which may vary in ordinary cases from 4 to 12. Then the loss in shock of the water entering the cylinder will be $(r-1)^2v^2/2g$ in ft. of head. The friction in the supply pipe is also proportional to v^2. The energy carried away in exhaust will be proportional to v^2. Hence the total hydraulic losses may be taken to be approximately $\zeta v^2/2g$ ft., where ζ is a coefficient depending on the proportions of the machine. Let f be the friction of the ram packing and mechanism reckoned in ℔ per sq. ft. of ram area. Then if the supply-pipe pressure driving the machine is p ℔ per sq. ft., the effective working pressure will be

$$p - G\zeta v^2/2g - f \text{ ℔ per sq. ft.}$$

Let A be the area of the ram in sq. ft., v its velocity in ft. per sec. The useful work done will be

$$(p - G\zeta v^2/2g - f)Av \text{ ft. ℔ per sec.,}$$

and the efficiency of the machine will be

$$\eta = (p - G\zeta v^2/2g - f)/p.$$

This shows that the efficiency increases with the pressure p, and diminishes with the speed v, other things being the same. If in regulating the engine for varying load the pressure is throttled, part of the available head is destroyed at the throttle valve, and p in the bracket above is reduced. Direct-acting hydraulic lifts, without intermediate gearing, may have an efficiency of 95 % during the working stroke. If a hydraulic jigger is used with ropes and sheaves to change the speed of the ram to the speed of the lift, the efficiency may be only 50 %. E. B. Ellington has given the efficiency of lifts with hydraulic balance at 85 % during the working stroke. Large pressure engines have an efficiency of 85 %, but small rotative engines probably not more than 50 % and that only when fully loaded.

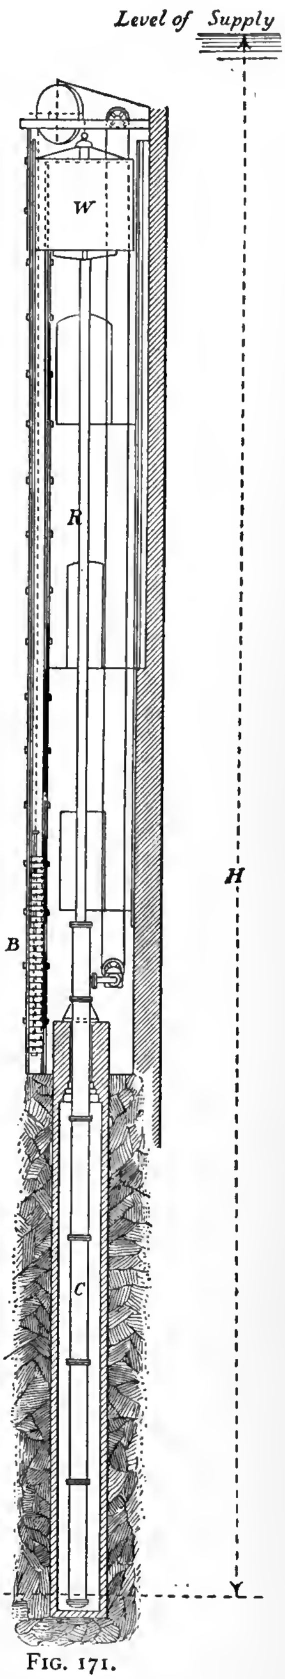

FIG. 171.

§ 176. *Direct-Acting Hydraulic Lift* (fig. 171).—This is the simplest of all kinds of hydraulic motor. A cage W is lifted directly by water pressure acting in a cylinder C, the length of which is a little greater than the lift. A ram or plunger R of the same length is attached to the cage. The water-pressure admitted by a cock to the cylinder forces up the ram, and when the supply valve is closed and the discharge valve opened, the ram descends. In this case the ram is 9 in. diameter, with a stroke of 49 ft. It consists of lengths of wrought-iron pipe screwed together perfectly water-tight, the lower end being closed by a cast-iron plug. The ram works in a cylinder 11 in. diameter of 9 ft. lengths of flanged cast-iron pipe. The ram passes water-tight through the cylinder cover, which is provided with double hat leathers to prevent leakage outwards or inwards. As the weight of the ram and cage is much more than sufficient to cause a descent of the cage, part of the weight is balanced. A chain attached to the cage passes over a pulley at the top of the lift, and carries at its free end a balance weight B, working in T iron guides. Water is admitted to the cylinder from a 4-in. supply pipe through a two-way slide, worked by a rack, spindle and endless rope. The lift works under 73 ft. of head, and lifts 1350 ℔ at 2 ft. per second. The efficiency is from 75 to 80 %.

The principal prejudicial resistance to the motion of a ram of this kind is the friction of the cup leathers, which make the joint between the cylinder and ram. Some experiments by John Hick give for the friction of these leathers the following formula. Let F = the total friction in pounds;

d = diameter of ram in ft.; p = water-pressure in pounds per sq. ft.; k a coefficient.

$F = k\,p\,d$

$k = 0{\cdot}00393$ if the leathers are new or badly lubricated;

$= 0{\cdot}00262$ if the leathers are in good condition and well lubricated.

Since the total pressure on the ram is $P = \frac{1}{4}\pi d^2 p$, the fraction of the total pressure expended in overcoming the friction of the leathers is $F/P = {\cdot}005/d$ to ${\cdot}0033/d$, d being in feet.

Let H be the height of the pressure column measured from the free surface of the supply reservoir to the bottom of the ram in its lowest position, H_b the height from the discharge reservoir to the same point, h the height of the ram above its lowest point at any moment, S the length of stroke, Ω the area of the ram, W the weight of cage, R the weight of ram, B the weight of balance weight, w the weight of balance chain per foot run, F the friction of the cup leather and slides. Then, neglecting fluid friction, if the ram is rising the accelerating force is

$$P_1 = G(H-h)\Omega - R - W + B - w(S-h) + wh - F,$$

and if the ram is descending

$$P_2 = -G(H_b-h)\Omega + W + R - B + w(S-h) - wh - F.$$

If $w = \frac{1}{2}\,G\Omega$, P_1 and P_2 are constant throughout the stroke; and the moving force in ascending and descending is the same, if

$$B = W + R + wS - G\Omega(H+H_b)/2.$$

Using the values just found for w and B,

$$P_1 = P_2 = \tfrac{1}{2}G\Omega(H-H_b) - F.$$

Let $W+R+wS+B = U$, and let P be the constant accelerating force acting on the system, then the acceleration is $(P/U)g$. The velocity at the end of the stroke is (assuming the friction to be constant)

$$v = \sqrt{(2PgS/U)};$$

and the mean velocity of ascent is $\frac{1}{2}v$.

§ 177. *Armstrong's Hydraulic Jigger.*—This is simply a single-acting hydraulic cylinder and ram, provided with sheaves so as to give motion to a wire rope or chain. It is used in various forms of lift and crane. Fig. 172 shows the arrangement. A hydraulic ram or plunger B works in a stationary cylinder A. Ram and cylinder carry sets of sheaves over which passes a chain or rope, fixed at one end to the cylinder, and at the other connected over guide pulleys to a lift or crane. For each pair of pulleys, one on the cylinder and one on the ram, the movement of the free end of the rope is doubled compared with that of the ram. With three pairs of pulleys the free end of the rope has a movement equal to six times the stroke of the ram, the force exerted being in the inverse proportion.

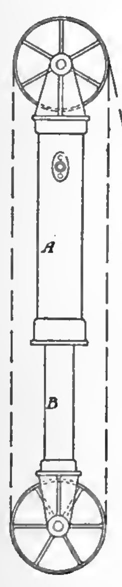

FIG. 172.

§ 178. *Rotative Hydraulic Engines.*—Valve-gear mechanism similar in principle to that of steam engines can be applied to actuate the admission and discharge valves, and the pressure engine is then converted into a continuously-acting motor.

Let H be the available fall to work the engine after deducting the loss of head in the supply and discharge pipes, Q the supply of water in cubic feet per second, and η the efficiency of the engine. Then the horse-power of the engine is

$$\text{H.P.} = \eta GQH/550.$$

The efficiency of large slow-moving pressure engines is $\eta = {\cdot}66$ to ${\cdot}8$. In small motors of this kind probably η is not greater than ${\cdot}5$. Let v be the mean velocity of the piston, then its diameter d is given by the relation

$$Q = \pi d^2 v/4 \text{ in double-acting engines,}$$
$$= \pi d^2 v/8 \text{ in single-acting engines.}$$

If there are n cylinders put Q/n for Q in these equations.

Small rotative pressure engines form extremely convenient motors for hoists, capstans or winches, and for driving small machinery. The single-acting engine has the advantage that the pressure of the piston on the crank pin is always in one direction; there is then no knocking as the dead centres are passed. Generally three single-acting cylinders are used, so that the engine will readily start in all positions, and the driving effort on the crank pin is very uniform.

Brotherhood Hydraulic Engine.—Three cylinders at angles of 120° with each other are formed in one casting with the frame. The plungers are hollow trunks, and the connecting rods abut in cylindrical recesses in them and are connected to a common crank pin. A circular valve disk with concentric segmental ports revolves at the same rate as the crank over ports in the valve face common to the three cylinders. Each cylinder is always in communication with either an admission or exhaust port. The blank parts of the circular valve close the admission and exhaust ports alternately. The fixed valve face is of lignum vitae in a metal recess, and the revolving valve of gun-metal. In the case of a small capstan engine the cylinders are $3\frac{1}{2}$ in. diameter and 3 in. stroke. At 40 revs. per minute, the piston speed is 31 ft. per minute. The ports are 1 in. diameter or $\frac{1}{12}$ of the piston area, and the mean velocity in the ports 6·4 ft. per sec. With 700 lb per sq. in. water pressure and an efficiency of 50%, the engine is about 3 h.p. A common arrangement is to have three parallel cylinders acting on a three-throw crank shaft, the cylinders oscillating on trunnions.

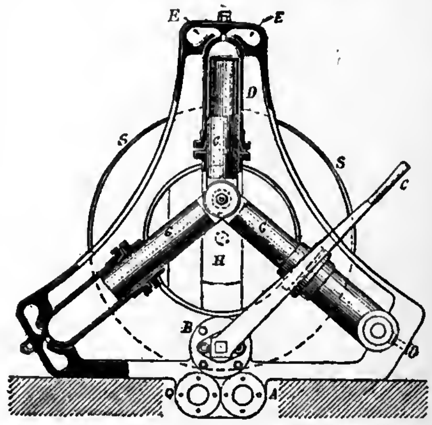

FIG. 173.

Hastie's Engine.—Fig. 173 shows a similar engine made by Messrs Hastie of Greenock. G, G, G are the three plungers which pass out of the cylinders through cup leathers, and act on the same crank pin. A is the inlet pipe which communicates with the cock B. This cock controls the action of the engine, being so constructed that it acts as a reversing valve when the handle C is in its extreme positions and as a brake when in its middle position. With the handle in its middle position, the ports of the cylinders are in communication with the exhaust. Two passages are formed in the framing leading from the cock B to the ends of the cylinders, one being in communication with the supply pipe A, the other with the discharge pipe Q. These passages end as shown at E. The oscillation of the cylinders puts them alternately in communication with each of these passages, and thus the water is alternately admitted and exhausted.

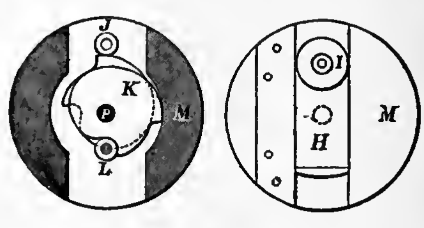

FIG. 174.

In any ordinary rotative engine the length of stroke is invariable. Consequently the consumption of water depends simply on the speed of the engine, irrespective of the effort overcome. If the power of the engine must be varied without altering the number of rotations, then the stroke must be made variable. Messrs Hastie have contrived an exceedingly ingenious method of varying the stroke automatically, in proportion to the amount of work to be done (fig. 174). The crank pin I is carried in a slide H moving in a disk M. In this is a double cam K acting on two small steel rollers J, L attached to the slide H. If the cam rotates it moves the slide and increases or decreases the radius of the circle in which the crank pin I rotates. The disk M is keyed on a hollow shaft surrounding the driving shaft P, to which the cams are attached. The hollow shaft N has two snugs to which the chains RR are attached (fig. 175). The shaft P carries the spring case SS to which also are attached the other ends of the chains. When the engine is at rest the springs extend themselves, rotating the hollow shaft N and the frame M, so as to place the crank pin I at its nearest position to the axis of rotation. When a resistance has to be overcome, the shaft N rotates

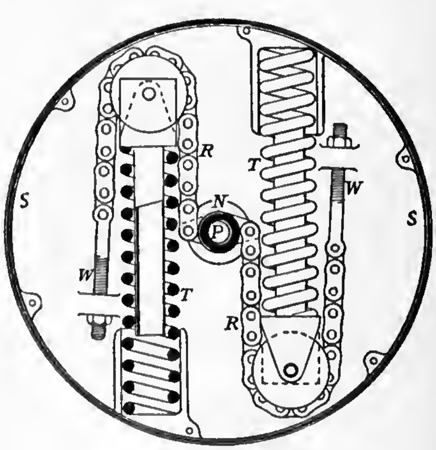

FIG. 175.

relatively to P, compressing the springs, till their resistance balances the pressure due to the resistance to the rotation of P. The engine then commences to work, the crank pin being in the position in which the turning effort just overcomes the resistance. If the resistance diminishes, the springs force out the chains and shorten the stroke of the plungers, and vice versa. The following experiments, on an engine of this kind working a hoist, show how the automatic arrangement adjusted the water used to the work done. The lift was 22 ft. and the water pressure in the cylinders 80 ℔ per sq. in.

Weight lifted, in ℔	Chain only	427	633	745	857	969	1081	1193
Water used, in gallons	$7\frac{1}{2}$	10	14	16	17	20	21	22

§ 179. *Accumulator Machinery.*—It has already been pointed out that it is in some cases convenient to use a steam engine to create an artificial head of water, which is afterwards employed in driving water-pressure machinery. Where power is required intermittently, for short periods, at a number of different points, as, for instance, in moving the cranes, lock gates, &c., of a dockyard, a separate steam engine and boiler at each point is very inconvenient; nor can engines worked from a common boiler be used, because of the great loss of heat and the difficulties which arise out of condensation in the pipes. If a tank, into which water is continuously pumped, can be placed at a great elevation, the water can then be used in hydraulic machinery in a very convenient way. Each hydraulic machine is put in communication with the tank by a pipe, and on opening a valve it commences work, using a quantity of water directly proportional to the work done. No attendance is required when the machine is not working.

A site for such an elevated tank is, however, seldom available, and in place of it a beautiful arrangement termed an accumulator, invented by Lord Armstrong, is used. This consists of a tall vertical cylinder; into this works a solid ram through cup leathers or hemp packing, and the ram is loaded by fixed weights, so that the pressure in the cylinder is 700 ℔ or 800 ℔ per sq. in. In some cases the ram is fixed and the cylinder moves on it. The pumping engines which supply the energy that is stored in the accumulator should be a pair coupled at right angles, so as to start in any position. The engines pump into the accumulator cylinder till the ram is at the top of its stroke, when by a catch arrangement acting on the engine throttle valve the engines are stopped. If the accumulator ram descends, in consequence of water being taken to work machinery, the engines immediately recommence working. Pipes lead from the accumulator to each of the machines requiring to be driven, and do not require to be of large size, as the pressure is so great.

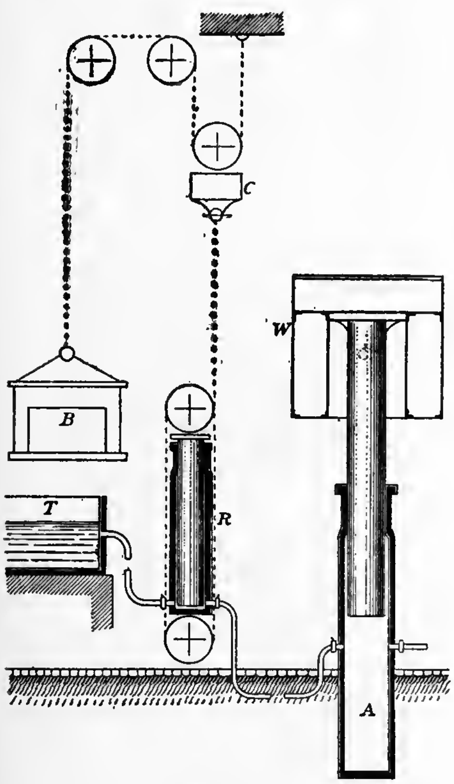

Fig. 176.

Fig. 176 shows a diagrammatic way the scheme of a system of accumulator machinery. A is the accumulator, with its ram carrying a cylindrical wrought-iron tank W, in which weights are placed to load the accumulator. At R is one of the pressure engines or jiggers, worked from the accumulator, discharging the water after use into the tank T. In this case the pressure engine is shown working a set of blocks, the fixed block being on the ram cylinder, the running block on the ram. The chain running over these blocks works a lift cage C, the speed of which is as many times greater than that of the ram as there are plies of chain on the block tackle. B is the balance weight of the cage.

In the use of accumulators on shipboard for working gun gear or steering gear, the accumulator ram is loaded by springs, or by steam pressure acting on a piston much larger than the ram.

R. H. Tweddell has used accumulators with a pressure of 2000 ℔ per sq. in. to work hydraulic riveting machinery.

The amount of energy stored in the accumulator, having a ram d in. in diameter, a stroke of S ft., and delivering at p ℔ pressure per sq. in., is

$$\frac{\pi}{4}pd^2S \text{ foot-pounds.}$$

Thus, if the ram is 9 in., the stroke 20 ft., and the pressure 800 ℔ per sq. in., the work stored in the accumulator when the ram is at the top of the stroke is 1,017,600 foot-pounds, that is, enough to drive a machine requiring one horse power for about half an hour. As, however, the pumping engine replaces water as soon as it is drawn off, the working capacity of the accumulator is very much greater than this. Tweddell found that an accumulator charged at 1250 ℔ discharged at 1225 ℔ per sq. in. Hence the friction was equivalent to $12\frac{1}{2}$ ℔ per sq. in. and the efficiency 98 %.

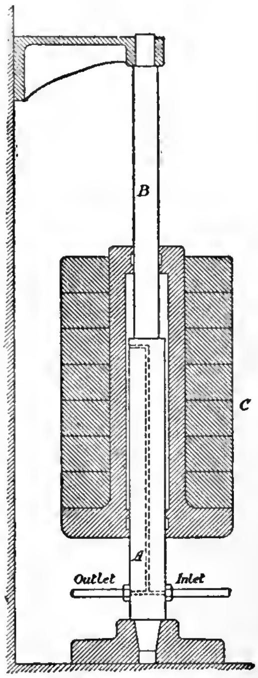

Fig. 177.

When a very great pressure is required a differential accumulator (fig. 177) is convenient. The ram is fixed and passes through both ends of the cylinder, but is of different diameters at the two ends, A and B. Hence if d_1, d_2 are the diameters of the ram in inches and p the required pressure in ℔ per sq. in., the load required is $\frac{1}{4}p\pi(d^2_1-d^2_2)$. An accumulator of this kind used with riveting machines has $d_1=5\frac{1}{2}$ in., $d_2=4\frac{3}{4}$in. The pressure is 2000 ℔ per sq. in. and the load 5·4 tons.

Sometimes an accumulator is loaded by water or steam pressure instead of by a dead weight. Fig. 178 shows the arrangement. A piston A is connected to a plunger B of much smaller area. Water pressure, say from town mains, is admitted below A, and the high pressure water is pumped into and discharged from the cylinder C in which B works. If r is the ratio of the areas of A and B, then, neglecting friction, the pressure in the upper cylinder is r times that under the piston A. With a variable rate of supply and demand from the upper cylinder, the piston A rises and falls, maintaining always a constant pressure in the upper cylinder.

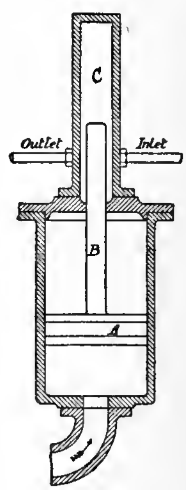

Fig. 178.

Water Wheels.

§ 180. *Overshot and High Breast Wheels.*—When a water fall ranges between 10 and 70 ft. and the water supply is from 3 to 25 cub. ft. per second, it is possible to construct a bucket wheel on which the water acts chiefly by its weight. If the variation of the head-water level does not exceed 2 ft., an overshot wheel may be used (fig. 179). The water is then projected over the summit of the wheel, and falls in a parabolic path into the buckets. With greater variation of head-water level, a pitch-back or high breast wheel is better. The water falls over the top of a sliding sluice into the wheel, on the same side as the head race channel. By adjusting the height of the sluice, the requisite supply is given to the wheel in all positions of the head-water level.

The wheel consists of a cast-iron or wrought-iron axle C supporting the weight of the wheel. To this are attached two sets of arms A of wood or iron, which support circular segmental plates, B, termed shrouds. A cylindrical sole plate *dd* extends between the shrouds on the inner side. The buckets are formed

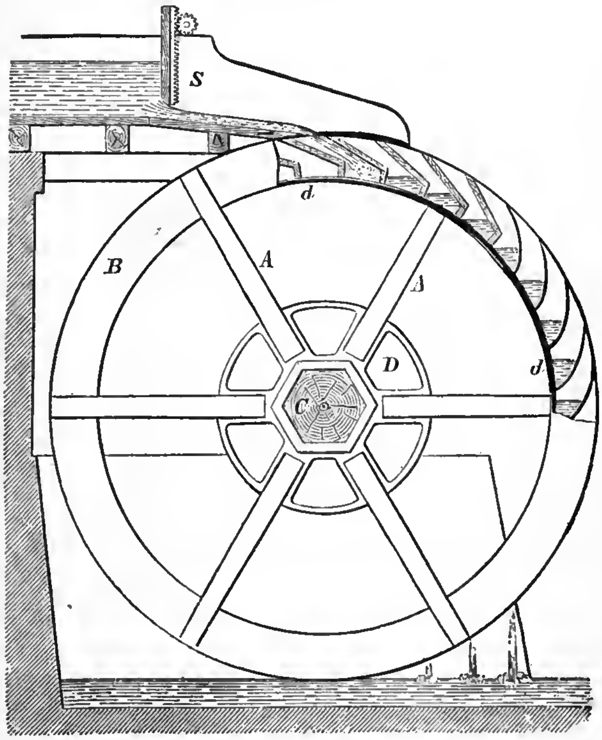

FIG. 179.

by wood planks or curved wrought-iron plates extending from shroud to shroud, the back of the buckets being formed by the sole plate.

The efficiency may be taken at 0·75. Hence, if *h.p.* is the effective horse power, H the available fall, and Q the available water supply per second,

$$h.\ p. = 0{\cdot}75(\text{GQH}/550) = 0{\cdot}085\ \text{QH}.$$

If the peripheral velocity of the water wheel is too great, water is thrown out of the buckets before reaching the bottom of the fall. In practice, the circumferential velocity of water wheels of the kind now described is from $4\frac{1}{2}$ to 10 ft. per second, about 6 ft. being the usual velocity of good iron wheels not of very small size. In order that the water may enter the buckets easily, it must have a greater velocity than the wheel. Usually the velocity of the water at the point where it enters the wheel is from 9 to 12 ft. per second, and to produce this it must enter the wheel at a point 16 to 27 in. below the head-water level. Hence the diameter of an overshot wheel may be

$$D = H - 1\tfrac{1}{3} \text{ to } H - 2\tfrac{1}{4} \text{ ft.}$$

Overshot and high breast wheels work badly in back-water, and hence if the tail-water level varies, it is better to reduce the diameter of the wheel so that its greatest immersion in flood is not more than 1 ft. The depth *d* of the shrouds is about 10 to 16 in. The number of buckets may be about

$$N = \pi D/d.$$

Let v be the peripheral velocity of the wheel. Then the capacity of that portion of the wheel which passes the sluice in one second is

$$Q_1 = vb(Dd - d^2)/D$$
$$= v\ b\ d \text{ nearly,}$$

b being the breadth of the wheel between the shrouds. If, however, this quantity of water were allowed to pass on to the wheel the buckets would begin to spill their contents almost at the top of the fall. To diminish the loss from spilling, it is not only necessary to give the buckets a suitable form, but to restrict the water supply to one-fourth or one-third of the gross bucket capacity. Let m be the value of this ratio; then, Q being the supply of water per second,

$$Q = mQ_1 = mbdv.$$

This gives the breadth of the wheel if the water supply is known. The form of the buckets should be determined thus. The outer element of the bucket should be in the direction of motion of the water entering relatively to the wheel, so that the water may enter without splashing or shock. The buckets should retain the water as long as possible, and the width of opening of the buckets should be 2 or 3 in. greater than the thickness of the sheet of water entering.

For a wooden bucket (fig. 180, A), take ab = distance between two buckets on periphery of wheel. Make $ed = \frac{1}{2}\,eb$, and $bc = \frac{5}{8}$ to $\frac{3}{4}\,ab$. Join cd. For an iron bucket (fig. 180, B), take $ed = \frac{1}{3}\,eb$; $bc = \frac{5}{8}ab$. Draw cO making an angle of 10° to 15° with the radius at c. On Oc take a centre giving a circular arc passing near d, and round the curve into the radial part of the bucket de.

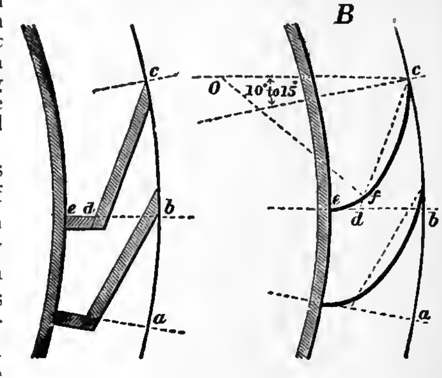

FIG. 180.

There are two ways in which the power of a water wheel is given off to the machinery driven. In wooden wheels and wheels with rigid arms, a spur or bevil wheel keyed on the axle of the turbine will transmit the power to the shafting. It is obvious that the whole turning moment due to the weight of the water is then transmitted through the arms and axle of the water wheel. When the water wheel is an iron one, it usually has light iron suspension arms incapable of resisting the bending action due to the transmission of the turning effort to the axle. In that case spur segments are bolted to one of the shrouds, and the pinion to which the power is transmitted is placed so that the teeth in gear are, as nearly as may be, on the line of action of the resultant of the weight of the water in the loaded arc of the wheel.

The largest high breast wheels ever constructed were probably the four wheels, each 50 ft. in diameter, and of 125 h.p., erected by Sir W. Fairbairn in 1825 at Catrine in Ayrshire. These wheels are still working.

§ 181. *Poncelet Water Wheel.*—When the fall does not exceed 6 ft., the best water motor to adopt in many cases is the Poncelet undershot water wheel. In this the water acts very nearly in the same way as in a turbine, and the Poncelet wheel, although slightly less efficient than the best turbines, in normal conditions of working, is superior to most of them when working with a reduced supply of water. A general notion of the action of the water on a Poncelet wheel has already been given in § 159. Fig. 181 shows its construction. The water penned back between the side walls of the wheel pit is allowed to flow to the

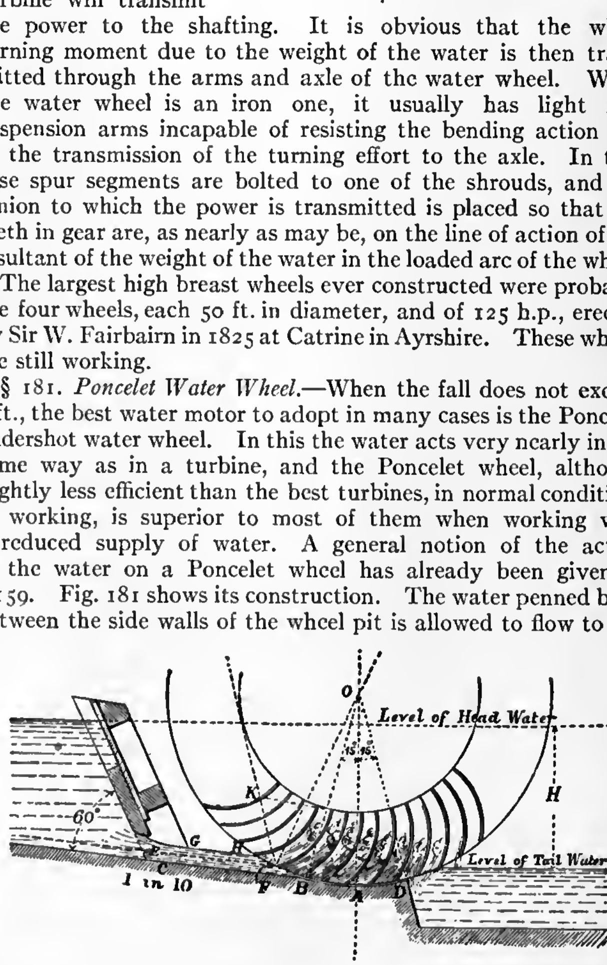

FIG. 181.

wheel under a movable sluice, at a velocity nearly equal to the velocity due to the whole fall. The water is guided down a slope of 1 in 10, or a curved race, and enters the wheel without shock. Gliding up the curved floats it comes to rest, falls back, and acquires at the point of discharge a backward velocity relative to the wheel nearly equal to the forward velocity of the wheel. Consequently it leaves the wheel deprived of nearly the whole of its original kinetic energy.

Taking the efficiency at 0·60, and putting H for the available fall, *h.p.* for the horse-power, and Q for the water supply per second,

$$h.p. = 0{\cdot}068\ \text{QH}.$$

The diameter D of the wheel may be taken arbitrarily. It should not be less than twice the fall and is more often four times the fall. For ordinary cases the smallest convenient diameter is 14 ft. with a straight, or 10 ft. with a curved, approach channel. The radial depth of bucket should be at least half the fall, and radius of curvature of buckets about half the radius of the wheel. The shrouds are usually of cast iron with flanges to receive the buckets. The buckets may be of iron $\frac{1}{8}$ in. thick bolted to the flanges with $\frac{5}{16}$ in. bolts.

Let H′ be the fall measured from the free surface of the head-water to the point F where the mean layer enters the wheel; then the velocity at which the water enters is $v = \sqrt{(2gH')}$, and the best circumferential velocity of the wheel is $V = 0{\cdot}55v$ to $0{\cdot}6v$. The number of rotations of the wheel per second is $N = V/\pi D$. The thickness of the sheet of water entering the wheel is very important. The best thickness according to experiment is 8 to 10 in. The maximum thickness should not exceed 12 to 15 in., when there is a surplus water supply. Let e be the thickness of the sheet of water entering the wheel, and b its width; then

$$bev = Q;\ \text{or}\ b = Q/ev.$$

Grashof takes $e = \frac{1}{6}H$, and then

$$b = 6Q/H\sqrt{(2gH)}.$$

Allowing for the contraction of the stream, the area of opening through the sluice may be $1{\cdot}25\ be$ to $1{\cdot}3\ be$. The inside width of the wheel is made about 4 in. greater than b.

Several constructions have been given for the floats of Poncelet wheels. One of the simplest is that shown in figs. 181, 182.

Let OA (fig. 181) be the vertical radius of the wheel. Set off OB, OD making angles of 15° with OA. Then BD may be the length of

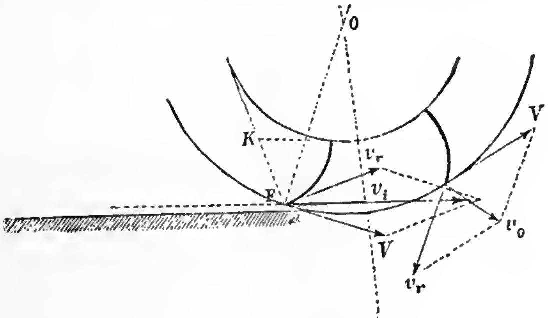

FIG. 182.

the close breasting fitted to the wheel. Draw the bottom of the head race BC at a slope of 1 in 10. Parallel to this, at distances $\frac{1}{2}e$ and e, draw EF and GH. Then EF is the mean layer and GH the surface layer entering the wheel. Join OF, and make OFK=23°. Take FK=0·5 to 0·7 H. Then K is the centre from which the bucket curve is struck and KF is the radius. The depth of the shrouds must be sufficient to prevent the water from rising over the top of the float. It is $\frac{1}{2}$H to $\frac{2}{3}$H. The number of buckets is not very important. They are usually 1 ft. apart on the circumference of the wheel.

The efficiency of a Poncelet wheel has been found in experiments to reach 0·68. It is better to take it at 0·6 in estimating the power of the wheel, so as to allow some margin.

In fig. 182 v_i is the initial and v_o the final velocity of the water, v_r parallel to the vane the relative velocity of the water and wheel, and V the velocity of the wheel.

Turbines.

§ 182. The name turbine was originally given in France to any water motor which revolved in a horizontal plane, the axis being vertical. The rapid development of this class of motors dates from 1827, when a prize was offered by the Société d'Encouragement for a motor of this kind, which should be an improvement on certain wheels then in use. The prize was ultimately awarded to Benoît Fourneyron (1802–1867), whose turbine, but little modified, is still constructed.

Classification of Turbines.—In some turbines the whole available energy of the water is converted into kinetic energy before the water acts on the moving part of the turbine. Such turbines are termed *Impulse* or *Action Turbines*, and they are distinguished by this that the wheel passages are never entirely filled by the water. To ensure this condition they must be placed a little above the tail water and discharge into free air. Turbines in which part only of the available energy is converted into kinetic energy before the water enters the wheel are termed *Pressure* or *Reaction Turbines*. In these there is a pressure which in some cases amounts to half the head in the clearance space between the guide vanes and wheel vanes. The velocity with which the water enters the wheel is due to the difference between the pressure due to the head and the pressure in the clearance space. In pressure turbines the wheel passages must be continuously filled with water for good efficiency, and the wheel may be and generally is placed below the tail water level.

Some turbines are designed to act normally as impulse turbines discharging above the tail water level. But the passages are so designed that they are just filled by the water. If the tail water rises and drowns the turbine they become pressure turbines with a small clearance pressure, but the efficiency is not much affected. Such turbines are termed *Limit turbines*.

Next there is a difference of constructive arrangement of turbines, which does not very essentially alter the mode of action of the water. In axial flow or so-called parallel flow turbines, the water enters and leaves the turbine in a direction parallel to the axis of rotation, and the paths of the molecules lie on cylindrical surfaces concentric with that axis. In radial outward and inward flow turbines, the water enters and leaves the turbine in directions normal to the axis of rotation, and the paths of the molecules lie exactly or nearly in planes normal to the axis of rotation. In outward flow turbines the general direction of flow is away from the axis, and in inward flow turbines towards the axis. There are also mixed flow turbines in which the water enters normally and is discharged parallel to the axis of rotation.

Another difference of construction is this, that the water may be admitted equally to every part of the circumference of the turbine wheel or to a portion of the circumference only. In the former case, the condition of the wheel passages is always the same; they receive water equally in all positions during rotation. In the latter case, they receive water during a part of the rotation only. The former may be termed turbines with complete admission, the latter turbines with partial admission. A reaction turbine should always have complete admission. An impulse turbine may have complete or partial admission.

When two turbine wheels similarly constructed are placed on the same axis, in order to balance the pressures and diminish journal friction, the arrangement may be termed a twin turbine.

If the water, having acted on one turbine wheel, is then passed through a second on the same axis, the arrangement may be termed a compound turbine. The object of such an arrangement would be to diminish the speed of rotation.

Many forms of reaction turbine may be placed at any height not exceeding 30 ft. above the tail water. They then discharge into an air-tight suction pipe. The weight of the column of water in this pipe balances part of the atmospheric pressure, and the difference of pressure, producing the flow through the turbine, is the same as if the turbine were placed at the bottom of the fall.

I. *Impulse Turbines.*	II. *Reaction Turbines.*
(Wheel passages not filled, and discharging above the tail water.)	(Wheel passages filled, discharging above or below the tail water or into a suction-pipe.)
(*a*) Complete admission. (Rare.) (*b*) Partial admission. (Usual.)	Always with complete admission.

Axial flow, outward flow, inward flow, or mixed flow.

Simple turbines; twin turbines; compound turbines.

§ 183. *The Simple Reaction Wheel.*—It has been shown, in § 162, that, when water issues from a vessel, there is a reaction on the vessel tending to cause motion in a direction opposite to that of the jet. This principle was applied in a rotating water motor at a very early period, and the Scotch turbine, at one time much used, differs in no essential respect from the older form of reaction wheel.

The old reaction wheel consisted of a vertical pipe balanced on a vertical axis, and supplied with water (fig. 183). From the bottom of the vertical pipe two or more hollow horizontal arms extended, at the ends of which were orifices from which the water was discharged. The reaction of the jets caused the rotation of the machine.

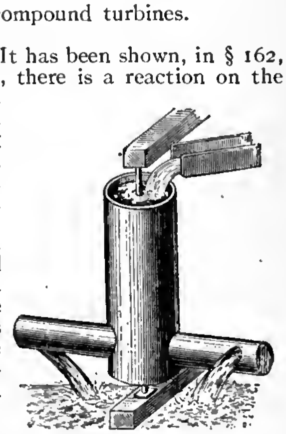

FIG. 183.

Let H be the available fall measured from the level of the water in the vertical pipe to the centres of the orifices, r the radius from the axis of rotation to the centres of the orifices, v the velocity of discharge through the jets, α the angular velocity of the machine. When the machine is at rest the water issues from the orifices with the velocity $\sqrt{(2gH)}$ (friction being neglected). But when the machine rotates the water in the arms rotates also, and is in the condition of a forced vortex, all the particles having the same angular velocity. Consequently the pressure in the arms at the orifices is $H+a^2r^2/2g$ ft. of water, and the velocity of discharge through the orifices is $v=\sqrt{(2gH+a^2r^2)}$. If the total area of the orifices is ω, the quantity discharged from the wheel per second is

$$Q=\omega v=\omega\sqrt{(2gH+a^2r^2)}.$$

While the water passes through the orifices with the velocity v, the orifices are moving in the opposite direction with the velocity ar. The absolute velocity of the water is therefore

$$v-ar=\sqrt{(2gH+a^2r^2)}-ar.$$

The momentum generated per second is $(GQ/g)(v-ar)$, which is numerically equal to the force driving the motor at the radius r. The work done by the water in rotating the wheel is therefore

$$(GQ/g)(v-ar)ar \text{ foot-pounds per sec.}$$

The work expended by the water fall is GQH foot-pounds per second. Consequently the efficiency of the motor is

$$\eta=\frac{(v-ar)\,ar}{gH}=\frac{\{\sqrt{2gH+a^2r^2}-ar\}ar}{gH}.$$

Let $$\sqrt{2gH+a^2r^2}=ar+\frac{gH}{ar}-\frac{g^2H^2}{2a^3r^3}\ldots$$

then $$\eta=1-gH/2ar+\ldots$$

which increases towards the limit 1 as ar increases towards infinity. Neglecting friction, therefore, the maximum efficiency is reached when the wheel has an infinitely great velocity of rotation. But this condition is impracticable to realize, and even, at practicable but high velocities of rotation, the friction would considerably reduce the efficiency. Experiment seems to show that the best efficiency is reached when $ar=\sqrt{(2gH)}$. Then the efficiency apart from friction is

$$\eta=\{\sqrt{(2a^2r^2)}-ar\}ar/gH$$
$$=0{\cdot}414a^2r^2/gH=0{\cdot}828,$$

about 17% of the energy of the fall being carried away by the water discharged. The actual efficiency realized appears to be about 60%, so that about 21% of the energy of the fall is lost in friction, in addition to the energy carried away by the water.

§ 184. *General Statement of Hydrodynamical Principles necessary for the Theory of Turbines.*

(*a*) When water flows through any pipe-shaped passage, such as the passage between the vanes of a turbine wheel, the relation between the changes of pressure and velocity is given by Bernoulli's theorem (§ 29). Suppose that, at a section A of such a passage, h_1 is the pressure measured in feet of water, v_1 the velocity, and z_1 the elevation above any horizontal datum plane, and that at a section B the same quantities are denoted by h_2, v_2, z_2. Then

$$h_1-h_2=(v_2^2-v_1^2)/2g+z_2-z_1. \qquad (1)$$

If the flow is horizontal, $z_2=z_1$; and

$$h_1-h_2=(v_2^2-v_1^2)/2g. \qquad (1a)$$

(*b*) When there is an abrupt change of section of the passage, or an abrupt change of section of the stream due to a contraction, then, in applying Bernoulli's equation allowance must be made for the loss of head in shock (§ 36). Let v_1, v_2 be the velocities before and after the abrupt change, then a stream of velocity v_1 impinges on a stream at a velocity v_2, and the relative velocity is v_1-v_2. The head lost is $(v_1-v_2)^2/2g$. Then equation (1*a*) becomes

$$h_2-h_1=(v_1^2-v_2^2)/2g-(v_1-v_2)^2/2g=v_2(v_1-v_2)/g. \qquad (2)$$

To diminish as much as possible the loss of energy from irregular eddying motions, the change of section in the turbine passages must be very gradual, and the curvature without discontinuity.

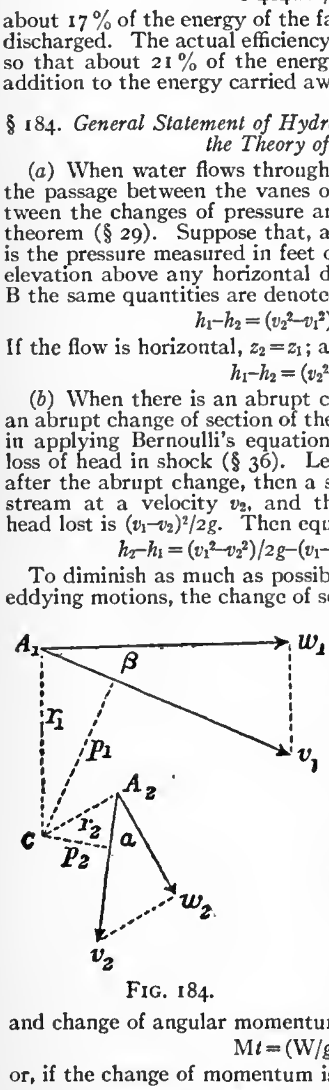

Fig. 184.

(*c*) *Equality of Angular Impulse and Change of Angular Momentum.*—Suppose that a couple, the moment of which is M, acts on a body of weight W for t seconds, during which it moves from A_1 to A_2 (fig. 184). Let v_1 be the velocity of the body at A_1, v_2 its velocity at A_2, and let p_1, p_2 be the perpendiculars from C on v_1 and v_2. Then Mt is termed the angular impulse of the couple, and the quantity

$$(W/g)(v_2p_2-v_1p_1)$$

is the change of angular momentum relatively to C. Then, from the equality of angular impulse and change of angular momentum

$$Mt=(W/g)(v_2p_2-v_1p_1),$$

or, if the change of momentum is estimated for one second,

$$M=(W/g)(v_2p_2-v_1p_1).$$

Let r_1, r_2 be the radii drawn from C to A_1, A_2, and let w_1, w_2 be the components of v_1, v_2, perpendicular to these radii, making angles β and a with v_1, v_2. Then

$$v_1=w_1\sec\beta;\ v_2=w_2\sec a;$$
$$p_1=r_1\cos\beta;\ p_2=r_2\cos a.$$
$$\therefore M=(W/g)(w_2r_2-w_1r_1), \qquad (3)$$

where the moment of the couple is expressed in terms of the radii drawn to the positions of the body at the beginning and end of a second, and the tangential components of its velocity at those points.

Now the water flowing through a turbine enters at the admission surface and leaves at the discharge surface of the wheel, with its angular momentum relatively to the axis of the wheel changed. It therefore exerts a couple $-M$ tending to rotate the wheel, equal and opposite to the couple M which the wheel exerts on the water. Let Q cub. ft. enter and leave the wheel per second, and let w_1, w_2 be the tangential components of the velocity of the water at the receiving and discharging surfaces of the wheel, r_1, r_2 the radii of those surfaces By the principle above,

$$-M=(GQ/g)(w_2r_2-w_1r_1). \qquad (4)$$

If a is the angular velocity of the wheel, the work done by the water on the wheel is

$$T=Ma=(GQ/g)(w_1r_1-w_2r_2)a \text{ foot-pounds per second.} \qquad (5)$$

§ 185. *Total and Available Fall.*—Let H_t be the total difference of level from the head-water to the tail-water surface. Of this total head a portion is expended in overcoming the resistances of the head race, tail race, supply pipe, or other channel conveying the water. Let $\mathfrak{h}_p$ be that loss of head, which varies with the local conditions in which the turbine is placed. Then

$$H=H_t-\mathfrak{h}_p$$

is the available head for working the turbine, and on this the calculations for the turbine should be based. In some cases it is necessary to place the turbine above the tail-water level, and there is then a fall $\mathfrak{h}$ from the centre of the outlet surface of the turbine to the tail-water level which is wasted, but which is properly one of the losses belonging to the turbine itself. In that case the velocities of the water in the turbine should be calculated for a head $H-\mathfrak{h}$, but the efficiency of the turbine for the head H.

§ 186. *Gross Efficiency and Hydraulic Efficiency of a Turbine.*—Let T_d be the useful work done by the turbine, in foot-pounds per second, T_t the work expended in friction of the turbine shaft, gearing, &c., a quantity which varies with the local conditions in which the turbine is placed. Then the effective work done by the water in the turbine is

$$T=T_d+T_t.$$

The gross efficiency of the whole arrangement of turbine, races, and transmissive machinery is

$$\eta_t=T_d/GQH_t. \qquad (6)$$

And the hydraulic efficiency of the turbine alone is

$$\eta=T/GQH. \qquad (7)$$

It is this last efficiency only with which the theory of turbines is concerned.

From equations (5) and (7) we get

$$\eta GQH=(GQ/g)(w_1r_1-w_2r_2)a;$$
$$\eta=(w_1r_1-w_2r_2)a/gH. \qquad (8)$$

This is the fundamental equation in the theory of turbines. In general,[1] w_1 and w_2, the tangential components of the water's motion on entering and leaving the wheel, are completely independent. That the efficiency may be as great as possible, it is obviously necessary that $w_2=0$. In that case

$$\eta=w_1r_1a/gH. \qquad (9)$$

ar_1 is the circumferential velocity of the wheel at the inlet surface. Calling this V_1, the equation becomes

$$\eta=w_1V_1/gH. \qquad (9a)$$

This remarkably simple equation is the fundamental equation in the theory of turbines. It was first given by Reiche (*Turbinenbaues*, 1877).

§ 187. *General Description of a Reaction Turbine.*—Professor James Thomson's inward flow or vortex turbine has been selected as the type of reaction turbines. It is one of the best in normal conditions of working, and the mode of regulation introduced is decidedly superior to that in most reaction turbines. Figs. 185 and 186 are external views of the turbine case; figs. 187 and 188 are the corresponding sections; fig. 189 is the turbine wheel. The example chosen for illustration has suction pipes, which permit the turbine to be placed above the tail-water level. The water enters the turbine by cast-iron supply pipes at A, and is discharged through two suction pipes S, S. The water

[1] In general, because when the water leaves the turbine wheel it ceases to act on the machine. If deflecting vanes or a whirlpool are added to a turbine at the discharging side, then v_1 may in part depend on v_2, and the statement above is no longer true.

on entering the case distributes itself through a rectangular supply chamber SC, from which it finds its way equally to the four guide-blade passages G, G, G, G. In these passages it

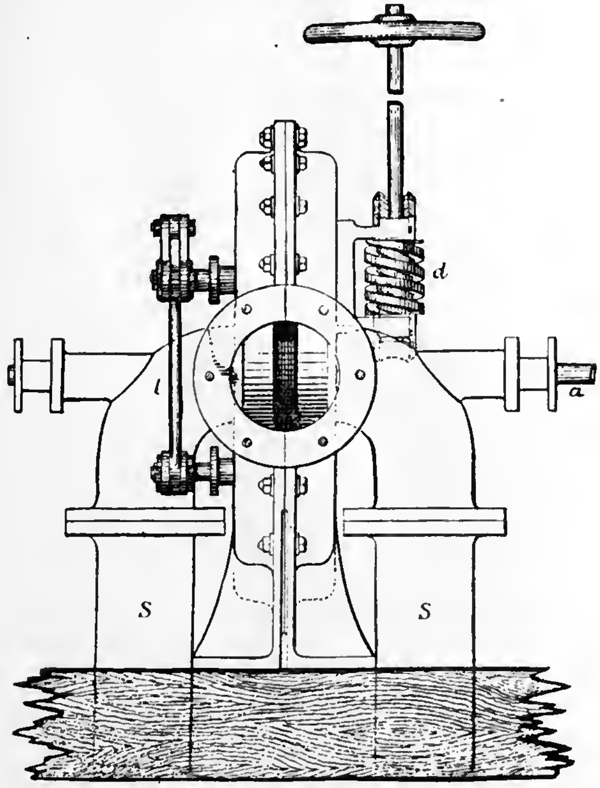

FIG. 185.

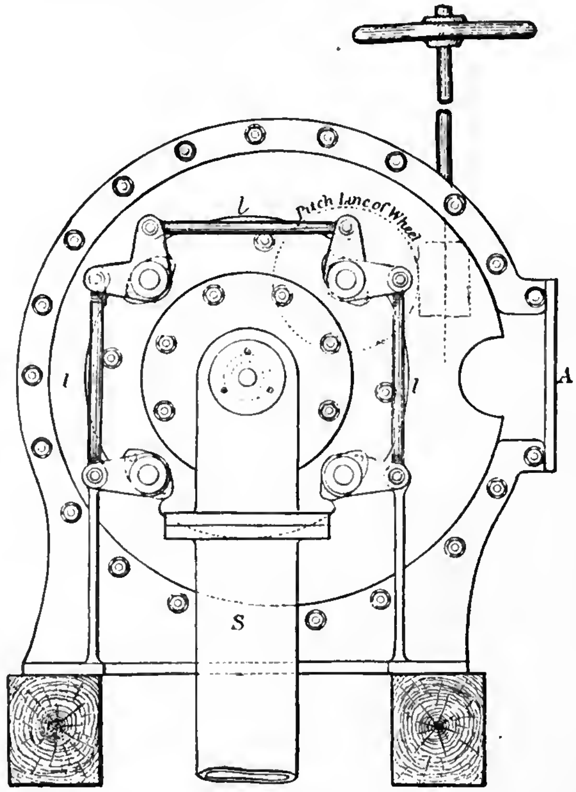

FIG. 186.

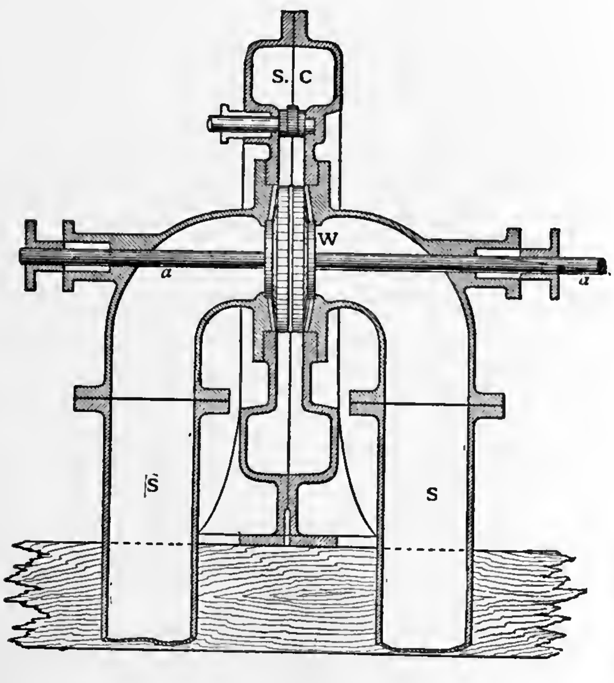

FIG. 187.

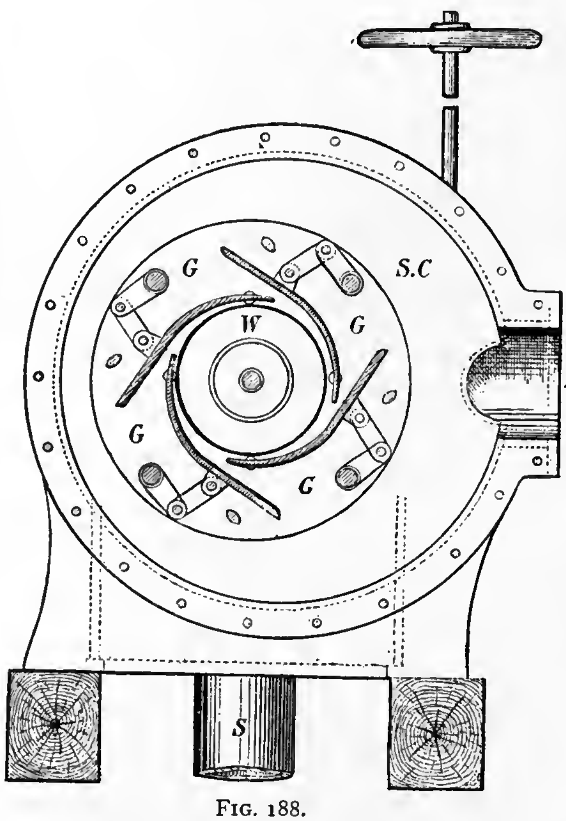

FIG. 188.

acquires a velocity about equal to that due to half the fall, and is directed into the wheel at an angle of about 10° or 12° with the tangent to its circumference. The wheel W receives the water in equal proportions from each guide-blade passage. It consists of a centre plate *p* (fig. 189) keyed on the shaft *aa*, which passes through stuffing boxes on the suction pipes. On each side of the centre plate are the curved wheel vanes, on which the pressure of the water acts, and the vanes are bounded on each side by dished or conical cover plates *c*, *c*. Joint-rings *j*, *j* on the cover plates make a sufficiently water-tight joint with the casing, to prevent leakage from the guide-blade chamber into the suction pipes. The pressure near the joint rings is not very great, probably not one-fourth the total head. The wheel vanes receive the water without shock, and deliver it into central spaces, from which it flows on either side to the suction pipes. The mode of regulating the power of the turbine is very simple. The guide-blades are pivoted to the case at their inner ends, and they are connected by a link-work, so that they all open and close simultaneously and equally. In this way the area of opening through the guide-blades is altered without materially altering the angle or the other conditions of the delivery into the wheel. The guide-blade gear may be variously arranged. In this example four spindles, passing through the case, are linked to the guide-blades inside the case, and connected together by the links

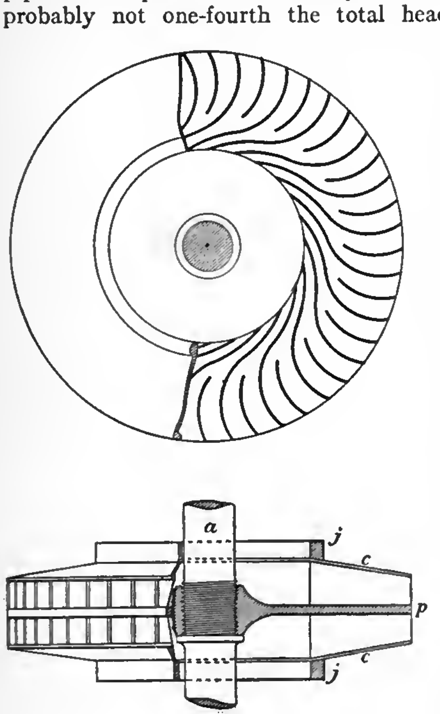

Fig. 189.

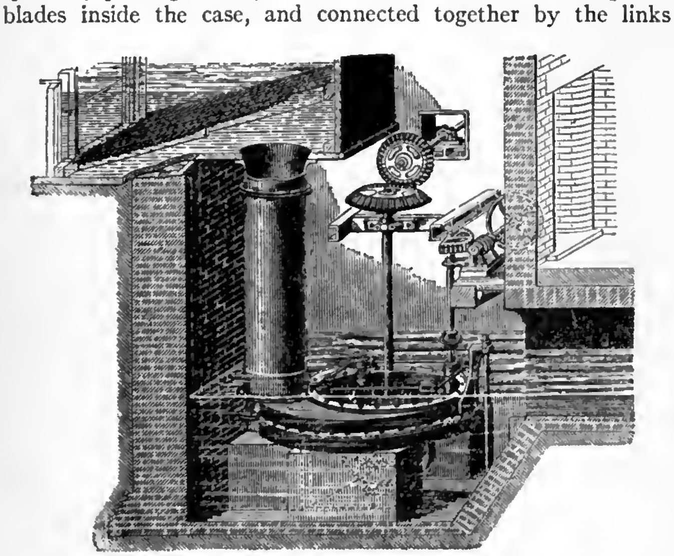

Fig. 190.

l, l, l on the outside of the case. A worm wheel on one of the spindles is rotated by a worm d, the motion being thus slow enough to adjust the guide-blades very exactly. These turbines are made by Messrs Gilkes & Co. of Kendal.

Fig. 190 shows another arrangement of a similar turbine, with some adjuncts not shown in the other drawings. In this case the turbine rotates horizontally, and the turbine case is placed entirely below the tail water. The water is supplied to the turbine by a vertical pipe, over which is a wooden pentrough, containing a strainer, which prevents sticks and other solid bodies getting into the turbine. The turbine rests on three foundation stones, and, the pivot for the vertical shaft being under water, there is a screw and lever arrangement for adjusting it as it wears. The vertical shaft gives motion to the machinery driven by a pair of bevel wheels. On the right are the worm and wheel for working the guide-blade gear.

§ 188. *Hydraulic Power at Niagara.*—The largest development of hydraulic power is that at Niagara. The Niagara Falls Power Company have constructed two power houses on the United States side, the first with 10 turbines of 5000 h.p. each, and the second with 10 turbines of 5500 h.p. The effective fall is 136 to 140 ft. In the first power house the turbines are twin outward flow reaction turbines with vertical shafts running at 250 revs. per minute and driving the dynamos direct. In the second power house the turbines

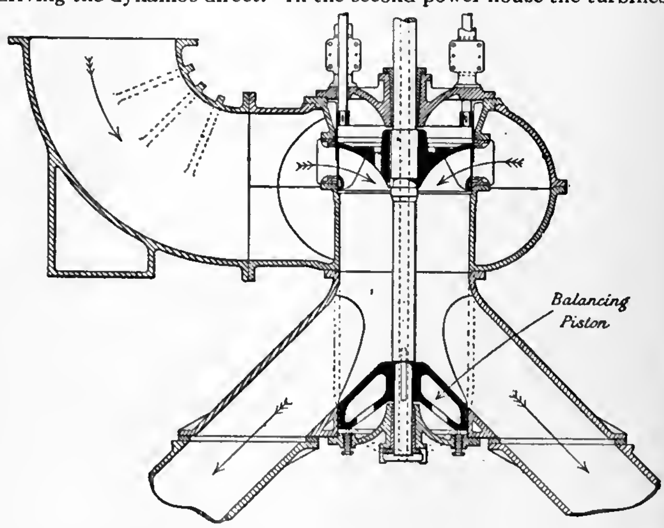

Fig. 191.

are inward flow turbines with draft tubes or suction pipes. Fig. 191 shows a section of one of these turbines. There is a balancing piston keyed on the shaft, to the under side of which the pressure due to the fall is admitted, so that the weight of turbine, vertical shaft and part of the dynamo is water borne. About 70,000 h.p. is daily distributed electrically from these two power houses. The Canadian Niagara Power Company are erecting a power house to contain eleven units of 10,250 h.p. each, the turbines being twin inward flow reaction turbines. The Electrical Development Company of Ontario are erecting a power house to contain 11 units of 12,500 h.p. each. The Ontario Power Company are carrying out another scheme for developing 200,000 h.p. by twin inward flow turbines of 12,000 h.p. each. Lastly the Niagara Falls Power and Manufacturing Company on the United States side have a station giving 35,000 h.p. and are constructing another to furnish 100,000 h.p. The mean flow of the Niagara river is about 222,000 cub. ft. per second with a fall of 160 ft. The works in progress if completed will utilize 650,000 h.p. and require 48,000 cub. ft. per second or $21\frac{1}{2}$% of the mean flow of the river (Unwin, "The Niagara Falls Power Stations," *Proc. Inst. Mech. Eng.*, 1906).

§ 189. *Different Forms of Turbine Wheel.*—The wheel of a turbine or part of the machine on which the water acts is an annular space, furnished with curved vanes dividing it into passages exactly or roughly rectangular in cross section. For radial flow turbines the wheel may have the form A or B, fig. 192, A being most usual with

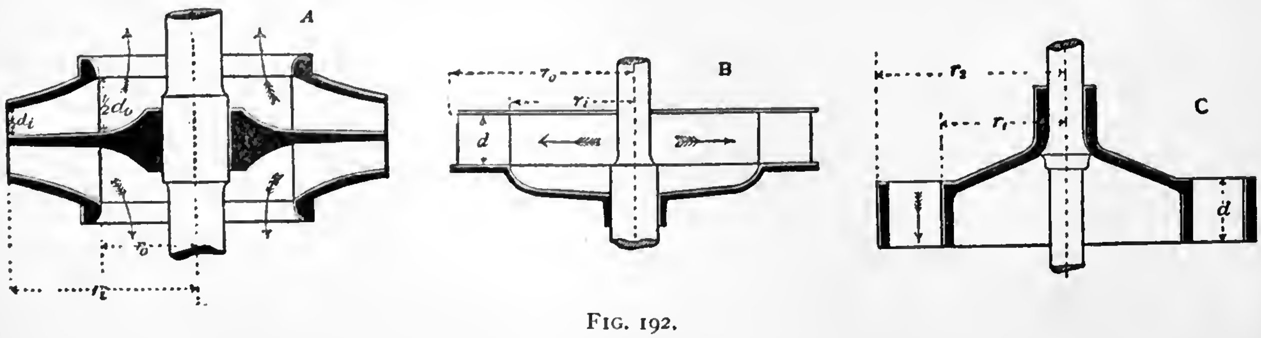

Fig. 192.

inward, and B with outward flow turbines. In A the wheel vanes are fixed on each side of a centre plate keyed on the turbine shaft. The vanes are limited by slightly-coned annular cover plates. In B the vanes are fixed on one side of a disk, keyed on the shaft, and limited by a cover plate parallel to the disk. Parallel flow or axial flow turbines have the wheel as in C. The vanes are limited by two concentric cylinders.

Theory of Reaction Turbines.

§ 190. *Velocity of Whirl and Velocity of Flow.*—Let acb (fig. 193) be the path of the particles of water in a turbine wheel. That path will be in a plane normal to the axis of rotation in radial flow turbines, and on a cylindrical surface in axial flow turbines. At any point c of the path the water will have some velocity v, in the direction of a tangent to the path. That velocity may be resolved into two components, a whirling velocity w in the direction of the wheel's rotation at the point c, and a component u at right angles to this, radial in radial flow, and parallel to the axis in axial flow turbines. This second component is termed the velocity of flow. Let v_o, w_o, u_o be the velocity of the water, the whirling velocity and velocity of flow at the outlet surface of the wheel, and v_i, w_i, v_i the same quantities at the inlet surface of the wheel. Let α and β be the angles which the water's direction of motion makes with the direction of motion of the wheel at those surfaces. Then

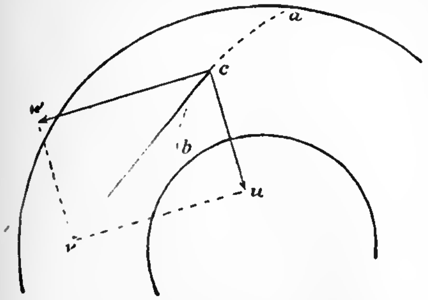

FIG. 193.

$$\left.\begin{array}{l} w_o=v_o\cos\beta;\ u_o=v_o\sin\beta \\ w_i=v_i\cos\alpha;\ u_i=v_i\sin\alpha \end{array}\right\}. \qquad (10)$$

The velocities of flow are easily ascertained independently from the dimensions of the wheel. The velocities of flow at the inlet and outlet surfaces of the wheel are normal to those surfaces. Let Ω_o, Ω_i be the areas of the outlet and inlet surfaces of the wheel, and Q the volume of water passing through the wheel per second; then

$$v_o=Q/\Omega_o;\ v_i=Q/\Omega_i. \qquad (11)$$

Using the notation in fig. 191, we have, for an inward flow turbine (neglecting the space occupied by the vanes),

$$\Omega_o=2\pi r_o d_o;\ \Omega_i=2\pi r_i d_i. \qquad (12a)$$

Similarly, for an outward flow turbine,

$$\Omega_o=2\pi r_o d;\ \Omega_i=2\pi r_i d; \qquad (12b)$$

and, for an axial flow turbine,

$$\Omega_o=\Omega_i=\pi(r_2^2-r_1^2). \qquad (12c)$$

Relative and Common Velocity of the Water and Wheel.—There is another way of resolving the velocity of the water. Let V be the velocity of the wheel at the point c, fig. 194. Then the velocity of the water may be resolved into a component V, which the water has in common with the wheel, and a component v_r, which is the velocity of the water relatively to the wheel.

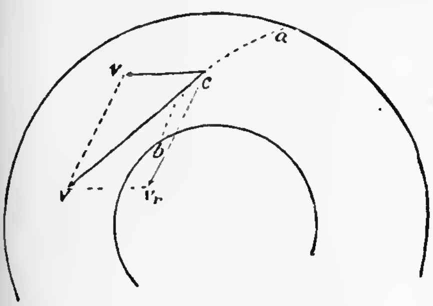

FIG. 194.

Velocity of Flow.—It is obvious that the frictional losses of head in the wheel passages will increase as the velocity of flow is greater, that is, the smaller the wheel is made. But if the wheel works under water, the skin friction of the wheel cover increases as the diameter of the wheel is made greater, and in any case the weight of the wheel and consequently the journal friction increase as the wheel is made larger. It is therefore desirable to choose, for the velocity of flow, as large a value as is consistent with the condition that the frictional losses in the wheel passages are a small fraction of the total head. The values most commonly assumed in practice are these:—

In axial flow turbines, $u_o=u_i=0{\cdot}15$ to $0{\cdot}2\sqrt{(2gH)}$;
In outward flow turbines, $u_i=0{\cdot}25\sqrt{2g(H-\mathfrak{h})}$,
$u_o=0{\cdot}21$ to $0{\cdot}17\sqrt{2g(H-\mathfrak{h})}$;
In inward flow turbines, $u_o=u_i=0{\cdot}125\sqrt{(2gH)}$.

§ 191. *Speed of the Wheel.*—The best speed of the wheel depends partly on the frictional losses, which the ordinary theory of turbines disregards. It is best, therefore, to assume for V_o and V_i values which experiment has shown to be most advantageous.

In axial flow turbines, the circumferential velocities at the mean radius of the wheel may be taken

$$V_o=V_i=0{\cdot}6\sqrt{2gH}\text{ to }0{\cdot}66\sqrt{2gH}.$$

In a radial outward flow turbine,

$$V_i=0{\cdot}56\sqrt{2g(H-\mathfrak{h})}$$
$$V_o=V_i r_o/r_i,$$

where r_o, r_i are the radii of the outlet and inlet surfaces.

In a radial inward flow turbine,

$$V_i=0{\cdot}66\sqrt{2gH},$$
$$V_o=V_i r_o/r_i.$$

If the wheel were stationary and the water flowed through it, the water would follow paths parallel to the wheel vane curves, at least when the vanes were so close that irregular motion was prevented. Similarly, when the wheel is in motion, the water follows paths relatively to the wheel, which are curves parallel to the wheel vanes. Hence the relative component, v_r, of the water's motion at c is tangential to a wheel vane curve drawn through the point c. Let v_o, V_o, v_{ro} be the velocity of the water and its common and relative components at the outlet surface of the wheel, and v_i, V_i, v_{ri} be the same quantities at the inlet surface; and let θ and ϕ be the angles the wheel vanes make with the inlet and outlet surfaces; then

$$\left.\begin{array}{l} v_o^2=\sqrt{(v_{ro}^2+V_o^2-2V_ov_{ro}\cos\phi)} \\ v_i\ =\sqrt{(v_{ri}^2+V_i^2-2V_iv_{ri}\cos\theta)} \end{array}\right\}, \qquad (13)$$

equations which may be used to determine ϕ and θ.

§ 192. *Condition determining the Angle of the Vanes at the Outlet Surface of the Wheel.*—It has been shown that, when the water leaves the wheel, it should have no tangential velocity, if the efficiency is to be as great as possible; that is, $w_o=0$. Hence, from (10), $\cos\beta=0$, $\beta=90°$, $u_o=v_o$, and the direction of the water's motion is normal to the outlet surface of the wheel, radial in radial flow, and axial in axial flow turbines.

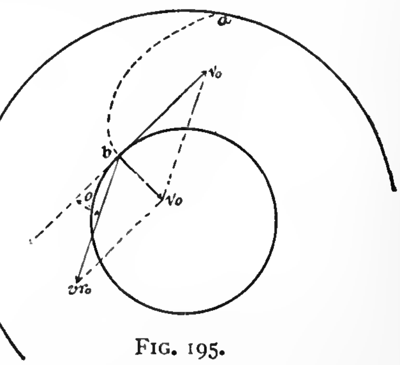

FIG. 195.

Drawing v_o or u_o radial or axial as the case may be, and V_o tangential to the direction of motion, v_{ro} can be found by the parallelogram of velocities. From fig. 195,

$$\tan\phi=v_o/V_o=u_o/V_o; \qquad (14)$$

but ϕ is the angle which the wheel vane makes with the outlet surface of the wheel, which is thus determined when the velocity of flow u_o and velocity of the wheel V_o are known. When ϕ is thus determined,

$$v_{ro}=u_o\operatorname{cosec}\phi=V_o\sqrt{(1+u_o^2/V_o^2)}. \qquad (14a)$$

Correction of the Angle ϕ to allow for Thickness of Vanes.—In determining ϕ, it is most convenient to calculate its value approximately at first, from a value of u_o obtained by neglecting the thickness of the vanes. As, however, this angle is the most important angle in the turbine, the value should be afterwards corrected to allow for the vane thickness.

Let

$$\phi'=\tan^{-1}(u_o/V_o)=\tan^{-1}(Q/\Omega_oV_o)$$

be the first or approximate value of ϕ, and let t be the thickness, and n the number of wheel vanes which reach the outlet surface of the wheel. As the vanes cut the outlet surface approximately at the angle ϕ', their width measured on that surface is $t\operatorname{cosec}\phi'$. Hence the space occupied by the vanes on the outlet surface is

$$\left.\begin{array}{l} \text{For A, fig. 192, } ntd_o\operatorname{cosec}\phi \\ \quad\text{B, fig. 192, } ntd\operatorname{cosec}\phi \\ \quad\text{C, fig. 192, } nt(r_2-r_1)\operatorname{cosec}\phi \end{array}\right\}. \qquad (15)$$

Call this area occupied by the vanes ω. Then the true value of the clear discharging outlet of the wheel is $\Omega_o-\omega$, and the true value of u_o is $Q/(\Omega_o-\omega)$. The corrected value of the angle of the vanes will be

$$\phi=\tan\,[Q/V_o(\Omega_o-\omega)]. \qquad (16)$$

§ 193. *Head producing Velocity with which the Water enters the Wheel.*—Consider the variation of pressure in a wheel passage, which satisfies the condition that the sections change so gradually that there is no loss of head in shock. When the flow is in a horizontal plane, there is no work done by gravity on the water passing through the wheel. In the case of an axial flow turbine, in which the flow is vertical, the fall d between the inlet and outlet surfaces should be taken into account.

Let V_i, V_o be the velocities of the wheel at the inlet and outlet surfaces,
v_i, v_o the velocities of the water,
u_i, u_o the velocities of flow,
v_{ri}, v_{ro} the relative velocities,
h_i, h_o the pressures, measured in feet of water,
r_i, r_o the radii of the wheel,
a the angular velocity of the wheel.

At any point in the path of a portion of water, at radius r, the velocity v of the water may be resolved into a component $V = ar$ equal to the velocity at that point of the wheel, and a relative component v_r. Hence the motion of the water may be considered to consist of two parts:—(a) a motion identical with that in a forced vortex of constant angular velocity a; (b) a flow along curves parallel to the wheel vane curves. Taking the latter first, and using Bernoulli's theorem, the change of pressure due to flow through the wheel passages is given by the equation

$$h'_i + v_{ri}^2/2g = h'_o + v_{ro}^2/2g;$$
$$h'_i - h'_o = (v_{ro}^2 - v_{ri}^2)/2g.$$

The variation of pressure due to rotation in a forced vortex is

$$h''_i - h''_o = (V_i^2 - V_o^2)/2g.$$

Consequently the whole difference of pressure at the inlet and outlet surfaces of the wheel is

$$h_i - h_o = h'_i + h''_i - h'_o - h''_o$$
$$= (V_i^2 - V_o^2)/2g + (v_{ro}^2 - v_{ri}^2)/2g. \qquad (17)$$

Case 1. *Axial Flow Turbines.*—$V_i = V_o$; and the first term on the right, in equation 17, disappears. Adding, however, the work of gravity due to a fall of d ft. in passing through the wheel,

$$h_i - h_o = (v_{ro}^2 - v_{ri}^2)/2g - d. \qquad (17a)$$

Case 2. *Outward Flow Turbines.*—The inlet radius is less than the outlet radius, and $(V_i^2 - V_o^2)/2g$ is negative. The centrifugal head diminishes the pressure at the inlet surface, and increases the velocity with which the water enters the wheel. This somewhat increases the frictional loss of head. Further, if the wheel varies in velocity from variations in the useful work done, the quantity $(V_i^2 - V_o^2)/2g$ increases when the turbine speed increases, and vice versa. Consequently the flow into the turbine increases when the speed increases, and diminishes when the speed diminishes, and this again augments the variation of speed. The action of the centrifugal head in an outward flow turbine is therefore prejudicial to steadiness of motion. For this reason $r_o : r_i$ is made small, generally about 5:4. Even then a governor is sometimes required to regulate the speed of the turbine.

Case 3. *Inward Flow Turbines.*—The inlet radius is greater than the outlet radius, and the centrifugal head diminishes the velocity of flow into the turbine. This tends to diminish the frictional losses, but it has a more important influence in securing steadiness of motion. Any increase of speed diminishes the flow into the turbine, and vice versa. Hence the variation of speed is less than the variation of resistance overcome. In the so-called centre vent wheels in America, the ratio $r_i : r_o$ is about 5:4, and then the influence of the centrifugal head is not very important. Professor James Thomson first pointed out the advantage of a much greater difference of radii. By making $r_i : r_o = 2:1$, the centrifugal head balances about half the head in the supply chamber. Then the velocity through the guide-blades does not exceed the velocity due to half the fall, and the action of the centrifugal head in securing steadiness of speed is considerable.

Since the total head producing flow through the turbine is $H - \mathfrak{h}$, and of this $h_i - h_o$ is expended in overcoming the pressure in the wheel, the velocity of flow into the wheel is

$$v_i = c_v \sqrt{\{2g(H - \mathfrak{h} - (V_i^2 - V_o^2/2g + (v_{ro}^2 - v_{ri}^2)/2g)\}}, \qquad (18)$$

where c_v may be taken 0·96.

From (14a),

$$v_{ro} = V_o \sqrt{(1 + u_o^2/V_o^2)}.$$

It will be shown immediately that

$$v_{ri} = u_i \operatorname{cosec} \theta;$$

or, as this is only a small term, and θ is on the average 90°, we may take, for the present purpose, $v_{ri} = u_i$ nearly.

Inserting these values, and remembering that for an axial flow turbine $V_i = V_o$, $\mathfrak{h} = 0$, and the fall d in the wheel is to be added,

$$v_i = c_v \sqrt{\left\{ 2g \left(H - \frac{V_i^2}{2g}\left(1 + \frac{u_o^2}{V_o^2}\right) + \frac{u_i^2}{2g} - d \right) \right\}}.$$

For an outward flow turbine,

$$v_i = c_v \sqrt{\left[2g \left\{ H - \mathfrak{h} - \frac{V_i^2}{2g}\left(1 + \frac{u_o^2}{V_i^2}\right) + \frac{u_i^2}{2g} \right\} \right]}.$$

For an inward flow turbine,

$$v_i = c_v \sqrt{\left[2g \left\{ H - \frac{V_i^2}{2g}\left(1 + \frac{u_o^2}{V_i^2}\right) + \frac{u_i^2}{2g} \right\} \right]}.$$

§ 194. *Angle which the Guide-Blades make with the Circumference of the Wheel.*—At the moment the water enters the wheel, the radial component of the velocity is u_i, and the velocity is v_i. Hence, if γ is the angle between the guide-blades and a tangent to the wheel

$$\gamma = \sin^{-1}(u_i/v_i).$$

This angle can, if necessary, be corrected to allow for the thickness of the guide-blades.

§ 195. *Condition determining the Angle of the Vanes at the Inlet Surface of the Wheel.*—The single condition necessary to be satisfied at the inlet surface of the wheel is that the water should enter the wheel without shock. This condition is satisfied if the direction of relative motion of the water and wheel is parallel to the first element of the wheel vanes.

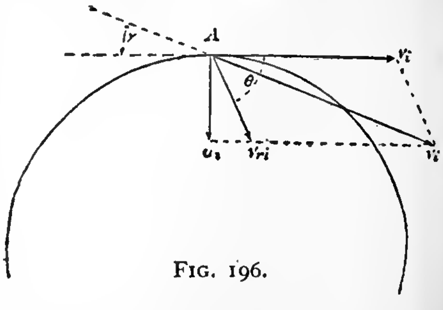

FIG. 196.

Let A (fig. 196) be a point on the inlet surface of the wheel, and let v_i represent in magnitude and direction the velocity of the water entering the wheel, and V_i the velocity of the wheel. Completing the parallelogram, v_{ri} is the direction of relative motion. Hence the angle between v_{ri} and V_i is the angle θ which the vanes should make with the inlet surface of the wheel.

§ 196. *Example of the Method of designing a Turbine. Professor James Thomson's Inward Flow Turbine.*—

Let H = the available fall after deducting loss of head in pipes and channels from the gross fall;
Q = the supply of water in cubic feet per second; and
η = the efficiency of the turbine.

The work done per second is ηGQH, and the horse-power of the turbine is $h.p. = \eta GQH/550$. If η is taken at 0·75, an allowance will be made for the frictional losses in the turbine, the leakage and the friction of the turbine shaft. Then $h.p. = 0{\cdot}085QH$.

The velocity of flow through the turbine (uncorrected for the space occupied by the vanes and guide-blades) may be taken

$$u_i = u_o = 0{\cdot}125\sqrt{2gH},$$

in which case about $\frac{1}{64}$th of the energy of the fall is carried away by the water discharged.

The areas of the outlet and inlet surface of the wheel are then

$$2\pi r_o d_o = 2\pi r_i d_i = Q/0{\cdot}125\sqrt{(2gH)}.$$

If we take r_o, so that the axial velocity of discharge from the central orifices of the wheel is equal to u_o, we get

$$r_o = 0{\cdot}3984\sqrt{(Q/\sqrt{H})},$$
$$d_o = r_o.$$

If, to obtain considerable steadying action of the centrifugal head, $r_i = 2r_o$, then $d_i = \frac{1}{2}d_o$.

Speed of the Wheel.—Let $V_i = 0{\cdot}66\sqrt{2gH}$, or the speed due to half the fall nearly. Then the number of rotations of the turbine per second is

$$N = V_i/2\pi r_i = 1{\cdot}0579\sqrt{(H\sqrt{H}/Q)};$$

also
$$V_o = V_i r_o/r_i = 0{\cdot}33\sqrt{2gH}.$$

Angle of Vanes with Outlet Surface.

$$\operatorname{Tan} \phi = u_o/V_o = 0{\cdot}125/0{\cdot}33 = {\cdot}3788;$$
$$\phi = 21° \text{ nearly}.$$

If this value is revised for the vane thickness it will ordinarily become about 25°.

Velocity with which the Water enters the Wheel.—The head producing the velocity is

$$H - (V_i^2/2g)(1 + u_o^2/V_i^2) + u_i^2/2g$$
$$= H\{1 - {\cdot}4356(1 + 0{\cdot}0358) + {\cdot}0156\}$$
$$= 0{\cdot}5646H.$$

Then the velocity is

$$V_i = {\cdot}96\sqrt{2g({\cdot}5646H)} = 0{\cdot}721\sqrt{2gH}.$$

Angle of Guide-Blades.

$$\operatorname{Sin} \gamma = u_i/v_i = 0{\cdot}125/0{\cdot}721 = 0{\cdot}173;$$
$$\gamma = 10° \text{ nearly}.$$

Tangential Velocity of Water entering Wheel.

$$w_i = v_i \cos \gamma = 0{\cdot}7101\sqrt{2gH}.$$

Angle of Vanes at Inlet Surface.

$$\operatorname{Cot} \theta = (w_i - V_i)/u_i = ({\cdot}7101 - {\cdot}66)/{\cdot}125 = {\cdot}4008;$$
$$\theta = 68° \text{ nearly}.$$

Hydraulic Efficiency of Wheel.

$$\eta = w_i V_i/gH = {\cdot}7101 \times {\cdot}66 \times 2$$
$$= 0{\cdot}9373.$$

This, however, neglects the friction of wheel covers and leakage. The efficiency from experiment has been found to be 0·75 to 0·80.

Impulse and Partial Admission Turbines.

§ 197. The principal defect of most turbines with complete admission is the imperfection of the arrangements for working with less than the normal supply. With many forms of reaction turbine the efficiency is considerably reduced when the regulating sluices are partially closed, but it is exactly when the supply of water is deficient that it is most important to get out of it the greatest possible amount of work. The imperfection of the regulating arrangements is therefore, from the practical point of view, a serious defect. All turbine makers have sought by various methods to improve the regulating mechanism. B. Fourneyron, by dividing his wheel by horizontal diaphragms, virtually obtained three or more separate radial flow turbines, which could be successively set in action at their full power, but the arrangement is not altogether successful, because of the spreading of the water in the space between the wheel and guide-blades. Fontaine similarly employed two concentric axial flow turbines formed in the same casing. One was worked at full power, the other regulated. By this arrangement the loss of efficiency due to the action of the regulating sluice affected only half the water power. Many makers have adopted the expedient of erecting two or three separate turbines on the same waterfall. Then one or more could be put out of action and the others worked at full power. All these methods are rather palliatives than remedies. The movable guide-blades of Professor James Thomson meet the difficulty directly, but they are not applicable to every form of turbine.

C. Callon, in 1840, patented an arrangement of sluices for axial or outward flow turbines, which were to be closed successively as the water supply diminished. By preference the sluices were closed by pairs, two diametrically opposite sluices forming a pair. The water was thus admitted to opposite but equal arcs of the wheel, and the forces driving the turbine were symmetrically placed. As soon as this arrangement was adopted,

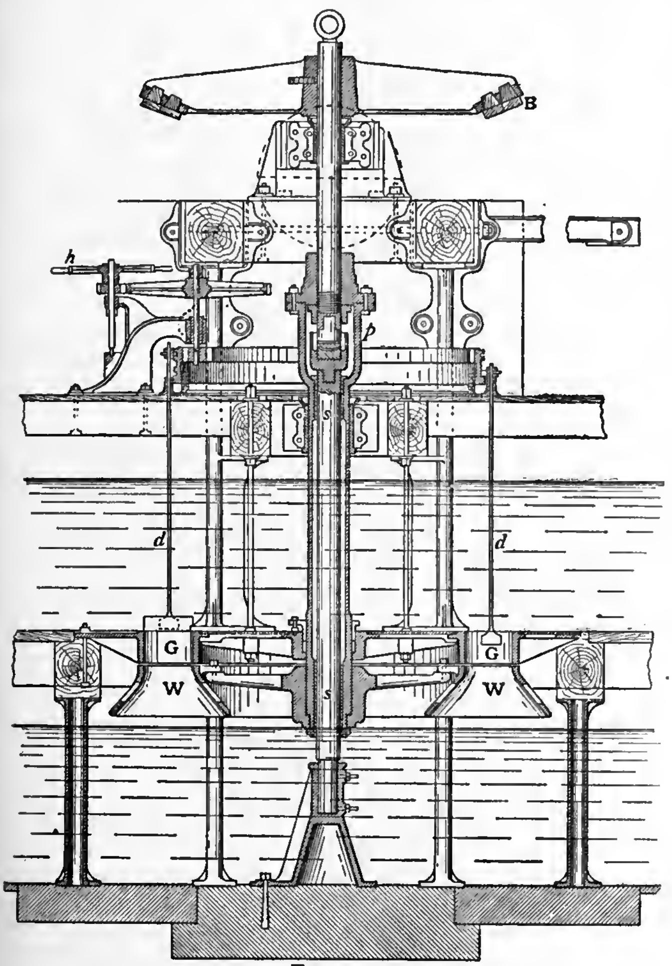

FIG. 197.

a modification of the mode of action of the water in the turbine became necessary. If the turbine wheel passages remain full of water during the whole rotation, the water contained in each passage must be put into motion each time it passes an open portion of the sluice, and stopped each time it passes a closed portion of the sluice. It is thus put into motion and stopped twice in each rotation. This gives rise to violent eddying motions and great loss of energy in shock. To prevent this, the turbine wheel with partial admission must be placed above the tail water, and the wheel passages be allowed to clear themselves of water, while passing from one open portion of the sluices to the next.

But if the wheel passages are free of water when they arrive at the open guide passages, then there can be no pressure other than atmospheric pressure in the clearance space between guides and wheel. The water must issue from the sluices with the whole velocity due to the head; received on the curved vanes of the wheel, the jets must be gradually deviated and discharged with a small final velocity only, precisely in the same way as when a single jet strikes a curved vane in the free air. Turbines of this kind are therefore termed turbines of free deviation. There is no variation of pressure in the jet during the whole time of its action on the wheel, and the whole energy of the jet is imparted to the wheel, simply by the impulse due to its gradual change of momentum. It is clear that the water may be admitted in exactly the same way to any fraction of the circumference at pleasure, without altering the efficiency of the wheel. The diameter of the wheel may be made as large as convenient, and the water admitted to a small fraction of the circumference only. Then the number of revolutions is independent of the water velocity, and may be kept down to a manageable value.

§ 198. *General Description of an Impulse Turbine or Turbine with Free Deviation.*—Fig. 197 shows a general sectional elevation of a Girard turbine, in which the flow is axial. The water, admitted above a horizontal floor, passes down through the annular wheel containing the guide-blades G, G, and thence into the revolving wheel WW. The revolving wheel is fixed to a hollow shaft suspended from the pivot *p*. The solid internal shaft *ss* is merely a fixed column supporting the pivot. The advantage of this is that the pivot is accessible for lubrication and adjustment. B is the mortise bevel wheel by which the power of the turbine is given off. The sluices are worked by the hand wheel *h*, which raises them successively, in a way to be described presently. *d*, *d* are the sluice rods. Figs. 198, 199 show the sectional form of the guide-blade chamber and wheel and the curves of the wheel vanes and guide-blades, when drawn on a plane development of the cylindrical section of the wheel; *a*, *a*, *a* are the sluices for cutting off the water; *b*, *b*, *b* are apertures by which the entrance or exit of air is facilitated as the buckets empty and fill. Figs. 200, 201 show the guide-blade gear. *a*, *a*, *a* are the sluice rods as before. At the top of each sluice rod is a small block *c*, having a projecting tongue, which slides in the groove of the circular cam plate *d*, *d*. This circular plate is supported on the frame *e*, and revolves on it by means of the flanged rollers *f*. Inside, at the top, the cam plate is toothed, and gears into a spur pinion connected with the hand wheel *h*. At *gg* is an inclined groove or shunt. When the tongues of the blocks *c*, *c* arrive at *g*, they slide up to a second groove, or the reverse, according as the cam plate is revolved in one direction or in the other. As this operation takes place with each

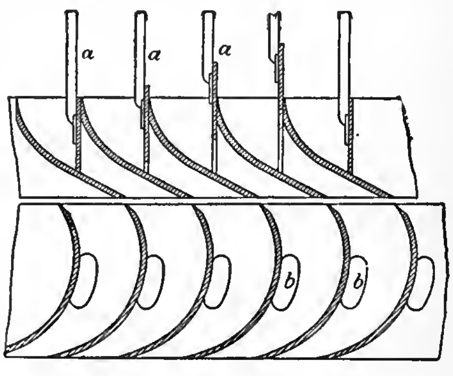

FIG. 198.

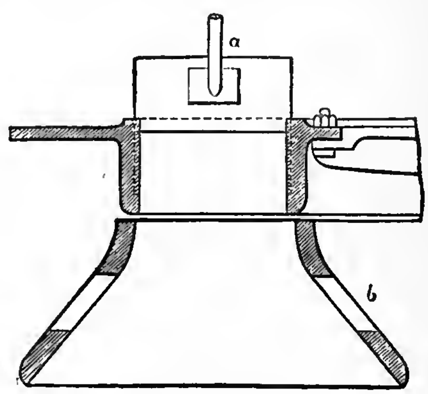

FIG. 199.

sluice successively, any number of sluices can be opened or closed as desired. The turbine is of 48 horse power on 5·12 ft. fall, and the supply of water varies from 35 to 112 cub. ft. per second. The

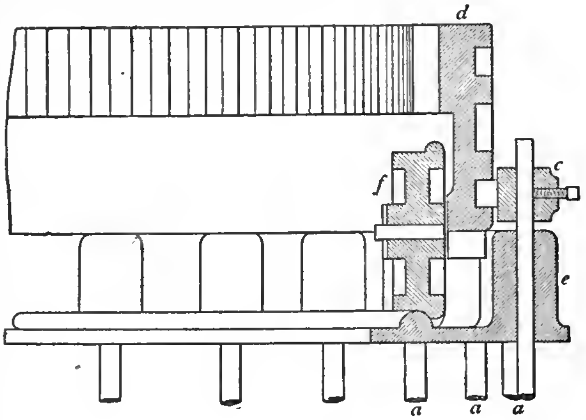

FIG. 200.

efficiency in normal working is given as 73%. The mean diameter of the wheel is 6 ft., and the speed 27·4 revolutions per minute.

As an example of a partial admission radial flow impulse turbine, a 100 h.p. turbine at Immenstadt may be taken. The fall varies from 538 to 570 ft. The external diameter of the wheel is $4\frac{1}{2}$ ft., and

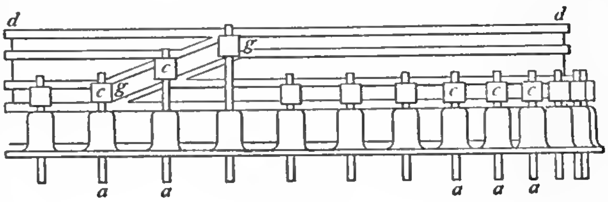

FIG. 201.

its internal diameter 3 ft. 10 in. Normal speed 400 revs. per minute. Water is discharged into the wheel by a single nozzle, shown in fig. 202 with its regulating apparatus and some of the vanes. The water enters the wheel at an angle of 22° with the direction of motion, and the final angle of the wheel vanes is 20°. The efficiency on trial was from 75 to 78%.

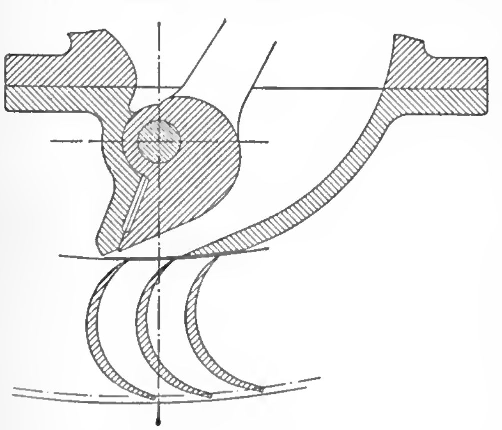

FIG. 202.

§ 199. *Theory of the Impulse Turbine.*—The theory of the impulse turbine does not essentially differ from that of the reaction turbine, except that there is no pressure in the wheel opposing the discharge from the guide-blades. Hence the velocity with which the water enters the wheel is simply

$$v_i = 0{\cdot}96\sqrt{2g(\mathrm{H}-\mathfrak{h})},$$

where $\mathfrak{h}$ is the height of the top of the wheel above the tail water. If the hydropneumatic system is used, then $\mathfrak{h}=0$. Let Q_m be the maximum supply of water, r_1, r_2 the internal and external radii of the wheel at the inlet surface; then

$$u_i = Q_m/\{\pi(r_2^2 - r_1^2)\}.$$

The value of u_i may be about $0{\cdot}45\sqrt{2g(\mathrm{H}-\mathfrak{h})}$, whence r_1, r_2 can be determined.

The guide-blade angle is then given by the equation

$$\sin\gamma = u_i/v_i = 0{\cdot}45/0{\cdot}94 = {\cdot}48;$$
$$\gamma = 29^\circ.$$

The value of u_i should, however, be corrected for the space occupied by the guide-blades.

The tangential velocity of the entering water is

$$w_i = v_i\cos\gamma = 0{\cdot}82\sqrt{2g(\mathrm{H}-\mathfrak{h})}.$$

The circumferential velocity of the wheel may be (at mean radius)

$$\mathrm{V}_i = 0{\cdot}5\sqrt{2g(\mathrm{H}-\mathfrak{h})}.$$

Hence the vane angle at inlet surface is given by the equation

$$\cot\theta = (w_i - \mathrm{V}_i)/u_i = (0{\cdot}82 - 0{\cdot}5)/0{\cdot}45 = {\cdot}71;$$
$$\theta = 55^\circ.$$

The relative velocity of the water striking the vane at the inlet edge is $v_{ri} = u_i \operatorname{cosec}\theta = 1{\cdot}22u_i$. This relative velocity remains unchanged during the passage of the water over the vane; consequently the relative velocity at the point of discharge is $v_{ro} = 1{\cdot}22u_i$. Also in an axial flow turbine $\mathrm{V}_o = \mathrm{V}_i$.

If the final velocity of the water is axial, then

$$\cos\phi = \mathrm{V}_o/v_{ro} = \mathrm{V}_i/v_{ri} = 0{\cdot}5/(1{\cdot}22\times0{\cdot}45) = \cos 24^\circ\ 23'.$$

This should be corrected for the vane thickness. Neglecting this, $u_o = v_{ro}\sin\phi = v_{ri}\sin\phi = u_i\operatorname{cosec}\theta\sin\phi = 0{\cdot}5u_i$. The discharging area of the wheel must therefore be greater than the inlet area in the ratio of at least 2 to 1. In some actual turbines the ratio is 7 to 3. This greater outlet area is obtained by splaying the wheel, as shown in the section (fig. 199).

§ 200. *Pelton Wheel.*—In the mining district of California about 1860 simple impulse wheels were used, termed hurdy-gurdy wheels. The wheels rotated in a vertical plane, being supported on a horizontal axis. Round the circumference were fixed flat vanes which were struck normally by a jet from a nozzle of size varying with the head and quantity of water. Such wheels have in fact long been used. They are not efficient, but they are very simply constructed. Then attempts were made to improve the efficiency, first by using hemispherical cup vanes, and then by using a double cup vane with a central dividing ridge, an arrangement invented by Pelton. In this last form the water from the nozzle passes half to each side of the wheel, just escaping clear of the backs of the advancing buckets. Fig. 203 shows a Pelton vane. Some small modifications have been made by other makers, but they are not of any great importance.

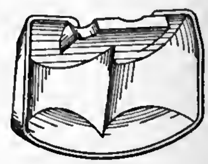

FIG. 203.

Fig. 204 shows a complete Pelton wheel with frame and casing, supply pipe and nozzle. Pelton wheels have been very largely used in America and to some extent in Europe. They are extremely simple and easy to construct or repair and on falls of 100 ft. or more are very efficient. The jet strikes tangentially to the mean radius of the buckets, and the face of the buckets is not quite radial but at right angles to the direction of the jet at the point of first impact. For greatest efficiency the peripheral velocity of the wheel at the mean radius of the buckets should be a little less than half the velocity of the jet. As the radius of the wheel can be taken arbitrarily, the number of revolutions per minute can be accommodated to that of the machinery to be driven. Pelton wheels have been made as small

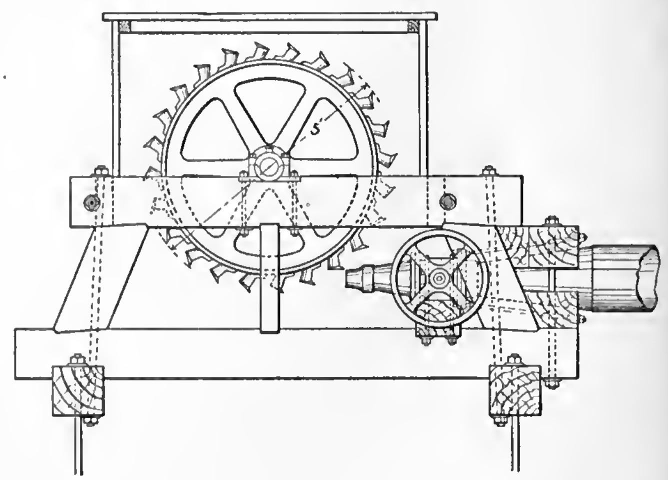

FIG. 204.

as 4 in. diameter, for driving sewing machines, and as large as 24 ft. The efficiency on high falls is about 80%. When large power is required two or three nozzles are used delivering on one wheel. The width of the buckets should be not less than seven times the diameter of the jet.

At the Comstock mines, Nevada, there is a 36-in. Pelton wheel made of a solid steel disk with phosphor bronze buckets riveted to the rim. The head is 2100 ft. and the wheel makes 1150 revolutions per minute, the peripheral velocity being 180 ft. per sec. With a $\frac{1}{2}$-in. nozzle the wheel uses 32 cub. ft. of water per minute and develops 100 h.p. At the Chollarshaft, Nevada, there are six Pelton wheels on a fall of 1680 ft. driving electrical generators. With $\frac{5}{8}$-in. nozzles each develops 125 h.p.

§ 201. *Theory of the Pelton Wheel.*—Suppose a jet with a velocity v strikes tangentially a curved vane AB (fig. 205) moving in the same direction with the velocity u. The water will flow over the vane with the relative velocity $v-u$ and at B will have the tangential relative velocity $v-u$ making an angle α with the direction of the vane's motion. Combining this with the velocity u of the vane, the absolute velocity of the water leaving the vane will be $w=\mathrm{B}c$. The component of w in the direction of motion of the vane is $\mathrm{B}a=\mathrm{B}b-ab=u-(v-u)\cos\alpha$. Hence if Q is the quantity of water reaching the vane per second the change of momentum per second in the direction of the vane's motion is $(\mathrm{GQ}/g)[v-\{u-(v-u)\cos\alpha\}]=(\mathrm{GQ}/g)(v-u)(1+\cos\alpha)$. If $\alpha=0°$, $\cos\alpha=1$, and the change of momentum per second, which is equal to the effort driving the vane, is $\mathrm{P}=2(\mathrm{GQ}/g)(v-u)$. The work done on the vane is $\mathrm{P}u=2(\mathrm{GQ}/g)(v-u)u$. If a series of vanes are interposed in succession, the quantity of water impinging on the vanes per second is the total discharge of the nozzle, and the energy expended at the nozzle is $\mathrm{GQ}v^2/2g$. Hence the efficiency of the arrangement is, when $\alpha=0°$, neglecting friction,

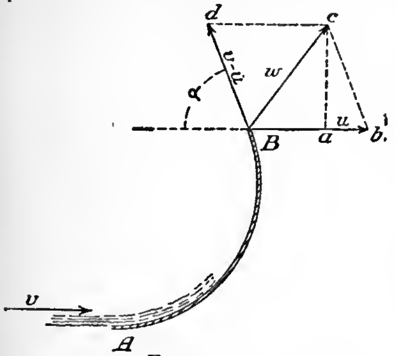

FIG. 205.

$$\eta=2\mathrm{P}u/\mathrm{GQ}v^2=4(v-u)u/v^2,$$

which is a maximum and equal to unity if $u=\frac{1}{2}v$. In that case the whole energy of the jet is usefully expended in driving the series of vanes. In practice α cannot be quite zero or the water leaving one vane would strike the back of the next advancing vane. Fig. 203 shows a Pelton vane. The water divides each way, and leaves the vane on each side in a direction nearly parallel to the direction of motion of the vane. The best velocity of the vane is very approximately half the velocity of the jet.

§ 202. *Regulation of the Pelton Wheel.*—At first Pelton wheels were adjusted to varying loads merely by throttling the supply. This method involves a total loss of part of the head at the sluice or throttle valve. In addition as the working head is reduced, the relation between wheel velocity and jet velocity is no longer that of greatest efficiency. Next a plan was adopted of deflecting the jet so that only part of the water reached the wheel when the load was reduced, the rest going to waste. This involved the use of an equal quantity of water for large and small loads, but it had, what in some cases is an advantage, the effect of preventing any water hammer in the supply pipe due to the action of the regulator. In most cases now regulation is effected by varying the section of the jet. A conical needle in the nozzle can be advanced or withdrawn so as to occupy more or less of the aperture of the nozzle. Such a needle can be controlled by an ordinary governor.

§ 203. *General Considerations on the Choice of a Type of Turbine.*—The circumferential speed of any turbine is necessarily a fraction of the initial velocity of the water, and therefore is greater as the head is greater. In reaction turbines with complete admission the number of revolutions per minute becomes inconveniently great, for the diameter cannot be increased beyond certain limits without greatly reducing the efficiency. In impulse turbines with partial admission the diameter can be chosen arbitrarily and the number of revolutions kept down on high falls to any desired amount. Hence broadly reaction turbines are better and less costly on low falls, and impulse turbines on high falls. For variable water flow impulse turbines have some advantage, being more efficiently regulated. On the other hand, impulse turbines lose efficiency seriously if their speed varies from the normal speed due to the head. If the head is very variable, as it often is on low falls, and the turbine must run at the same speed whatever the head, the impulse turbine is not suitable. Reaction turbines can be constructed so as to overcome this difficulty to a great extent. Axial flow turbines with vertical shafts have the disadvantage that in addition to the weight of the turbine there is an unbalanced water pressure to be carried by the footstep or collar bearing. In radial flow turbines the hydraulic pressures are balanced. The application of turbines to drive dynamos directly has involved some new conditions. The electrical engineer generally desires a high speed of rotation, and a very constant speed at all times. The reaction turbine is generally more suitable than the impulse turbine. As the diameter of the turbine depends on the quantity of water and cannot be much varied without great inefficiency, a difficulty arises on low falls. This has been met by constructing four independent reaction turbines on the same shaft, each having of course the diameter suitable for one-quarter of the whole discharge, and having a higher speed of rotation than a larger turbine. The turbines at Rheinfelden and Chevres are so constructed. To ensure constant speed of rotation when the head varies considerably without serious inefficiency, an axial flow turbine is generally used. It is constructed of three or four concentric rings of vanes, with independent regulating sluices, forming practically independent turbines of different radii. Any one of these or any combination can be used according to the state of the water. With a high fall the turbine of largest radius only is used, and the speed of rotation is less than with a turbine of smaller radius. On the other hand, as the fall decreases the inner turbines are used either singly or together, according to the power required. At the Zürich waterworks there are turbines of 90 h.p. on a fall varying from $10\frac{1}{2}$ ft. to $4\frac{3}{4}$ ft. The power and speed are kept constant. Each turbine has three concentric rings. The outermost ring gives 90 h.p. with 105 cub. ft. per second and the maximum fall. The outer and middle compartments give the same power with 140 cub. ft. per second and a fall of 7 ft. 10 in. All three compartments working together develop the power with about 250 cub. ft. per second. In some tests the efficiency was 74% with the outer ring working alone, 75·4% with the outer and middle ring working and a fall of 7 ft., and 80·7% with all the rings working.

§ 204. *Speed Governing.*—When turbines are used to drive dynamos direct, the question of speed regulation is of great importance. Steam engines using a light elastic fluid can be easily regulated by governors acting on throttle or expansion valves. It is different with water turbines using a fluid of great inertia.

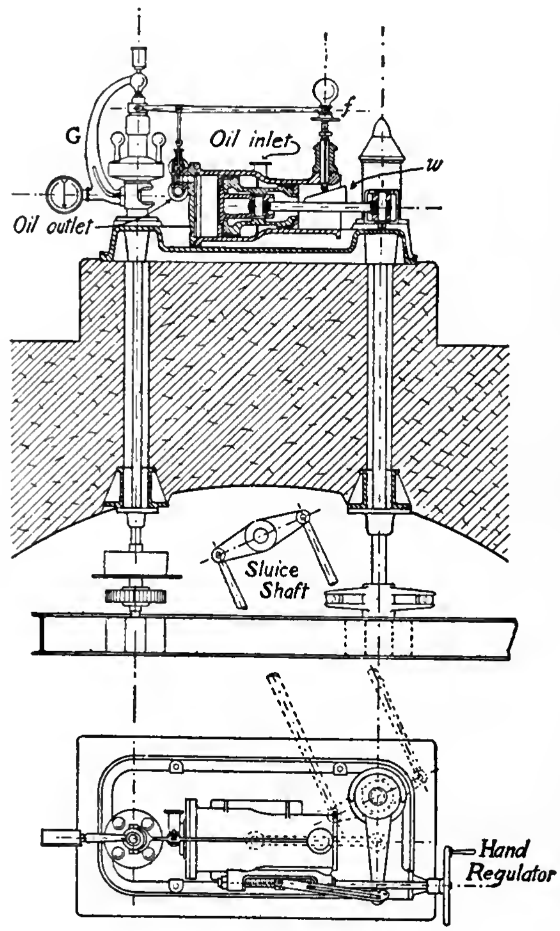

FIG. 206.

In one of the Niagara penstocks there are 400 tons of water flowing at 10 ft. per second, opposing enormous resistance to rapid change of speed of flow. The sluices of water turbines also are necessarily large and heavy. Hence relay governors must be used, and the tendency of relay governors to hunt must be overcome. In the Niagara Falls Power House No. 1, each turbine has a very sensitive centrifugal governor acting on a ratchet relay. The governor puts into gear one or other of two ratchets driven by the turbine itself. According as one or the other ratchet is in gear the sluices are raised or lowered. By a subsidiary arrangement the ratchets are gradually put out of gear unless the governor puts them in gear again, and this prevents the over correction of the speed from the lag in the action of the governor. In the Niagara Power House No. 2, the relay is an hydraulic relay similar in principle, but rather more complicated in arrangement, to that shown in fig. 206, which is a governor used for the 1250 h.p. turbines at Lyons. The sensitive governor G opens a valve and puts into action a plunger driven by oil pressure from an oil reservoir. As the plunger moves forward it gradually closes the oil admission valve by lowering the fulcrum end *f* of the valve lever which rests on a wedge *w* attached to the plunger. If the speed is still too high, the governor reopens the valve. In the case of the Niagara turbines the oil pressure is 1200 ℔ per sq. in. One millimetre of movement of the governor sleeve completely opens the relay valve, and the relay plunger exerts a force of 50 tons. The sluices can be completely opened or shut in twelve seconds. The ordinary variation of speed of the turbine with varying load does not exceed 1%. If all the load is thrown off, the momentary variation of speed is not more than 5%. To prevent hydraulic shock in the supply pipes, a relief valve is provided which opens if the pressure is in excess of that due to the head.

§ 205. *The Hydraulic Ram.*—The hydraulic ram is an arrangement by which a quantity of water falling a distance h forces a portion of the water to rise to a height h_1, greater than h. It consists of a supply reservoir (A, fig. 207), into which the water enters from some natural stream. A pipe *s* of considerable length conducts the water to a lower level, where it is discharged intermittently through a self-acting pulsating valve at *d*. The supply pipe *s* may be fitted with a flap valve for stopping the ram, and this is attached in some cases to a float, so that the ram starts and stops itself automatically, according as the supply cistern fills or empties. The lower float is just sufficient to keep open the flap after it has been raised by the action of the upper float. The length of chain is adjusted so that the upper float opens the flap when the level in the cistern is at the desired height. If the water-level falls below the lower float the flap closes. The pipe *s* should be as long and as straight as possible, and as it is subjected to considerable pressure from the sudden arrest of the motion of the water, it must be strong and strongly jointed. *a* is an air vessel, and *e* the delivery pipe leading to the reservoir at a higher level than A, into which water is to be pumped. Fig. 208 shows in section the construction of the ram itself. *d* is the pulsating discharge valve already mentioned, which opens inwards and downwards. The stroke of the valve is regulated by the cotter through the spindle, under which are washers by which the amount of fall can be regulated. At *o* is a delivery valve, opening outwards, which is often a ball-valve but sometimes a flap-valve. The water which is pumped passes through this valve into the air vessel *a*, from which it flows by the delivery pipe in a regular stream into the cistern to which the water is to be raised. In the vertical chamber behind the outer valve a small air vessel is formed, and into this opens an aperture $\frac{1}{4}$ in. in diameter, made in a brass screw plug *b*. The hole is reduced to $\frac{1}{16}$ in. in diameter at the outer end of the plug and is closed by a small valve opening inwards. Through this, during the rebound after each stroke of the ram, a small quantity of air is sucked in which keeps the air vessel supplied with its elastic cushion of air.

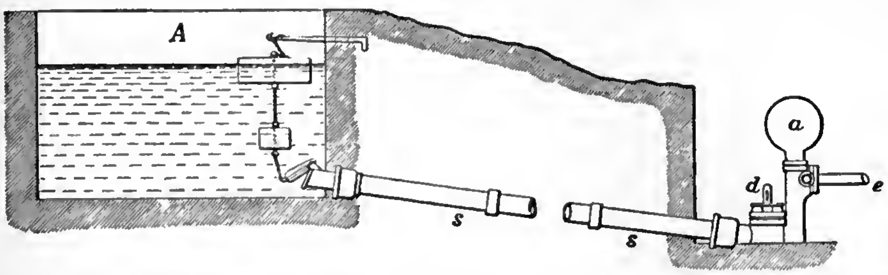

FIG. 207.

During the recoil after a sudden closing of the valve *d*, the pressure below it is diminished and the valve opens, permitting outflow. In consequence of the flow through this valve, the water in the supply pipe acquires a gradually increasing velocity. The upward flow of the water, towards the valve *d*, increases the pressure tending to lift the valve, and at last, if the valve is not too heavy, lifts and closes it. The forward momentum of the column in the supply pipe being destroyed by the stoppage of the flow, the water exerts a pressure at the end of the pipe sufficient to open the delivery valve *o*, and to cause a portion of the water to flow into the air vessel. As the water in the supply pipe comes to rest and recoils, the valve *d* opens again and the operation is repeated. Part of the energy of the descending column is employed in compressing the air at the end of the supply pipe and expanding the pipe itself. This causes a recoil of the water which momentarily diminishes the pressure in the pipe below the pressure due to the statical head. This assists in opening the valve *d*. The recoil of the water is sufficiently great to enable a pump to be attached to the ram body instead of the direct rising pipe. With this arrangement a ram working with muddy water may be employed to raise clear spring water. Instead of lifting the delivery valve as in the ordinary ram, the momentum of the column drives a sliding or elastic piston, and the recoil brings it back. This piston lifts and forces alternately the clear water through ordinary pump valves.

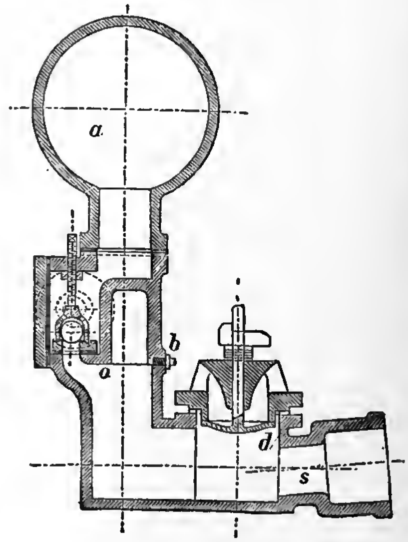

FIG. 208.

PUMPS

§ 206. The different classes of pumps correspond almost exactly to the different classes of water motors, although the mechanical details of the construction are somewhat different. They are properly reversed water motors. Ordinary reciprocating pumps correspond to water-pressure engines. Chain and bucket pumps are in principle similar to water wheels in which the water acts by weight. Scoop wheels are similar to undershot water wheels, and centrifugal pumps to turbines.

Reciprocating Pumps are single or double acting, and differ from water-pressure engines in that the valves are moved by the water instead of by automatic machinery. They may be classed thus:—

1. *Lift Pumps.*—The water drawn through a foot valve on the ascent of the pump bucket is forced through the bucket valve when it descends, and lifted by the bucket when it reascends. Such pumps give an intermittent discharge.

2. *Plunger* or *Force Pumps*, in which the water drawn through the foot valve is displaced by the descent of a solid plunger, and forced through a delivery valve. They have the advantage that

the friction is less than that of lift pumps, and the packing round the plunger is easily accessible, whilst that round a lift pump bucket is not. The flow is intermittent.

3. *The Double-acting Force Pump* is in principle a double plunger pump. The discharge fluctuates from zero to a maximum and back to zero each stroke, but is not arrested for any appreciable time.

4. *Bucket and Plunger Pumps* consist of a lift pump bucket combined with a plunger of half its area. The flow varies as in a double-acting pump.

5. *Diaphragm Pumps* have been used, in which the solid plunger is replaced by an elastic diaphragm, alternately depressed into and raised out of a cylinder.

As single-acting pumps give an intermittent discharge three are generally used on cranks at 120°. But with all pumps the variation of velocity of discharge would cause great waste of work in the delivery pipes when they are long, and even danger from the hydraulic ramming action of the long column of water. An air vessel is interposed between the pump and the delivery pipes, of a volume from 5 to 100 times the space described by the plunger per stroke. The air in this must be replenished from time to time, or continuously, by a special air-pump. At low speeds not exceeding 30 ft. per minute the delivery of a pump is about 90 to 95% of the volume described by the plunger or bucket, from 5 to 10% of the discharge being lost by leakage. At high speeds the quantity pumped occasionally exceeds the volume described by the plunger, the momentum of the water keeping the valves open after the turn of the stroke.

The velocity of large mining pumps is about 140 ft. per minute, the indoor or suction stroke being sometimes made at 250 ft. per minute. Rotative pumping engines of large size have a plunger speed of 90 ft. per minute. Small rotative pumps are run faster, but at some loss of efficiency. Fire-engine pumps have a speed of 180 to 220 ft. per minute.

The efficiency of reciprocating pumps varies very greatly. Small reciprocating pumps, with metal valves on lifts of 15 ft., were found by Morin to have an efficiency of 16 to 40%, or on the average 25%. When used to pump water at considerable pressure, through hose pipes, the efficiency rose to from 28 to 57%, or on the average, with 50 to 100 ft. of lift, about 50%. A large pump with barrels 18 in. diameter, at speeds under 60 ft. per minute, gave the following results:—

Lift in feet . . .	$14\frac{1}{2}$	34	47
Efficiency	·46	·66	·70

The very large steam-pumps employed for waterworks, with 150 ft. or more of lift, appear to reach an efficiency of 90%, not including the friction of the discharge pipes. Reckoned on the indicated work of the steam-engine the efficiency may be 80%.

Many small pumps are now driven electrically and are usually three-throw single-acting pumps driven from the electric motor by gearing. It is not convenient to vary the speed of the motor to accommodate it to the varying rate of pumping usually required. Messrs Hayward Tyler have introduced a mechanism for varying the stroke of the pumps (Sinclair's patent) from full stroke to nil, without stopping the pumps.

§ 207. *Centrifugal Pump.*—For large volumes of water on lifts not exceeding about 60 ft. the most convenient pump is the centrifugal pump. Recent improvements have made it available also for very high lifts. It consists of a wheel or fan with curved vanes enclosed in an annular chamber. Water flows in at the centre and is discharged at the periphery. The fan may rotate in a vertical or horizontal plane and the water may enter on one or both sides of the fan. In the latter case there is no axial unbalanced pressure. The fan and its casing must be filled with water before it can start, so that if not drowned there must be a foot valve on the suction pipe. When no special attention needs to be paid to efficiency the water may have a velocity of 6 to 7 ft. in the suction and delivery pipes. The fan often has 6 to 12 vanes. For a double-inlet fan of diameter D, the diameter of the inlets is D/2. If Q is the discharge in cub. ft. per second $D =$ about $0{\cdot}6\sqrt{Q}$ in average cases. The peripheral speed is a little greater than the velocity due to the lift. Ordinary centrifugal pumps will have an efficiency of 40 to 60%.

The first pump of this kind which attracted notice was one exhibited by J. G. Appold in 1851, and the special features of his pump have been retained in the best pumps since constructed. Appold's pump raised continuously a volume of water equal to 1400 times its own capacity per minute. It had no valves, and it permitted the passage of solid bodies, such as walnuts and oranges, without obstruction to its working. Its efficiency was also found to be good.

Fig. 209 shows the ordinary form of a centrifugal pump. The pump disk and vanes B are cast in one, usually of bronze,

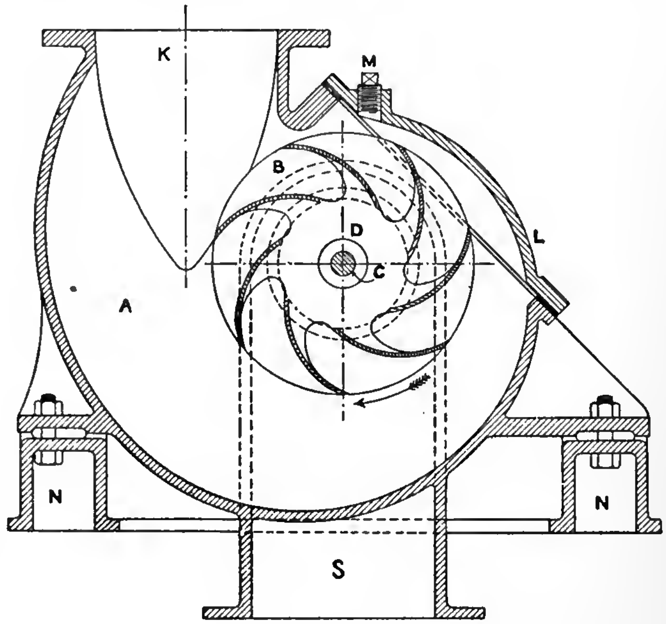

FIG. 209.

and the disk is keyed on the driving shaft C. The casing A has a spirally enlarging discharge passage into the discharge pipe K. A cover L gives access to the pump. S is the suction pipe which opens into the pump disk on both sides at D.

Fig. 210 shows a centrifugal pump differing from ordinary centrifugal pumps in one feature only. The water rises through a suction pipe S, which divides so as to enter the pump wheel W at the centre on each side. The pump disk or wheel is very similar to a turbine wheel. It is keyed on a shaft driven by a belt on a fast and loose pulley arrangement at P. The water rotating in the pump disk presses outwards, and if the speed is sufficient a continuous flow is maintained through the pump and into the discharge pipe D. The special feature in this pump is that the water, discharged by the pump disk with a whirling velocity of not inconsiderable magnitude, is allowed to continue rotation in a chamber somewhat larger than the pump. The use of this whirlpool chamber was first suggested by Professor James Thomson. It utilizes the energy due to the whirling velocity of the water which in most pumps is wasted in eddies in the discharge pipe. In the pump shown guide-blades are also added which have the direction of the stream lines in a free vortex. They do not therefore interfere with the action of the water when pumping the normal quantity, but only prevent irregular motion. At A is a plug by which the pump case is filled before starting. If the pump is above the water to be pumped, a foot valve is required to permit the pump to be filled. Sometimes instead of the foot valve a delivery valve is used, an air-pump or steam jet pump being employed to exhaust the air from the pump case.

§ 208. *Design and Proportions of a Centrifugal Pump.*—The design of the pump disk is very simple. Let r_i, r_o be the radii of the inlet and outlet surfaces of the pump disk, d_i, d_o the clear axial width at those radii. The velocity of flow through the pump may be taken

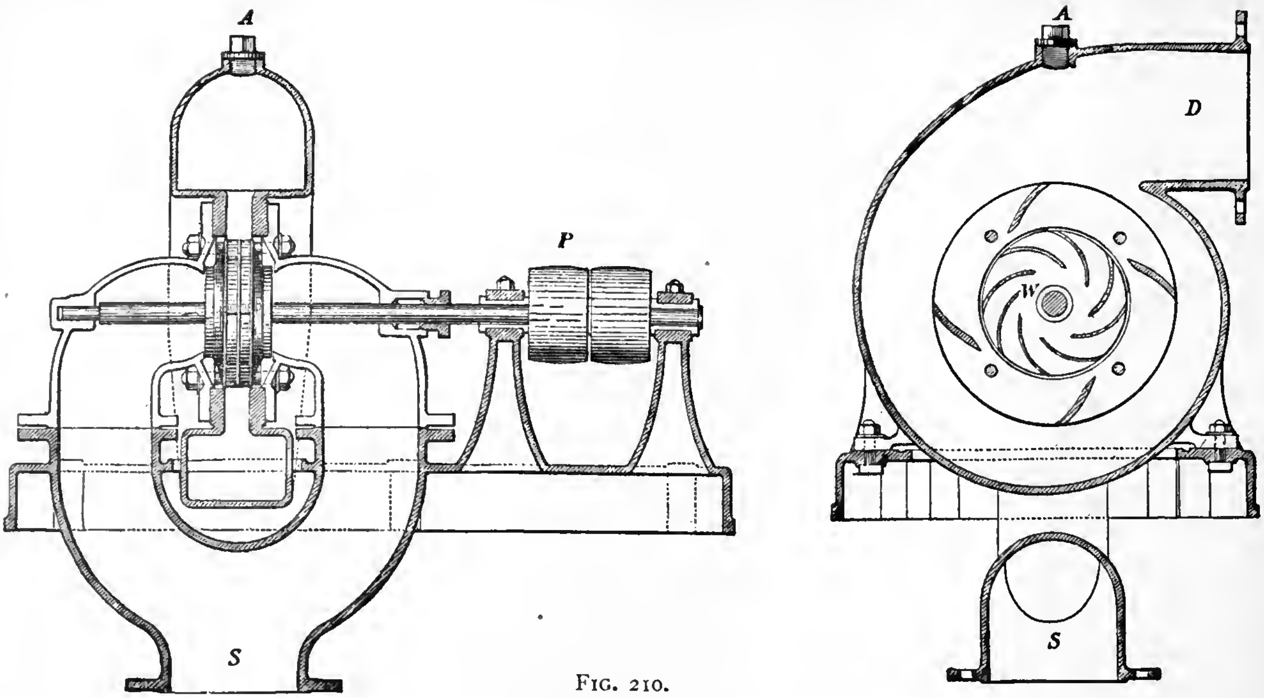

FIG. 210.

the same as for a turbine. If Q is the quantity pumped, and H the lift,

$$u_i = 0{\cdot}25\sqrt{2gH}. \qquad (1)$$
$$2\pi r_i d_i = Q/u_i.$$

Also in practice

$$\left.\begin{aligned} d_i &= 1{\cdot}2r_i \ \ldots \\ r_i &= {\cdot}2571\sqrt{(Q/\sqrt{H})}. \end{aligned}\right\} \qquad (2)$$

Hence,

Usually $r_o = 2r_i$,
and $d_o = d_i$ or $\frac{1}{2}d_i$

according as the disk is parallel-sided or coned. The water enters the wheel radially with the velocity u_i, and

$$u_o = Q/2\pi r_o d_o. \qquad (3)$$

Fig. 211 shows the notation adopted for the velocities. Suppose the water enters the wheel with the velocity v_i, while the velocity of the wheel is V_i. Completing the parallelogram, v_{ri} is the relative velocity of the water and wheel, and is the proper direction of the wheel vanes. Also, by resolving, u_i and w_i are the component velocities of flow and velocities of whir of the velocity v_i of the water. At the outlet surface, v_o is the final velocity of discharge, and the rest of the notation is similar to that for the inlet surface.

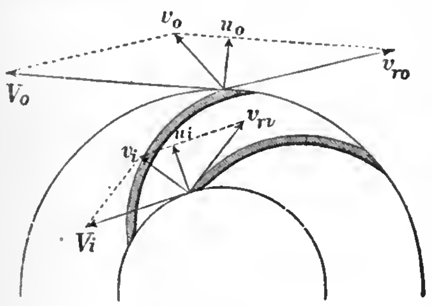

FIG. 211.

Usually the water flows equally in all directions in the eye of the wheel, in that case v_i is radial. Then, in normal conditions of working, at the inlet surface,

$$\left.\begin{aligned} v_i &= u_i \\ w_i &= 0 \\ \tan\theta &= u_i/V_i \\ v_{ri} &= u_i \operatorname{cosec}\theta = \sqrt{(u_i^2+V_i^2)} \end{aligned}\right\} \qquad (4)$$

If the pump is raising less or more than its proper quantity, θ will not satisfy the last condition, and there is then some loss of head in shock.

At the outer circumference of the wheel or outlet surface,

$$\left.\begin{aligned} v_{ro} &= u_o \operatorname{cosec}\phi \\ w_o &= V_o - u_o \cot\phi \\ v_o &= \sqrt{\{u_o^2 + (V_o - u_o \cot\phi)^2\}} \end{aligned}\right\} \qquad (5)$$

Variation of Pressure in the Pump Disk.—Precisely as in the case of turbines, it can be shown that the variation of pressure between the inlet and outlet surfaces of the pump is

$$h_o - h_i = (V_o^2 - V_i^2)/2g - (v_{ro}^2 - v_{ri}^2)/2g.$$

Inserting the values of v_{ro}, v_{ri} in (4) and (5), we get for normal conditions of working

$$\begin{aligned} h_o - h_i &= (V_o^2 - V_i^2)/2g - u_o^2 \operatorname{cosec}^2\phi/2g + (u_i^2 + V_i^2)/2g \\ &= V_o^2/2g - u_o^2 \operatorname{cosec}^2\phi/2g + u_i^2/2g. \end{aligned} \qquad (6)$$

Hydraulic Efficiency of the Pump.—Neglecting disk friction, journal friction, and leakage, the efficiency of the pump can be found in the same way as that of turbines (§ 186). Let M be the moment of the couple rotating the pump, and a its angular velocity; w_o, r_o the tangential velocity of the water and radius at the outlet surface; w_i, r_i the same quantities at the inlet surface. Q being the discharge per second, the change of angular momentum per second is

$$(GQ/g)(w_o r_o - w_i r_i).$$

Hence $\qquad M = (GQ/g)(w_o r_o - w_i r_i).$

In normal working, $w_i = 0$. Also, multiplying by the angular velocity, the work done per second is

$$Ma = (GQ/g) w_o r_o a.$$

But the useful work done in pumping is GQH. Therefore the efficiency is

$$\eta = GQH/Ma = gH/w_o r_o a = gH/w_o V_o. \qquad (7)$$

§ 209. Case 1. *Centrifugal Pump with no Whirlpool Chamber.*—When no special provision is made to utilize the energy of motion of the water leaving the wheel, and the pump discharges directly into a chamber in which the water is flowing to the discharge pipe, nearly the whole of the energy of the water leaving the disk is wasted. The water leaves the disk with the more or less considerable velocity v_o, and impinges on a mass flowing to the discharge pipe at the much slower velocity v_s. The radial component of v_o is almost necessarily wasted. From the tangential component there is a gain of pressure

$$\begin{aligned} (w_o^2 - v_s^2)/2g &- (w_o - v_s)^2/2g \\ &= v_s(w_o - v_s)/g, \end{aligned}$$

which will be small, if v_s is small compared with w_o. Its greatest value, if $v_s = \frac{1}{2}w_o$, is $\frac{1}{4}w_o^2/2g$, which will always be a small part of the whole head. Suppose this neglected. The whole variation of pressure in the pump disk then balances the lift and the head $u_i^2/2g$ necessary to give the initial velocity of flow in the eye of the wheel.

$$u_i^2/2g + H = V_o^2/2g - u_o^2 \operatorname{cosec}^2\phi/2g + u_i^2/2g,$$

$$\left.\begin{aligned} H &= V_o^2/2g - u_o^2 \operatorname{cosec}^2\phi/2g \\ V_o &= \sqrt{(2gH + u_o^2 \operatorname{cosec}^2\phi} \ .\end{aligned}\right\} \qquad (8)$$

or

and the efficiency of the pump is, from (7),

$$\begin{aligned} \eta &= gH/V_o w_o = gH/\{V(V_o - n_o \cot\phi)\}, \\ &= (V_o^2 - u_o^2 \operatorname{cosec}^2\phi)/\{2V_o(V_o - u_o \cot\phi\}, \end{aligned} \qquad (9)$$

For $\phi = 90°$, $\qquad \eta = (V_o^2 - u_o^2)/2V_o^2,$

which is necessarily less than $\frac{1}{2}$. That is, half the work expended in driving the pump is wasted. By recurving the vanes, a plan introduced by Appold, the efficiency is increased, because the velocity v_o of discharge from the pump is diminished. If ϕ is very small,

$$\operatorname{cosec}\phi = \cot\phi;$$

and then $\qquad \eta = (V_o + u_o \operatorname{cosec}\phi)/2V_o,$

which may approach the value 1, as ϕ tends towards 0. Equation (8) shows that $u_o \operatorname{cosec}\phi$ cannot be greater than V_o. Putting $u_o = 0{\cdot}25\sqrt{(2gH)}$ we get the following numerical values of the efficiency and the circumferential velocity of the pump:—

ϕ	η	V_o
90°	0·47	$1{\cdot}03\sqrt{2gH}$
45°	0·56	1·06 ,,
30°	0·65	1·12 ,,
20°	0·73	1·24 ,,
10°	0·84	1·75 ,,

ϕ cannot practically be made less than 20°; and, allowing for the frictional losses neglected, the efficiency of a pump in which $\phi=20°$ is found to be about ·60.

§ 210. Case 2. *Pump with a Whirlpool Chamber*, as in fig. 210.—Professor James Thomson first suggested that the energy of the water after leaving the pump disk might be utilized, if a space were left in which a free vortex could be formed. In such a free vortex the velocity varies inversely as the radius. The gain of pressure in the vortex chamber is, putting r_o, r_w for the radii to the outlet surface of wheel and to outside of free vortex,

$$\frac{v_o^2}{2g}\left(1-\frac{r_o^2}{r_w^2}\right)=\frac{v_o^2}{2g}\left(1-k^2\right),$$

if $k=r_o/r_w$.

The lift is then, adding this to the lift in the last case,

$$H=\{V_o^2-u_o^2\operatorname{cosec}^2\phi+v_o^2(1-k^2)\}/2g.$$

But $v_o^2=V_o^2-2V_ou_o\cot\phi+u_o^2\operatorname{cosec}^2\phi$;

$$\therefore H=\{(2-k^2)V_o^2-2kV_ou_o\cot\phi-k^2u_o^2\operatorname{cosec}^2\phi\}/2g. \qquad (10)$$

Putting this in the expression for the efficiency, we find a considerable increase of efficiency. Thus with

$\phi=90°$ and $k=\frac{1}{2}$, $\eta=\frac{7}{8}$ nearly,
ϕ a small angle and $k=\frac{1}{2}$, $\eta=1$ nearly.

With this arrangement of pump, therefore, the angle at the outer ends of the vanes is of comparatively little importance. A moderate angle of 30° or 40° may very well be adopted. The following numerical values of the velocity of the circumference of the pump have been obtained by taking $k=\frac{1}{2}$, and $u_o=0{\cdot}25\sqrt{(2gH)}$.

ϕ	V_o
90°	$\cdot762\sqrt{2gH}$
45°	·842 ,,
30°	·911 ,,
20°	1·023 ,,

The quantity of water to be pumped by a centrifugal pump necessarily varies, and an adjustment for different quantities of water cannot easily be introduced. Hence it is that the average efficiency of pumps of this kind is in practice less than the efficiencies given above. The advantage of a vortex chamber is also generally neglected. The velocity in the supply and discharge pipes is also often made greater than is consistent with a high degree of efficiency. Velocities of 6 or 7 ft. per second in the discharge and suction pipes, when the lift is small, cause a very sensible waste of energy; 3 to 6 ft. would be much better. Centrifugal pumps of very large size have been constructed. Easton and Anderson made pumps for the North Sea canal in Holland to deliver each 670 tons of water per minute on a lift of 5 ft. The pump disks are 8 ft. diameter. J. and H. Gwynne constructed some pumps for draining the Ferrarese Marshes, which together deliver 2000 tons per minute. A pump made under Professor J. Thomson's direction for drainage works in Barbados had a pump disk 16 ft. in diameter and a whirlpool chamber 32 ft. in diameter. The efficiency of centrifugal pumps when delivering less or more than the normal quantity of water is discussed in a paper in the *Proc. Inst. Civ. Eng.* vol. 53.

§ 211. *High Lift Centrifugal Pumps.*—It has long been known that centrifugal pumps could be worked in series, each pump overcoming a part of the lift. This method has been perfected, and centrifugal pumps for very high lifts with great efficiency have been used by Sulzer and others. C. W. Darley (*Proc. Inst. Civ. Eng.*, supplement to vol. 154, p. 156) has described some pumps of this new type driven by Parsons steam turbines for the water supply of Sydney, N.S.W. Each pump was designed to deliver $1\frac{1}{2}$ million gallons per twenty-four hours against a head of 240 ft. at 3300 revs. per minute. Three pumps in series give therefore a lift of 720 ft. The pump consists of a central double-sided impeller 12 in. diameter. The water entering at the bottom divides and enters the runner at each side through a bell-mouthed passage. The shaft is provided with ring and groove glands which on the suction side keep the air out and on the pressure side prevent leakage. Some water from the pressure side leaks through the glands, but beyond the first grooves it passes into a pocket and is returned to the suction side of the pump. For the glands on the suction side water is supplied from a low-pressure service. No packing is used in the glands. During the trials no water was seen at the glands. The following are the results of tests made at Newcastle:—

	I.	II.	III.	IV.
Duration of test . . . hours	2	1·54	1·2	1·55
Steam pressure lb per sq. in.	57	57	84	55
Weight of steam per water h.p. hour . . . . . lb	27·93	30·67	28·83	27·89
Speed in revs. per min. . .	3300	3330	3710	3340
Height of suction . . . ft.	11	11	11	11
Total lift . . . . . . ft.	762	744	917	756
Million galls. per day pumped—				
By Venturi meter . . .	1·573	1·499	1·689	1·503
By orifice	1·623	1·513	1·723	1·555
Water h.p.	252	235	326	239

In trial IV. the steam was superheated 95° F. From other trials under the same conditions as trial I. the Parsons turbine uses 15·6 lb of steam per brake h.p. hour, so that the combined efficiency of turbine and pumps is about 56%, a remarkably good result.

§ 212. *Air-Lift Pumps.*—An interesting and simple method of pumping by compressed air, invented by Dr J. Pohlé of Arizona, is likely to be very useful in certain cases. Suppose a rising main placed in a deep bore hole in which there is a considerable depth of water. Air compressed to a sufficient pressure is conveyed by an air pipe and introduced at the lower end of the rising main. The air rising in the main diminishes the average density of the contents of the main, and their aggregate weight no longer balances the pressure at the lower end of the main due to its submersion. An upward flow is set up, and if the air supply is sufficient the water in the rising main is lifted to any required height. The higher the lift above the level in the bore hole the deeper must be the point at which air is injected. Fig. 212 shows an air-lift pump constructed for W. H. Maxwell at the Tunbridge Wells waterworks. There is a two-stage steam air compressor, compressing air to from 90 to 100 lb per sq. in. The bore hole is 350 ft. deep, lined with steel pipes 15 in. diameter for 200 ft. and with perforated pipes $13\frac{1}{2}$ in. diameter for the lower 150 ft. The rest level of the water is 96 ft. from the ground-level, and the level when pumping 32,000 gallons per hour is 120 ft. from the ground-level. The rising main is 7 in. diameter, and is carried nearly to the bottom of the bore hole and to 20 ft. above the ground-level. The air pipe is $2\frac{1}{2}$ in. diameter. In a trial run 31,402 gallons per hour were raised 133 ft. above the level in the well. Trials of the efficiency of the system made at San Francisco with varying conditions will be found in a paper by E. A. Rix (*Journ. Amer. Assoc. Eng. Soc.* vol. 25,

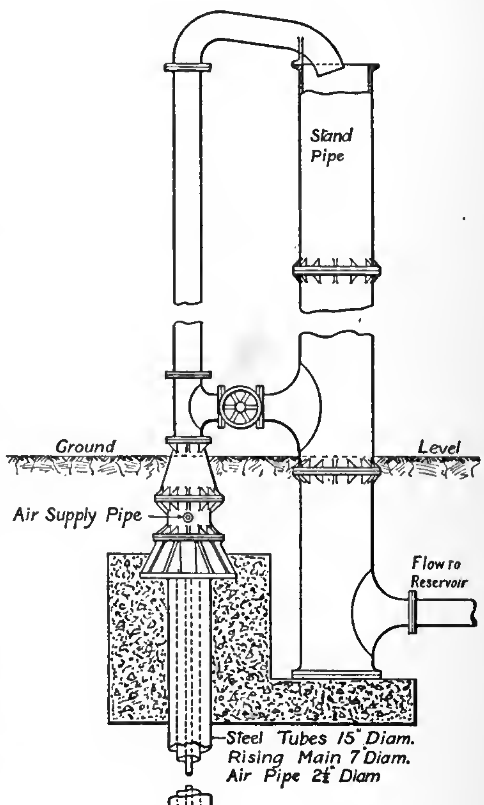

Fig. 212.

1900). Maxwell found the best results when the ratio of immersion to lift was 3 to 1 at the start and 2·2 to 1 at the end of the trial. In these conditions the efficiency was 37% calculated on the indicated h.p. of the steam-engine, and 46% calculated on the indicated work of the compressor. 2·7 volumes of free air were used to 1 of water lifted. The system is suitable for temporary purposes, especially as the quantity of water raised is much greater than could be pumped by any other system in a bore hole of a given size. It is useful for clearing a boring of sand and may be advantageously used permanently when a boring is in sand or gravel which cannot be kept out of the bore hole. The initial cost is small.

§ 213. *Centrifugal Fans.*—Centrifugal fans are constructed similarly to centrifugal pumps, and are used for compressing air to pressures not exceeding 10 to 15 in. of water-column. With this small variation of pressure the variation of volume and density of the air may be neglected without sensible error. The conditions of pressure and discharge for fans are generally less accurately known than in the case of pumps, and the design of fans is generally somewhat crude. They seldom have whirlpool chambers, though a large expanding outlet is provided in the case of the important Guibal fans used in mine ventilation.

It is usual to reckon the difference of pressure at the inlet and outlet of a fan in inches of water-column. One inch of water-column = 64·4 ft. of air at average atmospheric pressure = 5·2 lb per sq. ft.

Roughly the pressure-head produced in a fan without means of utilizing the kinetic energy of discharge would be $v^2/2g$ ft. of air, or $0{\cdot}00024\,v^2$ in. of water, where v is the velocity of the tips of the fan blades in feet per second. If d is the diameter of the fan and t the width at the external circumference, then πdt is the discharge area of the fan disk. If Q is the discharge in cub. ft. per sec., $u = Q/\pi dt$ is the radial velocity of discharge which is numerically equal to the discharge per square foot of outlet in cubic feet per second. As both the losses in the fan and the work done are roughly proportional to u^2 in fans of the same type, and are also proportional to the gauge pressure p, then if the losses are to be a constant percentage of the work done u may be taken proportional to $\sqrt{p}$. In ordinary cases u = about $22\sqrt{p}$. The width t of the fan is generally from 0·35 to $0{\cdot}45d$. Hence if Q is given, the diameter of the fan should be:—

For $t = 0{\cdot}35d$, $\quad d = 0{\cdot}20\sqrt{(Q/\sqrt{p})}$
For $t = 0{\cdot}45d$, $\quad d = 0{\cdot}18\sqrt{(Q/\sqrt{p})}$

If p is the pressure difference in the fan in inches of water, and N the revolutions of fan,

$v = \pi d N/60$ ft. per sec.
$N = 1230\sqrt{p}/d$ revs. per min.

As the pressure difference is small, the work done in compressing the air is almost exactly $5{\cdot}2pQ$ foot-pounds per second. Usually, however, the kinetic energy of the air in the discharge pipe is not inconsiderable compared with the work done in compression. If w is the velocity of the air where the discharge pressure is measured, the air carries away $w^2/2g$ foot-pounds per lb of air as kinetic energy. In Q cubic feet or 0·0807Q lb the kinetic energy is $0{\cdot}00125\,Qw^2$ foot-pounds per second.

The efficiency of fans is reckoned in two ways. If B.H.P. is the effective horse-power applied at the fan shaft, then the efficiency reckoned on the work of compression is

$$\eta = 5{\cdot}2pQ/550\text{B.H.P.}$$

On the other hand, if the kinetic energy in the delivery pipe is taken as part of the useful work the efficiency is

$$\eta_2 = (5{\cdot}2pQ + 0{\cdot}00125Qw^2)/550\text{B.H.P.}$$

Although the theory above is a rough one it agrees sufficiently with experiment, with some merely numerical modifications.

An extremely interesting experimental investigation of the action of centrifugal fans has been made by H. Heenan and W. Gilbert (*Proc. Inst. Civ. Eng.* vol. 123, p. 272). The fans delivered through an air trunk in which different resistances could be obtained by introducing diaphragms with circular apertures of different sizes. Suppose a fan run at constant speed with different resistances and the compression pressure, discharge and brake horse-power measured. The results plot in such a diagram as is shown in fig. 213. The less the resistance to discharge, that is the larger the opening in the air trunk, the greater the quantity of air discharged at the given speed of the fan. On the other hand the compression pressure diminishes. The curve marked total gauge is the compression pressure + the velocity head in the discharge pipe, both in inches of water. This curve falls, but not nearly so much as the compression curve, when the resistance in the air trunk is diminished. The brake horse-power increases as the resistance is diminished because the volume of discharge increases very much. The curve marked efficiency is the efficiency calculated on the work of compression only. It is zero for no discharge, and zero also when there is no resistance and all the energy given to the air is carried away as kinetic energy. There is a discharge for which this efficiency is a maximum; it is about half the discharge which there is when there is no resistance and the delivery pipe is full open. The conditions of speed and discharge corresponding to the greatest efficiency of compression are those ordinarily taken as the best normal conditions of working. The curve marked

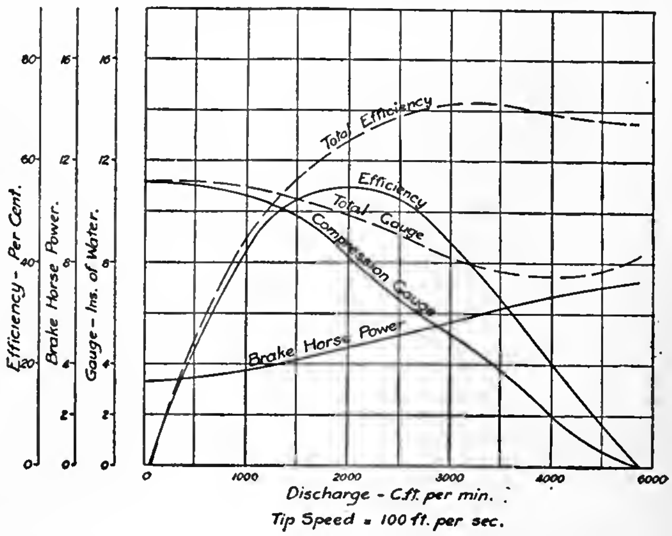

FIG. 213.

total efficiency gives the efficiency calculated on the work of compression and kinetic energy of discharge. Messrs Gilbert and Heenan found the efficiencies of ordinary fans calculated on the compression to be 40 to 60% when working at about normal conditions.

Taking some of Messrs Heenan and Gilbert's results for ordinary fans in normal conditions, they have been found to agree fairly with the following approximate rules. Let p_c be the compression pressure and q the volume discharged per second per square foot of outlet area of fan. Then the total gauge pressure due to pressure of compression and velocity of discharge is approximately: $p = p_c + 0{\cdot}0004q^2$ in. of water, so that if p_c is given, p can be found approximately. The pressure p depends on the circumferential speed v of the fan disk—

$p = 0{\cdot}00025v^2$ in. of water
$v = 63\sqrt{p}$ ft. per sec.

The discharge per square foot of outlet of fan is—

$q = 15$ to $18\sqrt{p}$ cub. ft. per sec.

The total discharge is

$Q = \pi dtq = 47$ to $56\,dt\sqrt{p}$
For $\quad t = {\cdot}35d$, $\quad d = 0{\cdot}22$ to $0{\cdot}25\sqrt{(Q/\sqrt{p})}$ ft.
$t = {\cdot}45d$, $\quad d = 0{\cdot}20$ to $0{\cdot}22\sqrt{(Q/\sqrt{p})}$ ft.
$N = 1203\sqrt{p}/d$.

These approximate equations, which are derived purely from experiment, do not differ greatly from those obtained by the rough theory given above. The theory helps to explain the reason for the form of the empirical results. (W. C. U.)

HYDRAZINE (DIAMIDOGEN), N_2H_4 or $H_2N{\cdot}NH_2$, a compound of hydrogen and nitrogen, first prepared by Th. Curtius in 1887 from diazo-acetic ester, $N_2CH{\cdot}CO_2C_2H_5$. This ester, which is obtained by the action of potassium nitrate on the hydrochloride of amidoacetic ester, yields on hydrolysis with hot concentrated potassium hydroxide an acid, which Curtius regarded as $C_3H_3N_6(CO_2H)_3$, but which A. Hantzsch and O. Silberrad (*Ber.*, 1900, 33, p. 58) showed to be $C_2H_2N_4(CO_2H)_2$, bisdiazo-acetic acid. On digestion of its warm aqueous solution with warm dilute sulphuric acid, hydrazine sulphate and oxalic acid are obtained. C. A. Lobry de Bruyn (*Ber.*, 1895, 28, p. 3085) prepared free hydrazine by dissolving its hydrochloride in methyl alcohol and adding sodium methylate; sodium chloride was precipitated and the residual liquid afterwards fractionated under reduced pressure. It can also be prepared by reducing potassium dinitrososulphonate in ice cold water by means of sodium amalgam:—

$$\begin{matrix}KSO_3\\KO\end{matrix}\!\!>N{\cdot}NO \rightarrow \begin{matrix}KSO_3\\H\end{matrix}\!\!>N{\cdot}NH_2 \rightarrow K_2SO_4 + N_2H_4.$$

P. J. Schestakov (*J. Russ. Phys. Chem. Soc.*, 1905, 37, p. 1) obtained hydrazine by oxidizing urea with sodium hypochlorite in the presence of benzaldehyde, which, by combining with the hydrazine, protected it from oxidation. F. Raschig (German Patent 198307, 1908) obtained good yields by oxidizing ammonia with sodium hypochlorite in solutions made viscous with glue. Free hydrazine is a colourless liquid which boils at 113·5° C., and solidifies about 0° C. to colourless crystals; it is heavier than water, in which it dissolves with rise of temperature. It is rapidly oxidized on exposure, is a strong reducing agent, and reacts vigorously with the halogens. Under certain conditions it may be oxidized to azoimide (A. W. Browne and F. F. Shetterly, *J. Amer. C.S.*, 1908, p. 53). By fractional distillation of its aqueous solution hydrazine hydrate $N_2H_4 \cdot H_2O$ (or perhaps $H_2N \cdot NH_3OH$), a strong base, is obtained, which precipitates the metals from solutions of copper and silver salts at ordinary temperatures. It dissociates completely in a vacuum at 143°, and when heated under atmospheric pressure to 183° it decomposes into ammonia and nitrogen (A. Scott, *J. Chem. Soc.*, 1904, 85, p. 913). The sulphate $N_2H_4 \cdot H_2SO_4$, crystallizes in tables which are slightly soluble in cold water and readily soluble in hot water; it is decomposed by heating above 250° C. with explosive evolution of gas and liberation of sulphur. By the addition of barium chloride to the sulphate, a solution of the hydrochloride is obtained, from which the crystallized salt may be obtained on evaporation.

Many organic derivatives of hydrazine are known, the most important being phenylhydrazine, which was discovered by Emil Fischer in 1877. It can be best prepared by V. Meyer and Lecco's method (*Ber.*, 1883, 16, p. 2976), which consists in reducing phenyldiazonium chloride in concentrated hydrochloric acid solution with stannous chloride also dissolved in concentrated hydrochloric acid. Phenylhydrazine is liberated from the hydrochloride so obtained by adding sodium hydroxide, the solution being then extracted with ether, the ether distilled off, and the residual oil purified by distillation under reduced pressure. Another method is due to E. Bamberger. The diazonium chloride, by the addition of an alkaline sulphite, is converted into a diazosulphonate, which is then reduced by zinc dust and acetic acid to phenylhydrazine potassium sulphite. This salt is then hydrolysed by heating it with hydrochloric acid—

$$C_6H_5N_2Cl + K_2SO_3 = KCl + C_6H_5N_2 \cdot SO_3K,$$
$$C_6H_5N_2 \cdot SO_3K + 2H = C_6H_5 \cdot NH \cdot NH \cdot SO_3K,$$
$$C_6H_5NH \cdot NH \cdot SO_3K + HCl + H_2O = C_6H_5 \cdot NH \cdot NH_2 \cdot HCl + KHSO_4.$$

Phenylhydrazine is a colourless oily liquid which turns brown on exposure. It boils at 241° C., and melts at 17·5° C. It is slightly soluble in water, and is strongly basic, forming well-defined salts with acids. For the detection of substances containing the carbonyl group (such for example as aldehydes and ketones) phenylhydrazine is a very important reagent, since it combines with them with elimination of water and the formation of well-defined *hydrazones* (see ALDEHYDES, KETONES and SUGARS). It is a strong reducing agent; it precipitates cuprous oxide when heated with Fehling's solution, nitrogen and benzene being formed at the same time—$C_6H_5 \cdot NH \cdot NH_2 + 2CuO = Cu_2O + N_2 + H_2O + C_6H_6$. By energetic reduction of phenylhydrazine (*e.g.* by use of zinc dust and hydrochloric acid), ammonia and aniline are produced—$C_6H_5NH \cdot NH_2 + 2H = C_6H_5NH_2 + NH_3$. It is also a most important synthetic reagent. It combines with aceto-acetic ester to form phenylmethylpyrazolone, from which antipyrine (*q.v.*) may be obtained. Indoles (*q.v.*) are formed by heating certain hydrazones with anhydrous zinc chloride; while semicarbazides, pyrrols (*q.v.*) and many other types of organic compounds may be synthesized by the use of suitable phenylhydrazine derivatives.

HYDRAZONE, in chemistry, a compound formed by the condensation of a hydrazine with a carbonyl group (see ALDEHYDES; KETONES).

HYDROCARBON, in chemistry, a compound of carbon and hydrogen. Many occur in nature in the free state: for example, natural gas, petroleum and paraffin are entirely composed of such bodies; other natural sources are india-rubber, turpentine and certain essential oils. They are also revealed by the spectroscope in stars, comets and the sun. Of artificial productions the most fruitful and important is provided by the destructive or dry distillation of many organic substances; familiar examples are the distillation of coal, which yields ordinary lighting gas, composed of gaseous hydrocarbons, and also coal tar, which, on subsequent fractional distillations, yields many liquid and solid hydrocarbons, all of high industrial value. For details reference should be made to the articles wherein the above subjects are treated. From the chemical point of view the hydrocarbons are of fundamental importance, and, on account of their great number, and still greater number of derivatives, they are studied as a separate branch of the science, namely, organic chemistry.

See CHEMISTRY for an account of their classification, &c.

HYDROCELE (Gr. ὕδωρ, water, and κήλη, tumour), the medical term for any collection of fluid other than pus or blood in the neighbourhood of the testis or cord. The fluid is usually serous. Hydrocele may be congenital or arise in the middle-aged without apparent cause, but it is usually associated with chronic orchitis or with tertiary syphilitic enlargements. The hydrocele appears as a rounded, fluctuating translucent swelling in the scrotum, and when greatly distended causes a dragging pain. Palliative treatment consists in tapping aseptically and removing the fluid, the patient afterwards wearing a suspender. The condition frequently recurs and necessitates radical treatment. Various substances may be injected; or the hydrocele is incised, the tunica partly removed and the cavity drained.

HYDROCEPHALUS (Gr. ὕδωρ, water, and κεφαλή, head), a term applied to disease of the brain which is attended with excessive effusion of fluid into its cavities. It exists in two forms—*acute* and *chronic hydrocephalus*. Acute hydrocephalus is another name for tuberculous meningitis (see MENINGITIS).

Chronic hydrocephalus, or "water on the brain," consists in an effusion of fluid into the lateral ventricles of the brain. It is not preceded by tuberculous deposit or acute inflammation, but depends upon congenital malformation or upon chronic inflammatory changes affecting the membranes. When the disease is congenital, its presence in the foetus is apt to be a source of difficulty in parturition. It is however more commonly developed in the first six months of life; but it occasionally arises in older children, or even in adults. The chief symptom is the gradual increase in size of the upper part of the head out of all proportion to the face or the rest of the body. Occurring at an age when as yet the bones of the skull have not become welded together, the enlargement may go on to an enormous extent, the spaces between the bones becoming more and more expanded. In a well-marked case the deformity is very striking; the upper part of the forehead projects abnormally, and the orbital plates of the frontal bone being inclined forwards give a downward tilt to the eyes, which have also peculiar rolling movements. The face is small, and this, with the enlarged head, gives a remarkable aged expression to the child. The body is ill-nourished, the bones are thin, the hair is scanty and fine and the teeth carious or absent.

The average circumference of the adult head is 22 in., and in the normal child it is of course much less. In chronic hydrocephalus the head of an infant three months old has measured 29 in.; and in the case of the man Cardinal, who died in Guy's Hospital, the head measured 33 in. In such cases the head cannot be supported by the neck, and the patient has to keep mostly in the recumbent posture. The expansibility of the skull prevents destructive pressure on the brain, yet this organ is materially affected by the presence of the fluid. The cerebral ventricles are distended, and the convolutions are flattened. Occasionally the fluid escapes into the cavity of the cranium, which it fills, pressing down the brain to the base of the skull. As a consequence, the functions of the brain are interfered with, and the mental condition is impaired. The child is dull, listless and irritable, and sometimes imbecile. The special senses become affected as the disease advances; sight is often lost, as is also hearing. Hydrocephalic children generally sink in a few years; nevertheless there have been instances of persons with this disease living to old age. There are, of course, grades of the affection, and children may present many of the symptoms of it in a slight degree, and yet recover, the head ceasing to expand, and becoming in due course firmly ossified.

Various methods of treatment have been employed, but the results are unsatisfactory. Compression of the head by bandages, and the administration of mercury with the view of promoting absorption of the fluid, are now little resorted to. Tapping the fluid from time to time through one of the spaces between the bones, drawing off a little, and thereafter employing gentle pressure, has been tried, but rarely with benefit. Attempts have also been made to establish a permanent drainage between the interior of the lateral ventricle and the sub-dural space, and between the lumbar region of the spine and the abdomen, but without satisfactory results. On the whole, the plan of treatment which aims at maintaining the patient's nutrition by appropriate food and tonics is the most rational and successful. (E. O.*)

HYDROCHARIDEAE, in botany, a natural order of Monocotyledons, belonging to the series Helobieae. They are water-plants, represented in Britain by frog-bit (*Hydrocharis Morsus-ranae*) and water-soldier (*Stratiotes aloïdes*). The order contains about fifty species in fifteen genera, twelve of which occur in fresh water while three are marine: and includes both floating and submerged forms. *Hydrocharis* floats on the surface of still water, and has rosettes of kidney-shaped leaves, from among which spring the flower-stalks; stolons bearing new leaf-rosettes are sent out on all sides, the plant thus propagating itself in the same way as the strawberry. *Stratiotes aloïdes* has a rosette of stiff sword-like leaves, which when the plant is in flower project above the surface; it is also stoloniferous, the young rosettes sinking to the bottom at the beginning of winter and rising again to the surface in the spring. *Vallisneria* (eel-grass) contains two species, one native of tropical Asia, the other inhabiting the warmer parts of both hemispheres and reaching as far north as south Europe. It grows in the mud at the bottom of fresh water, and the short stem bears a cluster of long, narrow grass-like leaves; new plants are formed at the end of horizontal runners. Another type is represented by *Elodea canadensis* or water-thyme, which has been introduced into the British Isles from North America. It is a small, submerged plant with long, slender branching stems bearing whorls of narrow toothed leaves; the flowers appear at the surface when mature. *Halophila*, *Enhalus* and *Thalassia* are submerged maritime plants found on tropical coasts, mainly in the Indian and Pacific oceans; *Halophila* has an elongated stem rooting at the nodes; *Enhalus* a short, thick rhizome, clothed with black threads resembling horse-hair, the persistent hard-bast strands of the leaves; *Thalassia* has a creeping rooting stem with upright branches bearing crowded strap-shaped leaves in two rows. The flowers spring from, or are enclosed in, a spathe, and are unisexual and regular, with generally a calyx and corolla, each of three members; the stamens are in whorls of three, the inner whorls are often barren; the two to fifteen carpels form an inferior ovary containing generally numerous ovules on often large, produced, parietal placentas. The fruit is leathery or fleshy, opening irregularly. The seeds contain a large embryo and no endosperm. In *Hydrocharis* (fig. 1), which is dioecious, the flowers are borne above the surface of the water, have conspicuous white petals, contain honey and are pollinated by insects. *Stratiotes* has similar flowers which come above the surface only for pollination, becoming submerged again during ripening of the fruit. In *Vallisneria* (fig. 2), which is also dioecious, the small male flowers are borne in large numbers in short-stalked spathes; the petals are minute and scale-like, and only two of the three stamens are fertile; the flowers become detached before opening and rise to the surface, where the sepals expand and form a float bearing the two projecting semi-erect stamens. The female flowers are solitary and are raised to the surface on a long, spiral stalk; the ovary bears three broad styles, on which some of the large, sticky pollen-grains from the floating male flowers get deposited (fig. 3). After pollination the female flower becomes drawn below the surface by the spiral contraction of the long stalk, and the fruit ripens near the bottom. *Elodea* has polygamous flowers (that is, male, female and hermaphrodite), solitary, in slender, tubular spathes; the male flowers become detached and rise to the surface; the females are raised to the surface when mature, and receive the floating pollen from the male. The flowers of *Halophila* are submerged and apetalous.

The order is a widely distributed one; the marine forms are tropical or subtropical, but the fresh-water genera occur also in the temperate zones.

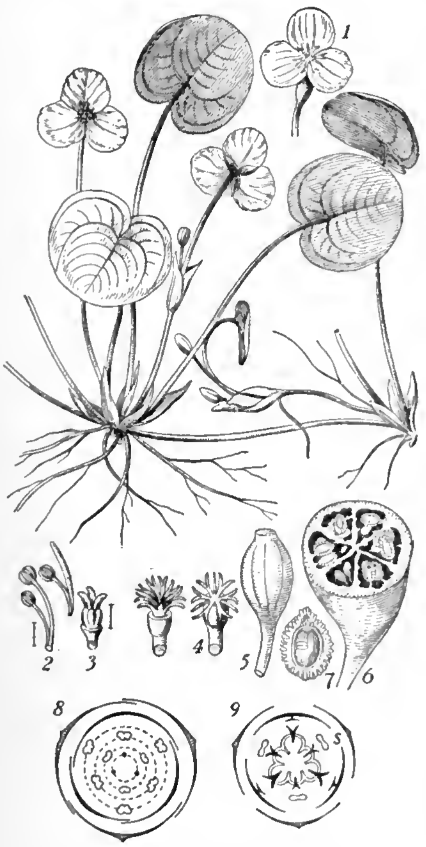

FIG. 1.—*Hydrocharis Morsus-ranae*—Frog-bit—male plant, half natural size.
1, Female flower, half natural size.
2, Stamens, enlarged.
3, Barren pistil of male flower, enlarged.
4, Pistil of female flower.

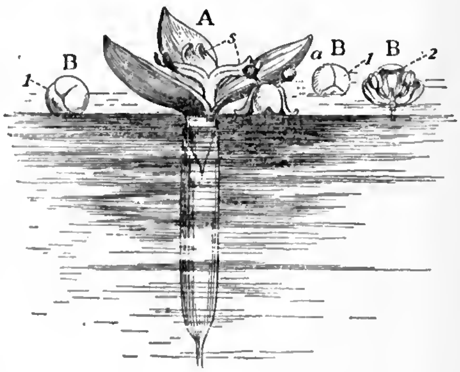

FIG. 3.

HYDROCHLORIC ACID, also known in commerce as "spirits of salts" and "muriatic acid," a compound of hydrogen and chlorine. Its chemistry is discussed under CHLORINE, and its manufacture under ALKALI MANUFACTURE.

HYDRODYNAMICS (Gr. ὕδωρ, water, δύναμις, strength), the branch of hydromechanics which discusses the motion of fluids (see HYDROMECHANICS).

HYDROGEN [symbol H, atomic weight 1·008 (o=16)], one of the chemical elements. Its name is derived from Gr. ὕδωρ, water, and γεννάειν, to produce, in allusion to the fact that water is produced when the gas burns in air. Hydrogen appears to have been recognized by Paracelsus in the 16th century; the combustibility of the gas was noticed by Turquet de Mayenne in the 17th century, whilst in 1700 N. Lemery showed that a mixture of hydrogen and air detonated on the application of a light. The first definite experiments concerning the nature of hydrogen were made in 1766 by H. Cavendish, who showed that it was formed when various metals were acted upon by dilute sulphuric or hydrochloric acids. Cavendish called it "inflammable air," and for some time it was confused with other inflammable gases, all of which were supposed to contain the same inflammable principle, "phlogiston," in combination with varying amounts of other substances. In 1781 Cavendish showed that water was the only substance produced when hydrogen was burned in air or oxygen, it having been thought previously to this date that other substances were formed during the reaction, A. L. Lavoisier making many experiments with the object of finding an acid among the products of combustion.

Hydrogen is found in the free state in some volcanic gases, in fumaroles, in the carnallite of the Stassfurt potash mines (H. Precht, *Ber.*, 1886, 19, p. 2326), in some meteorites, in certain stars and nebulae, and also in the envelopes of the sun. In combination it is found as a constituent of water, of the gases from certain mineral springs, in many minerals, and in most animal and vegetable tissues. It may be prepared by the electrolysis of acidulated water, by the decomposition of water by various metals or metallic hydrides, and by the action of many metals on acids or on bases. The alkali metals and alkaline earth metals decompose water at ordinary temperatures; magnesium begins to react above 70° C., and zinc at a dull red heat. The decomposition of steam by red hot iron has been studied by H. Sainte-Claire Deville (*Comptes rendus*, 1870, 70, p. 1105) and by H. Debray (*ibid.*, 1879, 88, p. 1341), who found that at about 1500° C. a condition of equilibrium is reached. H. Moissan (*Bull. soc. chim.*, 1902, 27, p. 1141) has shown that potassium hydride decomposes cold water, with evolution of hydrogen, $KH+H_2O=KOH+H_2$. Calcium hydride or hydrolite, prepared by passing hydrogen over heated calcium, decomposes water similarly, 1 gram giving 1 litre of gas; it has been proposed as a commercial source (Prats Aymerich, *Abst. J.C.S.*, 1907, ii. p. 543), as has also aluminium turnings moistened with potassium cyanide and mercuric chloride, which decomposes water regularly at 70°, 1 gram giving 1·3 litres of gas (Mauricheau-Beaupré, *Comptes rendus*, 1908, 147, p. 310). Strontium hydride behaves similarly. In preparing the gas by the action of metals on acids, dilute sulphuric or hydrochloric acid is taken, and the metals commonly used are zinc or iron. So obtained, it contains many impurities, such as carbon dioxide, nitrogen, oxides of nitrogen, phosphoretted hydrogen, arseniuretted hydrogen, &c., the removal of which is a matter of great difficulty (see E. W. Morley, *Amer. Chem. Journ.*, 1890, 12, p. 460). When prepared by the action of metals on bases, zinc or aluminium and caustic soda or caustic potash are used. Hydrogen may also be obtained by the action of zinc on ammonium salts (the nitrate excepted) (Lorin, *Comptes rendus*, 1865, 60, p. 745) and by heating the alkali formates or oxalates with caustic potash or soda, $Na_2C_2O_4+2NaOH=H_2+2Na_2CO_3$. Technically it is prepared by the action of superheated steam on incandescent coke (see F. Hembert and Henry, *Comptes rendus*, 1885, 101, p. 797; A. Naumann and C. Pistor, *Ber.*, 1885, 18, p. 1647), or by the electrolysis of a dilute solution of caustic soda (C. Winssinger, *Chem. Zeit.*, 1898, 22, p. 609; "Die Elektrizitäts-Aktiengesellschaft," *Zeit. f. Elektrochem.*, 1901, 7, p. 857). In the latter method a 15% solution of caustic soda is used, and the electrodes are made of iron; the cell is packed in a wooden box, surrounded with sand, so that the temperature is kept at about 70° C.; the solution is replenished, when necessary, with distilled water. The purity of the gas obtained is about 97%.

Pure hydrogen is a tasteless, colourless and odourless gas of specific gravity 0·06947 (air=1) (Lord Rayleigh, *Proc. Roy. Soc.*, 1893, p. 319). It may be liquefied, the liquid boiling at −252·68° C. to −252·84°C., and it has also been solidified, the solid melting at −264° C. (J. Dewar, *Comptes rendus*, 1899, 129, p. 451; *Chem. News*, 1901, 84, p. 49; see also LIQUID GASES). The specific heat of gaseous hydrogen (at constant pressure) is 3.4041 (water=1), and the ratio of the specific heat at constant pressure to the specific heat at constant volume is 1·3852 (W. C. Röntgen, *Pogg. Ann.*, 1873, 148, p. 580). On the spectrum see SPECTROSCOPY. Hydrogen is only very slightly soluble in water. It diffuses very rapidly through a porous membrane, and through some metals at a red heat (T. Graham, *Proc. Roy. Soc.*, 1867, 15, p. 223; H. Sainte-Claire Deville and L. Troost, *Comptes rendus*, 1863, 56, p. 977). Palladium and some other metals are capable of absorbing large volumes of hydrogen (especially when the metal is used as a cathode in a water electrolysis apparatus). L. Troost and P. Hautefeuille (*Ann. chim. phys.*, 1874, (5) 2, p. 279) considered that a palladium hydride of composition Pd_2H was formed, but the investigations of C. Hoitsema (*Zeit. phys. Chem.*, 1895, 17, p. 1), from the standpoint of the phase rule, do not favour this view, Hoitsema being of the opinion that the occlusion of hydrogen by palladium is a process of continuous absorption. Hydrogen burns with a pale blue non-luminous flame, but will not support the combustion of ordinary combustibles. It forms a highly explosive mixture with air or oxygen, especially when in the proportion of two volumes of hydrogen to one volume of oxygen. H. B. Baker (*Proc. Chem. Soc.*, 1902, 18, p. 40) has shown that perfectly dry hydrogen will not unite with perfectly dry oxygen. Hydrogen combines with fluorine, even at very low temperatures, with great violence; it also combines with carbon, at the temperature of the electric arc. The alkali metals when warmed in a current of hydrogen, at about 360° C., form hydrides of composition RH(R=Na, K, Rb, Cs), (H. Moissan, *Bull. soc. chim.*, 1902, 27, p. 1141); calcium and strontium similarly form hydrides CaH_2, SrH_2 at a dull red heat (A. Guntz, *Comptes rendus*, 1901, 133, p. 1209). Hydrogen is a very powerful reducing agent; the gas occluded by palladium being very active in this respect, readily reducing ferric salts to ferrous salts, nitrates to nitrites and ammonia, chlorates to chlorides, &c.

For determinations of the volume ratio with which hydrogen and oxygen combine, see J. B. Dumas, *Ann. chim. phys.*, 1843 (3), 8, p. 189; O. Erdmann and R. F. Marchand, *ibid.* p. 212; E. H. Keiser, *Ber.*, 1887, 20, p. 2323; J. P. Cooke and T. W. Richards, *Amer. Chem. Journ.*, 1888, 10, p. 191; Lord Rayleigh, *Chem. News*, 1889, 59, p. 147; E. W. Morley, *Zeit. phys. Chem.*, 1890, 20, p. 417; and S. A. Leduc, *Comptes rendus*, 1899, 128, p. 1158.

Hydrogen combines with oxygen to form two definite compounds, namely, water (*q.v.*), H_2O, and hydrogen peroxide, H_2O_2, whilst the existence of a third oxide, ozonic acid, has been indicated.

Hydrogen peroxide, H_2O_2, was discovered by L. J. Thénard in 1818 (*Ann. chim. phys.*, 8, p. 306). It occurs in small quantities in the atmosphere. It may be prepared by passing a current of carbon dioxide through ice-cold water, to which small quantities of barium peroxide are added from time to time (F. Duprey, *Comptes rendus*, 1862, 55, p. 736; A. J. Balard, *ibid.*, p. 758), $BaO_2+CO_2+H_2O=H_2O_2+BaCO_3$. E. Merck (*Abst. J.C.S.*, 1907, ii., p. 859) showed that barium percarbonate, $BaCO_4$, is formed when the gas is in excess; this substance readily yields the peroxide with an acid. Or barium peroxide may be decomposed by hydrochloric, hydrofluoric, sulphuric or silicofluoric acids (L. Crismer, *Bull. soc. chim.*, 1891 (3), 6, p. 24; Hanriot, *Comptes rendus*, 1885, 100, pp. 56, 172), the peroxide being added in small quantities to a cold dilute solution of the acid. It is necessary that it should be as pure as possible since the commercial product usually contains traces of ferric, manganic and aluminium oxides, together with some silica. To purify the oxide, it is dissolved in dilute hydrochloric acid until the acid is neatly neutralized, the solution is cooled, filtered, and baryta water is added until a faint permanent white precipitate of hydrated barium peroxide appears; the solution is now filtered, and a concentrated solution of baryta water is added to the filtrate, when a crystalline precipitate of hydrated barium peroxide, $BaO_2 8 \cdot H_2O$, is thrown down. This is filtered off and well washed with water. The above methods give a dilute aqueous solution of hydrogen peroxide, which may be concentrated somewhat by evaporation over sulphuric acid *in vacuo*. H. P. Talbot and H. R. Moody (*Jour. Anal. Chem.*, 1892, 6, p. 650) prepared a more concentrated solution from the commercial product, by the addition of a 10% solution of alcohol and baryta water. The solution is filtered, and the barium precipitated by sulphuric acid. The alcohol is removed by distillation *in vacuo*, and by further concentration *in vacuo* a solution may be obtained which evolves 580 volumes of oxygen. R. Wolffenstein (*Ber.*, 1894, 27, p. 2307) prepared practically anhydrous hydrogen peroxide (containing 99·1% H_2O_2) by first removing all traces of dust, heavy metals and alkali from the commercial 3% solution. The solution is then concentrated in an open basis on the water-bath until it contains 48% H_2O_2. The liquid so obtained is extracted with ether and the ethereal solution distilled under diminished pressure, and finally purified by repeated distillations. W. Staedel (*Zeit. f. angew. Chem.*, 1902, 15, p. 642) has described solid hydrogen peroxide, obtained by freezing concentrated solutions.

Hydrogen peroxide is also found as a product in many chemical actions, being formed when carbon monoxide and cyanogen burn in air (H. B. Dixon); by passing air through solutions of strong bases in the presence of such metals as do not react with the bases to liberate hydrogen; by shaking zinc amalgam with alcoholic sulphuric acid and air (M. Traube, *Ber.*, 1882, 15, p. 659); in the oxidation of zinc, lead and copper in presence of water, and in the electrolysis of sulphuric acid of such strength that it contains two molecules of water to one molecule of sulphuric acid (M. Berthelot, *Comptes rendus*, 1878, 86, p. 71).

The anhydrous hydrogen peroxide obtained by Wolffenstein boils at 84-85°C. (68 mm.); its specific gravity is 1·4996 (1·5° C.). It is very explosive (W. Spring, *Zeit. anorg. Chem.*, 1895, 8, p. 424). The explosion risk seems to be most marked in the preparations which have been extracted with ether previous to distillation, and J. W. Brühl (*Ber.*, 1895, 28, p. 2847) is of opinion that a very unstable, more highly oxidized product is produced in small quantity in the process. The solid variety prepared by Staedel forms colourless, prismatic crystals which melt at −2° C.; it is decomposed with explosive violence by platinum sponge, and traces of manganese dioxide. The dilute aqueous solution is very unstable, giving up oxygen readily, and decomposing with explosive violence at 100° C. An aqueous solution containing more than 1·5% hydrogen peroxide reacts slightly acid. Towards lupetidin [$\alpha\alpha'$ dimethyl piperidine, $C_5H_9N(CH_3)_2$] hydrogen peroxide acts as a dibasic acid (A. Marcuse and R. Wolffenstein, *Ber.*, 1901, 34, p. 2430; see also G. Bredig, *Zeit. Electrochem.*, 1901, 7, p. 622). Cryoscopic determinations of its molecular weight show that it is H_2O_2. [G. Carrara, *Rend. della Accad. dei Lincei*, 1892 (5), 1, ii. p. 19; W. R. Orndorff and J. White, *Amer. Chem. Journ.*, 1893, 15, p. 347.] Hydrogen peroxide behaves very frequently as a powerful oxidizing agent; thus lead sulphide is converted into lead sulphate in presence of a dilute aqueous solution of the peroxide, the hydroxides of the alkaline earth metals are converted into peroxides of the type $MO_2 \cdot 8H_2O$, titanium dioxide is converted into the trioxide, iodine is liberated from potassium iodide, and nitriles (in alkaline solution) are converted into acid-amides (B. Radziszewski, *Ber.*, 1884, 17, p. 355). In many cases it is found that hydrogen peroxide will only act as an oxidant when in the presence of a catalyst; for example, formic, glygollic, lactic, tartaric, malic, benzoic and other organic acids are readily oxidized in the presence of ferrous sulphate (H. J. H. Fenton, *Jour. Chem. Soc.*, 1900, 77, p. 69), and sugars are readily oxidized in the presence of ferric chloride (O. Fischer and M. Busch, *Ber.*, 1891, 24, p. 1871). It is sought to explain these oxidation processes by assuming that the hydrogen peroxide unites with the compound undergoing oxidation to form an addition compound, which subsequently decomposes (J. H. Kastle and A. S. Loevenhart, *Amer. Chem. Journ.*, 1903, 29, pp. 397, 517). Hydrogen peroxide can also react as a reducing agent, thus silver oxide is reduced with a rapid evolution of oxygen. The course of this reaction can scarcely be considered as definitely settled; M. Berthelot considers that a higher oxide of silver is formed, whilst A. Baeyer and V. Villiger are of opinion that reduced silver is obtained [see *Comptes rendus*, 1901, 133, p. 555; *Ann. Chim. Phys.*, 1897 (7), 11, p. 217, and *Ber.*, 1901, 34, p. 2769]. Potassium permanganate, in the presence of dilute sulphuric acid, is rapidly reduced by hydrogen peroxide, oxygen being given off, $2KM_nO_4+3H_2SO_4+5H_2O_2=K_2SO_4+2MnSO_4+8H_2O+5O_2$. Lead peroxide is reduced to the monoxide. Hypochlorous acid and its salts, together with the corresponding bromine and iodine compounds, liberate oxygen violently from hydrogen peroxide, giving hydrochloric, hydrobromic and hydriodic acids (S. Tanatar, *Ber.*, 1899, 32, p. 1013).

On the constitution of hydrogen peroxide see C. F. Schonbein, *Jour. prak. Chem.*, 1858–1868; M. Traube, *Ber.*, 1882–1889; J. W. Brühl, *Ber.*, 1895, 28, p. 2847; 1900, 33, p. 1709; S. Tanatar, *Ber.*, 1903, 36, p. 1893.

Hydrogen peroxide finds application as a bleaching agent, as an antiseptic, for the removal of the last traces of chlorine and sulphur dioxide employed in bleaching, and for various quantitative separations in analytical chemistry (P. Jannasch, *Ber.*, 1893, 26, p. 2908). It may be estimated by titration with potassium permanganate in acid solution; with potassium ferricyanide in alkaline solution, $2K_3Fe(CN)_6+2KOH+H_2O_2=2K_4Fe(CN)_6+2H_2O+O_2$; or by oxidizing arsenious acid in alkaline solution with the peroxide and back titration of the excess of arsenious acid with standard iodine (B. Grützner, *Arch. der Pharm.*, 1899, 237, p. 705). It may be recognized by the violet coloration it gives when added to a very dilute solution of potassium bichromate in the presence of hydrochloric acid; by the orange-red colour it gives with a solution of titanium dioxide in concentrated sulphuric acid; and by the precipitate of Prussian blue formed when it is added to a solution containing ferric chloride and potassium ferricyanide.

Ozonic Acid, H_2O_4. By the action of ozone on a 40% solution of potassium hydroxide, placed in a freezing mixture, an orange-brown substance is obtained, probably K_2O_4, which A. Baeyer and V. Villiger (*Ber.*, 1902, 35, p. 3038) think is derived from ozonic acid, produced according to the reaction $O_3+H_2O=H_2O_4$.

HYDROGRAPHY (Gr. ὕδωρ, water, and γράφειν, to write), the science dealing with all the waters of the earth's surface, including the description of their physical features and conditions; the preparation of charts and maps showing the position of lakes, rivers, seas and oceans, the contour of the sea-bottom, the position of shallows, deeps, reefs and the direction and volume of currents; a scientific description of the position, volume, configuration, motion and condition of all the waters of the earth. See also SURVEYING (Nautical) and OCEAN AND OCEANOGRAPHY. The Hydrographic Department of the British Admiralty, established in 1795, undertakes the making of charts for the admiralty, and is under the charge of the hydrographer to the admiralty (see CHART).

HYDROLYSIS (Gr. ὕδωρ, water, λύειν, to loosen), in chemistry, a decomposition brought about by water after the manner shown in the equation $R \cdot X+H \cdot OH=R \cdot H+X \cdot OH$. Modern research has proved that such reactions are not occasioned by water acting as H_2O, but really by its ions (hydrions and hydroxidions), for the velocity is proportional (in accordance with the law of chemical mass action) to the concentration of these ions. This fact explains the so-called "catalytic" action of acids and bases in decomposing such compounds as the esters. The term "saponification" (Lat. *sapo*, soap) has the same meaning, but it is more properly restricted to the hydrolysis of the fats, *i.e.* glyceryl esters of organic acids, into glycerin and a soap (see CHEMICAL ACTION).

HYDROMECHANICS (Gr. ὑδρομηχανικά), the science of the mechanics of water and fluids in general, including *hydrostatics* or the mathematical theory of fluids in equilibrium, and *hydromechanics*, the theory of fluids in motion. The practical application of hydromechanics forms the province of hydraulics (*q.v.*).

Historical.—The fundamental principles of hydrostatics were first given by Archimedes in his work Περὶ τῶν ὀχουμένων, or *De iis quae vehuntur in humido*, about 250 B.C., and were afterwards applied to experiments by Marino Ghetaldi (1566–1627) in his *Promotus Archimedes* (1603). Archimedes maintained that each particle of a fluid mass, when in equilibrium, is equally pressed in every direction; and he inquired into the conditions according to which a solid body floating in a fluid should assume and preserve a position of equilibrium.

In the Greek school at Alexandria, which flourished under the auspices of the Ptolemies, the first attempts were made at the construction of hydraulic machinery, and about 120 B.C. the fountain of compression, the siphon, and the forcing-pump were invented by Ctesibius and Hero. The siphon is a simple instrument; but the forcing-pump is a complicated invention, which could scarcely have been expected in the infancy of hydraulics. It was probably suggested to Ctesibius by the *Egyptian Wheel* or *Noria*, which was common at that time, and which was a kind of chain pump, consisting of a number of earthen pots carried round by a wheel. In some of these machines the pots have a valve in the bottom which enables them to descend without much resistance, and diminishes greatly the load upon the wheel; and, if we suppose that this valve was introduced so early as the time of Ctesibius, it is not difficult to perceive how such a machine might have led to the invention of the forcing-pump.

Notwithstanding these inventions of the Alexandrian school, its attention does not seem to have been directed to the motion of fluids; and the first attempt to investigate this subject was made by Sextus Julius Frontinus, inspector of the public fountains at Rome in the reigns of Nerva and Trajan. In his work *De aquaeductibus urbis Romae commentarius*, he considers the methods which were at that time employed for ascertaining the quantity of water discharged from ajutages, and the mode of distributing the waters of an aqueduct or a fountain. He remarked that the flow of water from an orifice depends not only on the magnitude of the orifice itself, but also on the height of the water in the reservoir; and that a pipe employed to carry off a portion of water from an aqueduct should, as circumstances required, have a position more or less inclined to the original direction of the current. But as he was unacquainted with the law of the velocities of running water as depending upon the depth of the orifice, the want of precision which appears in his results is not surprising.

Benedetto Castelli (1577–1644), and Evangelista Torricelli (1608–1647), two of the disciples of Galileo, applied the discoveries of their master to the science of hydrodynamics. In 1628 Castelli published a small work, *Della misura dell' acque correnti*, in which he satisfactorily explained several phenomena in the motion of fluids in rivers and canals; but he committed a great paralogism in supposing the velocity of the water proportional to the depth of the orifice below the surface of the vessel. Torricelli, observing that in a jet where the water rushed through a small ajutage it rose to nearly the same height with the reservoir from which it was supplied, imagined that it ought to move with the same velocity as if it had fallen through that height by the force of gravity, and hence he deduced the proposition that the velocities of liquids are as the square root of the head, apart from the resistance of the air and the friction of the orifice. This theorem was published in 1643, at the end of his treatise *De motu gravium projectorum*, and it was confirmed by the experiments of Raffaello Magiotti on the quantities of water discharged from different ajutages under different pressures (1648).

In the hands of Blaise Pascal (1623–1662) hydrostatics assumed the dignity of a science, and in a treatise on the equilibrium of liquids (*Sur l'équilibre des liqueurs*), found among his manuscripts after his death and published in 1663, the laws of the equilibrium of liquids were demonstrated in the most simple manner, and amply confirmed by experiments.

The theorem of Torricelli was employed by many succeeding writers, but particularly by Edmé Mariotte (1620–1684), whose *Traité du mouvement des eaux*, published after his death in the year 1686, is founded on a great variety of well-conducted experiments on the motion of fluids, performed at Versailles and Chantilly. In the discussion of some points he committed considerable mistakes. Others he treated very superficially, and in none of his experiments apparently did he attend to the diminution of efflux arising from the contraction of the liquid vein, when the orifice is merely a perforation in a thin plate; but he appears to have been the first who attempted to ascribe the discrepancy between theory and experiment to the retardation of the water's velocity through friction. His contemporary Domenico Guglielmini (1655–1710), who was inspector of the rivers and canals at Bologna, had ascribed this diminution of velocity in rivers to transverse motions arising from inequalities in their bottom. But as Mariotte observed similar obstructions even in glass pipes where no transverse currents could exist, the cause assigned by Guglielmini seemed destitute of foundation. The French philosopher, therefore, regarded these obstructions as the effects of friction. He supposed that the filaments of water which graze along the sides of the pipe lose a portion of their velocity; that the contiguous filaments, having on this account a greater velocity, rub upon the former, and suffer a diminution of their celerity; and that the other filaments are affected with similar retardations proportional to their distance from the axis of the pipe. In this way the medium velocity of the current may be diminished, and consequently the quantity of water discharged in a given time must, from the effects of friction, be considerably less than that which is computed from theory.

The effects of friction and viscosity in diminishing the velocity of running water were noticed in the *Principia* of Sir Isaac Newton, who threw much light upon several branches of hydromechanics. At a time when the Cartesian system of vortices universally prevailed, he found it necessary to investigate that hypothesis, and in the course of his investigations he showed that the velocity of any stratum of the vortex is an arithmetical mean between the velocities of the strata which enclose it; and from this it evidently follows that the velocity of a filament of water moving in a pipe is an arithmetical mean between the velocities of the filaments which surround it. Taking advantage of these results, Henri Pitot (1695–1771) afterwards showed that the retardations arising from friction are inversely as the diameters of the pipes in which the fluid moves. The attention of Newton was also directed to the discharge of water from orifices in the bottom of vessels. He supposed a cylindrical vessel full of water to be perforated in its bottom with a small hole by which the water escaped, and the vessel to be supplied with water in such a manner that it always remained full at the same height. He then supposed this cylindrical column of water to be divided into two parts,—the first, which he called the "cataract," being an hyperboloid generated by the revolution of an hyperbola of the fifth degree around the axis of the cylinder which should pass through the orifice, and the second the remainder of the water in the cylindrical vessel. He considered the horizontal strata of this hyperboloid as always in motion, while the remainder of the water was in a state of rest, and imagined that there was a kind of cataract in the middle of the fluid. When the results of this theory were compared with the quantity of water actually discharged, Newton concluded that the velocity with which the water issued from the orifice was equal to that which a falling body would receive by descending through half the height of water in the reservoir. This conclusion, however, is absolutely irreconcilable with the known fact that jets of water rise nearly to the same height as their reservoirs, and Newton seems to have been aware of this objection. Accordingly, in the second edition of his *Principia*, which appeared in 1713, he reconsidered his theory. He had discovered a contraction in the vein of fluid (*vena contracta*) which issued from the orifice, and found that, at the distance of about a diameter of the aperture, the section of the vein was contracted in the subduplicate ratio of two to one. He regarded, therefore, the section of the contracted vein as the true orifice from which the discharge of water ought to be deduced, and the velocity of the effluent water as due to the whole height of water in the reservoir; and by this means his theory became more conformable to the results of experience, though still open to serious objections. Newton was also the first to investigate the difficult subject of the motion of waves (*q.v.*).

In 1738 Daniel Bernoulli (1700–1782) published his *Hydrodynamica seu de viribus et motibus fluidorum commentarii*. His theory of the motion of fluids, the germ of which was first published in his memoir entitled *Theoria nova de motu aquarum per canales quocunque fluentes*, communicated to the Academy of St Petersburg as early as 1726, was founded on two suppositions, which appeared to him conformable to experience. He supposed that the surface of the fluid, contained in a vessel which is emptying itself by an orifice, remains always horizontal; and, if the fluid mass is conceived to be divided into an infinite number of horizontal strata of the same bulk, that these strata remain contiguous to each other, and that all their points descend vertically, with velocities inversely proportional to their breadth, or to the horizontal sections of the reservoir. In order to determine the motion of each stratum, he employed the principle of the *conservatio virium vivarum*, and obtained very elegant solutions. But in the absence of a general demonstration of that principle, his results did not command the confidence which they would otherwise have deserved, and it became desirable to have a theory more certain, and depending solely on the fundamental laws of mechanics. Colin Maclaurin (1698–1746) and John Bernoulli (1667–1748), who were of this opinion, resolved the problem by more direct methods, the one in his *Fluxions*, published in 1742, and the other in his *Hydraulica nunc primum detecta, et demonstrata directe ex fundamentis pure mechanicis*, which forms the fourth volume of his works. The method employed by Maclaurin has been thought not sufficiently rigorous; and that of John Bernoulli is, in the opinion of Lagrange, defective in clearness and precision. The theory of Daniel Bernoulli was opposed also by Jean le Rond d'Alembert. When generalizing the theory of pendulums of Jacob Bernoulli (1654–1705) he discovered a principle of dynamics so simple and general that it reduced the laws of the motions of bodies to that of their equilibrium. He applied this principle to the motion of fluids, and gave a specimen of its application at the end of his *Dynamics* in 1743. It was more fully developed in his *Traité des fluides*, published in 1744, in which he gave simple and elegant solutions of problems relating to the equilibrium and motion of fluids. He made use of the same suppositions as Daniel Bernoulli, though his calculus was established in a very different manner. He considered, at every instant, the actual motion of a stratum as composed of a motion which it had in the preceding instant and of a motion which it had lost; and the laws of equilibrium between the motions lost furnished him with equations representing the motion of the fluid. It remained a desideratum to express by equations the motion of a particle of the fluid in any assigned direction. These equations were found by d'Alembert from two principles—that a rectangular canal, taken in a mass of fluid in equilibrium, is itself in equilibrium, and that a portion of the fluid, in passing from one place to another, preserves the same volume when the fluid is incompressible, or dilates itself according to a given law when the fluid is elastic. His ingenious method, published in 1752, in his *Essai sur la résistance des fluides*, was brought to perfection in his *Opuscules mathématiques*, and was adopted by Leonhard Euler.

The resolution of the questions concerning the motion of fluids was effected by means of Euler's partial differential coefficients. This calculus was first applied to the motion of water by d'Alembert, and enabled both him and Euler to represent the theory of fluids in formulae restricted by no particular hypothesis.

One of the most successful labourers in the science of hydrodynamics at this period was Pierre Louis Georges Dubuat (1734–1809). Following in the steps of the Abbé Charles Bossut (*Nouvelles Expériences sur la résistance des fluides*, 1777), he published, in 1786, a revised edition of his *Principes d'hydraulique*, which contains a satisfactory theory of the motion of fluids, founded solely upon experiments. Dubuat considered that if water were a perfect fluid, and the channels in which it flowed infinitely smooth, its motion would be continually accelerated, like that of bodies descending in an inclined plane. But as the motion of rivers is not continually accelerated, and soon arrives at a state of uniformity, it is evident that the viscosity of the water, and the friction of the channel in which it descends, must equal the accelerating force. Dubuat, therefore, assumed it as a proposition of fundamental importance that, when water flows in any channel or bed, the accelerating force which obliges it to move is equal to the sum of all the resistances which it meets with, whether they arise from its own viscosity or from the friction of its bed. This principle was employed by him in the first edition of his work, which appeared in 1779. The theory contained in that edition was founded on the experiments of others, but he soon saw that a theory so new, and leading to results so different from the ordinary theory, should be founded on new experiments more direct than the former, and he was employed in the performance of these from 1780 to 1783. The experiments of Bossut were made only on pipes of a moderate declivity, but Dubuat used declivities of every kind, and made his experiments upon channels of various sizes.

The theory of running water was greatly advanced by the researches of Gaspard Riche de Prony (1755–1839). From a collection of the best experiments by previous workers he selected eighty-two (fifty-one on the velocity of water in conduit pipes, and thirty-one on its velocity in open canals); and, discussing these on physical and mechanical principles, he succeeded in drawing up general formulae, which afforded a simple expression for the velocity of running water.

J. A. Eytelwein (1764–1848) of Berlin, who published in 1801 a valuable compendium of hydraulics entitled *Handbuch der Mechanik und der Hydraulik*, investigated the subject of the discharge of water by compound pipes, the motions of jets and their impulses against plane and oblique surfaces; and he showed theoretically that a water-wheel will have its maximum effect when its circumference moves with half the velocity of the stream.

J. N. P. Hachette (1769–1834) in 1816–1817 published memoirs containing the results of experiments on the spouting of fluids and the discharge of vessels. His object was to measure the contracted part of a fluid vein, to examine the phenomena attendant on additional tubes, and to investigate the form of the fluid vein and the results obtained when different forms of orifices are employed. Extensive experiments on the discharge of water from orifices (*Expériences hydrauliques*, Paris, 1832) were conducted under the direction of the French government by J. V. Poncelet (1788–1867) and J. A. Lesbros (1790–1860). P. P. Boileau (1811–1891) discussed their results and added experiments of his own (*Traité de la mésure des eaux courantes*, Paris, 1854). K. R. Bornemann re-examined all these results with great care, and gave formulae expressing the variation of the coefficients of discharge in different conditions (*Civil Ingénieur*, 1880). Julius Weisbach (1806–1871) also made many experimental investigations on the discharge of fluids. The experiments of J. B. Francis (*Lowell Hydraulic Experiments*, Boston, Mass., 1855) led him to propose variations in the accepted formulae for the discharge over weirs, and a generation later a very complete investigation of this subject was carried out by H. Bazin. An elaborate inquiry on the flow of water in pipes and channels was conducted by H. G. P. Darcy (1803–1858) and continued by H. Bazin, at the expense of the French government (*Recherches hydrauliques*, Paris, 1866). German engineers have also devoted special attention to the measurement of the flow in rivers; the *Beiträge zur Hydrographie des Königreiches Böhmen* (Prague, 1872–1875) of A. R. Harlacher (1842–1890) contained valuable measurements of this kind, together with a comparison of the experimental results with the formulae of flow that had been proposed up to the date of its publication, and important data were yielded by the gaugings of the Mississippi made for the United States government by A. A. Humphreys and H. L. Abbot, by Robert Gordon's gaugings of the Irrawaddy, and by Allen J. C. Cunningham's experiments on the Ganges canal. The friction of water, investigated for slow speeds by Coulomb, was measured for higher speeds by William Froude (1810–1879), whose work is of great value in the theory of ship resistance (*Brit. Assoc. Report.*, 1869), and stream line motion was studied by Professor Osborne Reynolds and by Professor H. S. Hele Shaw. (X.)

Hydrostatics

Hydrostatics is a science which grew originally out of a number of isolated practical problems; but it satisfies the requirement of perfect accuracy in its application to phenomena, the largest and smallest, of the behaviour of a fluid. At the same time, it delights the pure theorist by the simplicity of the logic with which the fundamental theorems may be established, and by the elegance of its mathematical operations, insomuch that hydrostatics may be considered as the Euclidean pure geometry of mechanical science.

1. *The Different States of a Substance or Matter.*—All substance in nature falls into one of the two classes, solid and fluid; a solid substance, the land, for instance, as contrasted with a fluid, like water, being a substance which does not flow of itself.

A *fluid*, as the name implies, is a substance which flows, or is capable of flowing; water and air are the two fluids distributed most universally over the surface of the earth.

Fluids again are divided into two classes, termed a liquid and a gas, of which water and air are the chief examples.

A *liquid* is a fluid which is incompressible or practically so, *i.e.* it does not change in volume sensibly with change of pressure.

A *gas* is a compressible fluid, and the change in volume is considerable with moderate variation of pressure.

Liquids, again, can be poured from one open vessel into another, and can be kept in an uncovered vessel, but a gas tends to diffuse itself indefinitely and must be preserved in a closed reservoir.

The distinguishing characteristics of the three kinds of substance or states of matter, the solid, liquid and gas, are summarized thus in O. Lodge's *Mechanics*:—

A solid has both size and shape.
A liquid has size but not shape.
A gas has neither size nor shape.

2. *The Change of State of Matter.*—By a change of temperature and pressure combined, a substance can in general be made to pass from one state into another; thus by gradually increasing the temperature a solid piece of ice can be melted into the liquid state of water, and the water again can be boiled off into the gaseous state as steam. Again, by raising the temperature, a metal in the solid state can be melted and liquefied, and poured into a mould to assume any form desired, which is retained when the metal cools and solidifies again; the gaseous state of a metal is revealed by the spectroscope. Conversely, a combination of increased pressure and lowering of temperature will, if carried far enough, reduce a gas to a liquid, and afterwards to the solid state; and nearly every gaseous substance has now undergone this operation.

A certain critical temperature is observed in a gas, above which the liquefaction is impossible; so that the gaseous state has two subdivisions into (i.) a true gas, which cannot be liquefied, because its temperature is above the critical temperature, (ii.) a vapour, where the temperature is below the critical, and which can ultimately be liquefied by further lowering of temperature or increase of pressure.

3. *Plasticity and Viscosity.*—Every solid substance is found to be plastic more or less, as exemplified by punching, shearing and cutting; but the plastic solid is distinguished from the viscous fluid in that a plastic solid requires a certain magnitude of stress to be exceeded to make it flow, whereas the viscous liquid will yield to the slightest stress, but requires a certain length of time for the effect to be appreciable.

According to Maxwell (*Theory of Heat*) "When a continuous alteration of form is produced only by a stress exceeding a certain value, the substance is called a solid, however soft and plastic it may be. But when the smallest stress, if only continued long enough, will cause a perceptible and increasing change of form, the substance must be regarded as a viscous fluid, however hard it may be." Maxwell illustrates the difference between a soft solid and a hard liquid by a jelly and a block of pitch; also by the experiment of supporting a candle and a stick of sealing-wax; after a considerable time the sealing-wax will be found bent and so is a fluid, but the candle remains straight as a solid.

4. *Definition of a Fluid.*—A fluid is a substance which yields continually to the slightest tangential stress in its interior; that is, it can be divided very easily along any plane (given plenty of time if the fluid is viscous). It follows that when the fluid has come to rest, the tangential stress in any plane in its interior must vanish, and the stress must be entirely normal to the plane. This mechanical axiom of the *normality of fluid pressure* is the foundation of the mathematical theory of hydrostatics.

The theorems of hydrostatics are thus true for all stationary fluids, however, viscous they may be; it is only when we come to hydrodynamics, the science of the motion of a fluid, that viscosity will make itself felt and modify the theory; unless we begin by postulating the perfect fluid, devoid of viscosity, so that the principle of the normality of fluid pressure is taken to hold when the fluid is in movement.

5. *The Measurement of Fluid Pressure.*—The pressure at any point of a plane in the interior of a fluid is the intensity of the normal thrust estimated per unit area of the plane.

Thus, if a thrust of P ℔ is distributed uniformly over a plane area of A sq. ft., as on the horizontal bottom of the sea or any reservoir, the pressure at any point of the plane is P/A ℔ per sq. ft., or P/144A ℔ per sq. in. (lb/ft.^{2} and ℔/in.^{2}, in the Hospitalier notation, to be employed in the sequel). If the distribution of the thrust is not uniform, as, for instance, on a vertical or inclined face or wall of a reservoir, then P/A represents the average pressure over the area; and the actual pressure at any point is the average pressure over a small area enclosing the point. Thus, if a thrust ΔP ℔ acts on a small plane area ΔA ft.^{2} enclosing a point B, the pressure p at B is the limit of $\Delta P/\Delta A$; and

$$p = \mathrm{lt}(\Delta P/\Delta A) = dP/dA, \qquad (1)$$

in the notation of the differential calculus.

6. *The Equality of Fluid Pressure in all Directions.*—This fundamental principle of hydrostatics follows at once from the principle of the normality of fluid pressure implied in the definition of a fluid in § 4. Take any two arbitrary directions in the plane of the paper, and draw a small isosceles triangle *abc*, whose sides are perpendicular to the two directions, and consider the equilibrium of a small triangular prism of fluid, of which the triangle is the cross section. Let P, Q denote the normal thrust across the sides *bc*, *ca*, and R the normal thrust across the base *ab*. Then, since these three forces maintain equilibrium, and R makes equal angles with P and Q, therefore P and Q must be equal. But the faces *bc*, *ca*, over which P and Q act, are also equal, so that the pressure on each face is equal. A scalene triangle *abc* might also be employed, or a tetrahedron.

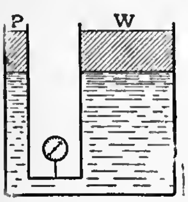

FIG. 1*a*.

It follows that the pressure of a fluid requires to be calculated in one direction only, chosen as the simplest direction for convenience.

7. *The Transmissibility of Fluid Pressure.*—Any additional pressure applied to the fluid will be transmitted equally to every point in the case of a liquid; this principle of the *transmissibility of pressure* was enunciated by Pascal, 1653, and applied by him to the invention of the *hydraulic press*.

This machine consists essentially of two communicating cylinders (fig. 1*a*), filled with liquid and closed by pistons. If a thrust P ℔ is applied to one piston of area A ft.^{2}, it will be balanced by a thrust W ℔ applied to the other piston of area B ft.^{2}, where

$$p = P/A = W/B, \qquad (1)$$

the pressure p of the liquid being supposed uniform; and, by making the ratio B/A sufficiently large, the mechanical advantage can be increased to any desired amount, and in the simplest manner possible, without the intervention of levers and machinery.

Fig. 1*b* shows also a modern form of the hydraulic press, applied to the operation of covering an electric cable with a lead coating.

8. *Theorem.*—In a fluid at rest under gravity the pressure is the same at any two points in the same horizontal plane; in other words, a surface of equal pressure is a horizontal plane.

This is proved by taking any two points A and B at the same level, and considering the equilibrium of a thin prism of liquid AB, bounded by planes at A and B perpendicular to AB. As gravity and the fluid pressure on the sides of the prism act at right angles to AB, the equilibrium requires the equality of thrust on the ends A and B; and as the areas are equal, the pressure must be equal at A and B; and so the pressure is the same at all points in the same horizontal plane. If the fluid is a liquid, it can have a free surface without diffusing itself, as a gas would; and this free surface, being a surface of zero pressure, or more generally of uniform atmospheric pressure, will also be a surface of equal pressure, and therefore a horizontal plane.

Hence the *theorem*.—The free surface of a liquid at rest under gravity is a horizontal plane. This is the characteristic distinguishing between a solid and a liquid; as, for instance, between land and water. The land has hills and valleys, but the surface of water at rest is a horizontal plane; and if disturbed the surface moves in waves.

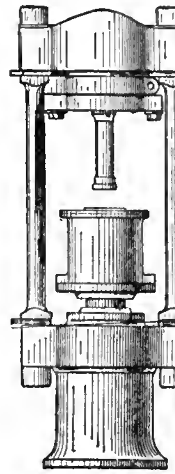

FIG. 1*b*.

9. *Theorem.*—In a homogeneous liquid at rest under gravity the pressure increases uniformly with the depth.

This is proved by taking the two points A and B in the same vertical line, and considering the equilibrium of the prism by resolving vertically. In this case the thrust at the lower end B must exceed the thrust at A, the upper end, by the weight of the prism of liquid; so that, denoting the cross section of the prism by α ft.^{2}, the pressure at A and By by p_0 and p lb/ft.^{2}, and by w the density of the liquid estimated in ℔/ft.^{3},

$$p\alpha - p_0\alpha = w\alpha.\,AB, \qquad (1)$$

$$p = \omega.AB + p_0. \qquad (2)$$

Thus in water, where $w = 62{\cdot}4$lb/ft.^{3}, the pressure increases 62·4 ℔/ft.^{2}, or $62{\cdot}4 \div 144 = 0{\cdot}433$ ℔/in.^{2} for every additional foot of depth.

10. *Theorem.*—If two liquids of different density are resting in vessels in communication, the height of the free surface of such liquid above the surface of separation is inversely as the density.

For if the liquid of density σ rises to the height h and of density ρ to the height k, and p_0 denotes the atmospheric pressure, the pressure in the liquid at the level of the surface of separation will be $\sigma h + p_0$ and $\rho k + p_0$, and these being equal we have

$$\sigma h = \rho k. \qquad (1)$$

The principle is illustrated in the article BAROMETER, where a column of mercury of density σ and height h, rising in the tube to the Torricellian vacuum, is balanced by a column of air of density ρ, which may be supposed to rise as a homogeneous fluid to a height k, called the height of the homogeneous atmosphere. Thus water being about 800 times denser than air and mercury 13·6 times denser than water,

$$k/h = \sigma/\rho = 800 \times 13{\cdot}6 = 10{,}880; \qquad (2)$$

and with an average barometer height of 30 in. this makes k 27,200 ft., about 8300 metres.

11. *The Head of Water or a Liquid.*—The pressure σh at a depth h ft. in liquid of density σ is called the pressure due to a *head* of h ft. of the liquid. The atmospheric pressure is thus due to an average head of 30 in. of mercury, or $30 \times 13{\cdot}6 \div 12 = 34$ ft. of water, or 27,200 ft. of air. The pressure of the air is a convenient unit to employ in practical work, where it is called an "atmosphere"; it is made the equivalent of a pressure of one kg/cm^2; and one ton/inch^2, employed as the unit with high pressure as in artillery, may be taken as 150 atmospheres.

12. *Theorem.*—A body immersed in a fluid is buoyed up by a force equal to the weight of the liquid displaced, acting vertically upward through the centre of gravity of the displaced liquid.

For if the body is removed, and replaced by the fluid as at first, this fluid is in equilibrium under its own weight and the thrust of the surrounding fluid, which must be equal and opposite, and the surrounding fluid acts in the same manner when the body replaces the displaced fluid again; so that the resultant thrust of the fluid acts vertically upward through the centre of gravity of the fluid displaced, and is equal to the weight.

When the body is floating freely like a ship, the equilibrium of this liquid thrust with the weight of the ship requires that the weight of water displaced is equal to the weight of the ship and the two centres of gravity are in the same vertical line. So also a balloon begins to rise when the weight of air displaced is greater than the weight of the balloon, and it is in equilibrium when the weights are equal. This theorem is called generally the *principle of Archimedes*.

It is used to determine the density of a body experimentally; for if W is the weight of a body weighed in a balance in air (strictly *in vacuo*), and if W′ is the weight required to balance when the body is suspended in water, then the upward thrust of the liquid or weight of liquid displaced is W–W′, so that the *specific gravity* (S.G.), defined as the ratio of the weight of a body to the weight of an equal volume of water, is W/(W–W′).

As stated first by Archimedes, the principle asserts the obvious fact that a body displaces its own volume of water; and he utilized it in the problem of the determination of the adulteration of the crown of Hiero. He weighed out a lump of gold and of silver of the same weight as the crown; and, immersing the three in succession in water, he found they spilt over measures of water in the ratio $\frac{1}{14}:\frac{4}{77}:\frac{2}{21}$ or 33: 24: 44; thence it follows that the gold: silver alloy of the crown was as 11 : 9 by weight.

13. *Theorem.*—The resultant vertical thrust on any portion of a curved surface exposed to the pressure of a fluid at rest under gravity is the weight of fluid cut out by vertical lines drawn round the boundary of the curved surface.

Theorem.—The resultant horizontal thrust in any direction is obtained by drawing parallel horizontal lines round the boundary, and intersecting a plane perpendicular to their direction in a plane curve; and then investigating the thrust on this plane area, which will be the same as on the curved surface.

The proof of these theorems proceeds as before, employing the normality principle; they are required, for instance, in the determination of the liquid thrust on any portion of the bottom of a ship.

In casting a thin hollow object like a bell, it will be seen that the resultant upward thrust on the mould may be many times greater than the weight of metal; many a curious experiment has been devised to illustrate this property and classed as a hydrostatic paradox (Boyle, *Hydrostatical Paradoxes*, 1666).

Consider, for instance, the operation of casting a hemispherical bell, in fig. 2. As the molten metal is run in, the upward thrust on the outside mould, when the level has reached PP′, is the weight of metal in the volume generated by the revolution of APQ; and this, by a theorem of Archimedes, has the same volume as the cone ORR′, or $\frac{1}{3}\pi y^3$, where y is the depth of metal, the horizontal sections being equal so long as y is less than the radius of the outside hemisphere. Afterwards, when the metal has risen above B, to the level KK′, the additional thrust is the weight of the cylinder of diameter KK′ and height BH. The upward thrust is the same, however thin the metal may be in the interspace between the outer mould and the core inside; and this was formerly considered paradoxical.

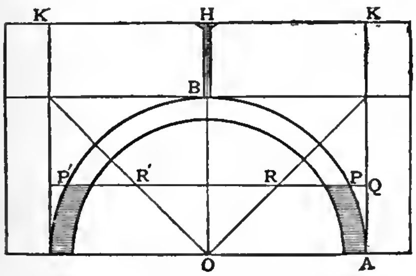

Fig. 2.

Analytical Equations of Equilibrium of a Fluid at rest under any System of Force.

14. Referred to three fixed coordinate axes, a fluid, in which the pressure is p, the density ρ, and X, Y, Z the components of impressed force per unit mass, requires for the equilibrium of the part filling a fixed surface S, on resolving parallel to Ox,

$$\iint lp\,dS = \iiint \rho X\,dx\,dy\,dz, \tag{1}$$

where l, m, n denote the direction cosines of the normal drawn outward of the surface S.

But by Green's transformation

$$\iint lp\,dS = \iiint \frac{dp}{dx}\,dx\,dy\,dz, \tag{2}$$

thus leading to the differential relation at every point

$$\frac{dp}{dx}=\rho X,\quad \frac{dp}{dy}=\rho Y,\quad \frac{dp}{dz}=\rho Z. \tag{3}$$

The three equations of equilibrium obtained by taking moments round the axes are then found to be satisfied identically.

Hence the space variation of the pressure in any direction, or the *pressure-gradient*, is the resolved force per unit volume in that direction. The resultant force is therefore in the direction of the steepest pressure-gradient, and this is normal to the surface of equal pressure; for equilibrium to exist in a fluid the lines of force must therefore be capable of being cut orthogonally by a system of surfaces, which will be surfaces of equal pressure.

Ignoring temperature effect, and taking the density as a function of the pressure, surfaces of equal pressure are also of equal density, and the fluid is stratified by surfaces orthogonal to the lines of force;

$$\frac{1}{\rho}\frac{dp}{dx},\ \frac{1}{\rho}\frac{dp}{dy},\ \frac{1}{\rho}\frac{dp}{dz},\ \text{or X, Y, Z} \tag{4}$$

are the partial differential coefficients of some function P, $=\int dp/\rho$, of x, y, z; so that X, Y, Z must be the partial differential coefficients of a potential –V, such that the force in any direction is the downward gradient of V; and then

$$\frac{dP}{dx}+\frac{dV}{dx}=0,\ \text{or P+V = constant}, \tag{5}$$

in which P may be called the hydrostatic head and V the head of potential.

With variation of temperature, the surfaces of equal pressure and density need not coincide; but, taking the pressure, density and temperature as connected by some relation, such as the gas-equation, the surfaces of equal density and temperature must intersect in lines lying on a surface of equal pressure.

15. As an example of the general equations, take the simplest case of a uniform field of gravity, with Oz directed vertically downward; employing the gravitation unit of force,

$$\frac{1}{\rho}\frac{dp}{dx}=0,\ \frac{1}{\rho}\frac{dp}{dy}=0,\ \frac{1}{\rho}\frac{dp}{dz}=1, \tag{1}$$

$$P=\int dp/\rho = z + \text{a constant}. \tag{2}$$

When the density ρ is uniform, this becomes, as before in (2) § 9

$$p=\rho z+p_0. \tag{3}$$

Suppose the density ρ varies as some nth power of the depth below O, then

$$dp/dz=\rho=\mu z^n \tag{4}$$

$$p=\mu\frac{z^{n+1}}{n+1}=\frac{\rho z}{n+1}=\frac{\rho}{n+1}\left(\frac{\rho}{\mu}\right)^{1/n}, \tag{5}$$

supposing p and ρ to vanish together.

These equations can be made to represent the state of convective equilibrium of the atmosphere, depending on the gas-equation

$$p=\rho k=R\rho\theta, \tag{6}$$

where θ denotes the absolute temperature; and then

$$R\frac{d\theta}{dz}=\frac{d}{dz}\left(\frac{p}{\rho}\right)=\frac{1}{n+1}, \tag{7}$$

so that the temperature-gradient $d\theta/dz$ is constant, as in convective equilibrium in (11).

From the gas-equation in general, in the atmosphere

$$\frac{1}{\rho}\frac{d\rho}{dz}=\frac{1}{p}\frac{dp}{dz}-\frac{1}{\theta}\frac{d\theta}{dz}=\frac{\rho}{p}-\frac{1}{\theta}\frac{d\theta}{dz}=\frac{1}{k}-\frac{1}{\theta}\frac{d\theta}{dz}, \tag{8}$$

which is positive, and the density ρ diminishes with the ascent, provided the temperature-gradient $d\theta/dz$ does not exceed θ/k.

With uniform temperature, taking k constant in the gas-equation,

$$dp/dz=\rho=p/k,\quad p=p_0e^{z/k}, \tag{9}$$

so that in ascending in the atmosphere of thermal equilibrium the pressure and density diminish at compound discount, and for pressures p_1 and p_2 at heights z_1 and z_2

$$(z_1-z_2)/k=\log_e(p_2/p_1)=2{\cdot}3\log_{10}(p_2/p_1). \tag{10}$$

In the convective equilibrium of the atmosphere, the air is supposed to change in density and pressure without exchange of heat by conduction; and then

$$\rho/\rho_0=(\theta/\theta_0)^n,\ p/p_0=(\theta/\theta_0)^{n+1}, \tag{11}$$

$$\frac{dz}{d\theta}=\frac{1}{\rho}\frac{dp}{d\theta}=(n+1)\frac{p}{\rho\theta}=(n+1)R,\ \ \gamma=1+\frac{1}{n},$$

where γ is the ratio of the specific heat at constant pressure and constant volume.

In the more general case of the convective equilibrium of a spherical atmosphere surrounding the earth, of radius a,

$$\frac{dp}{\rho}=(n+1)\frac{p_0}{\rho_0}\frac{d\theta}{\theta_0}=-\frac{a^2}{r^2}dr, \tag{12}$$

gravity varying inversely as the square of the distance r from the centre; so that, $k=p_0/\rho_0$, denoting the height of the homogeneous atmosphere at the surface, θ is given by

$$(n+1)k(1-\theta/\theta_0)=a(1-a/r), \tag{13}$$

or if c denotes the distance where $\theta=0$,

$$\frac{\theta}{\theta_0}=\frac{a}{r}\cdot\frac{c-r}{c-a}. \tag{14}$$

When the compressibility of water is taken into account in a deep ocean, an experimental law must be employed, such as

$$p-p_0=k(\rho-\rho_0),\ \text{or}\ \rho/\rho_0=1+(p-p_0)/\lambda,\ \lambda=k\rho_0, \tag{15}$$

so that λ is the pressure due to a head k of the liquid at density ρ_0 under atmospheric pressure p_0; and it is the gauge pressure required on this law to double the density. Then

$$dp/dz=k\,d\rho/dz=\rho,\quad \rho=\rho_0e^{z/k},\quad p-p_0=k\rho_0(e^{z/k}-1); \tag{16}$$

and if the liquid was incompressible, the depth at pressure p would be $(p-p_0)/p_0$, so that the lowering of the surface due to compression is

$$ke^{z/k}-k-z=\tfrac{1}{2}z^2/k,\ \text{when } k \text{ is large}. \tag{17}$$

For sea water, λ is about 25,000 atmospheres, and k is then 25,000 times the height of the water barometer, about 250,000 metres, so that in an ocean 10 kilometres deep the level is lowered about 200 metres by the compressibility of the water; and the density at the bottom is increased 4 %.

On another physical assumption of constant cubical elasticity λ,

$$dp=\lambda\,d\rho/\rho,\quad (p-p_0)/\lambda=\log(\rho/\rho_0), \tag{18}$$

$$\frac{dp}{zd}=\frac{\lambda}{\rho}\frac{d\rho}{dz}=\rho,\quad \lambda\left(\frac{1}{\rho_0}-\frac{1}{\rho}\right)=z,\quad 1-\frac{\rho_0}{\rho}=\frac{z}{k},\quad \lambda=k\rho_0, \tag{19}$$

and the lowering of the surface is

$$\frac{p-p_0}{\rho_0}-z=k\log\frac{\rho}{\rho_0}-z=-k\log\left(1-\frac{z}{k}\right)-z\approx\frac{z^2}{2k}\qquad(20)$$

as before in 17).

16. *Centre of Pressure.*—A plane area exposed to fluid pressure on one side experiences a single resultant thrust, the integrated pressure over the area, acting through a definite point called the centre of pressure (C.P.) of the area.

Thus if the plane is normal to Oz, the resultant thrust

$$R=\iint p\,dx\,dy,\qquad(1)$$

and the co-ordinates $\bar{x}$, $\bar{y}$ of the C.P. are given by

$$\bar{x}R=\iint xp\,dx\,dy,\quad \bar{y}R=\iint yp\,dx\,dy.\qquad(2)$$

The C.P. is thus the C.G. of a plane lamina bounded by the area, in which the surface density is p.

If p is uniform, the C.P. and C.G. of the area coincide.

For a homogeneous liquid at rest under gravity, p is proportional to the depth below the surface, *i.e.* to the perpendicular distance from the line of intersection of the plane of the area with the free surface of the liquid.

If the equation of this line, referred to new coordinate axes in the plane area, is written

$$x\cos\alpha+y\sin\alpha-h=0,\qquad(3)$$

$$R=\iint\rho(h-x\cos\alpha-y\sin\alpha)dx\,dy,\qquad(4)$$

$$\bar{x}R=\iint\rho x(h-x\cos\alpha-y\sin\alpha)dx\,dy,\qquad(5)$$

$$\bar{y}R=\iint\rho y(h-x\cos\alpha-y\sin\alpha)dx\,dy.$$

Placing the new origin at the C.G. of the area A,

$$\iint x\,dx\,dy=0,\quad\iint y\,dx\,dy=0,\qquad(6)$$

$$R=\rho hA,\qquad(7)$$

$$\bar{x}hA=-\cos\alpha\iint x^2dA-\sin\alpha\iint xy\,dA,\qquad(8)$$

$$\bar{y}hA=-\cos\alpha\iint xy\,dA-\sin\alpha\iint y^2dA.\qquad(9)$$

Turning the axes to make them coincide with the principal axes of the area A, thus making $\iint xy\,dA=0$,

$$\bar{x}h=-a^2\cos\alpha,\ \bar{y}h=-b^2\sin\alpha,\qquad(10)$$

where

$$\iint x^2dA=Aa^2,\quad\iint y^2dA=Ab^2,\qquad(11)$$

a and b denoting the semi-axes of the momental ellipse of the area.

This shows that the C.P. is the antipole of the line of intersection of its plane with the free surface with respect to the momental ellipse at the C.G. of the area.

Thus the C.P. of a rectangle or parallelogram with a side in the surface is at $\frac{2}{3}$ of the depth of the lower side; of a triangle with a vertex in the surface and base horizontal is $\frac{3}{4}$ of the depth of the base; but if the base is in the surface, the C.P. is at half the depth of the vertex; as on the faces of a tetrahedron, with one edge in the surface.

The *core* of an area is the name given to the limited area round its C.G. within which the C.P. must lie when the area is immersed completely; the boundary of the core is therefore the locus of the antipodes with respect to the momental ellipse of water lines which touch the boundary of the area. Thus the core of a circle or an ellipse is a concentric circle or ellipse of one quarter the size.

The C.P. of water lines passing through a fixed point lies on a straight line, the antipolar of the point; and thus the core of a triangle is a similar triangle of one quarter the size, and the core of a parallelogram is another parallelogram, the diagonals of which are the middle third of the median lines.

In the design of a structure such as a tall reservoir dam it is important that the line of thrust in the material should pass inside the core of a section, so that the material should not be in a state of tension anywhere and so liable to open and admit the water.

17. *Equilibrium and Stability of a Ship or Floating Body. The Metacentre.*—The principle of Archimedes in § 12 leads immediately to the conditions of equilibrium of a body supported freely in fluid, like a fish in water or a balloon in the air, or like a ship (fig. 3) floating partly immersed in water and the rest in air. The body is in equilibrium under two forces:—(i.) its weight W acting vertically downward through G, the C.G. of the body, and (ii.) the buoyancy of the fluid, equal to the weight of the displaced fluid, and acting vertically upward through B, the C.G. of the displaced fluid; for equilibrium these two forces must be equal and opposite in the same line.

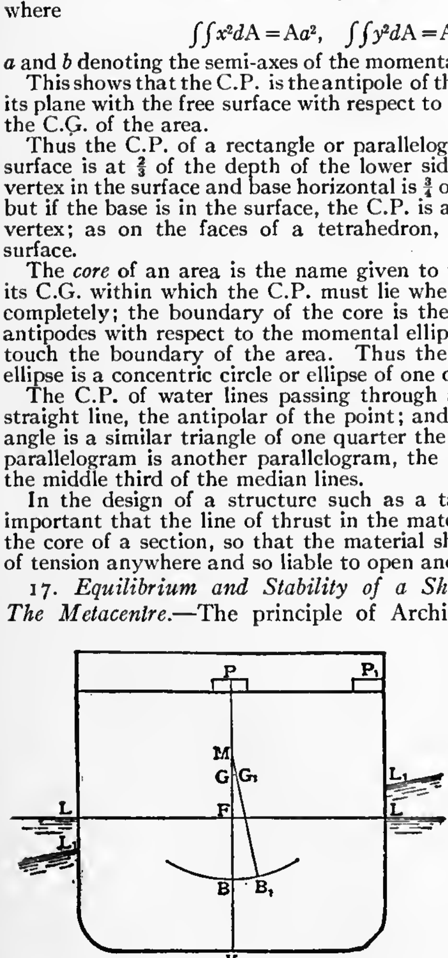

FIG. 3.

The conditions of equilibrium of a body, floating like a ship on the surface of a liquid, are therefore:—

(i.) the weight of the body must be less than the weight of the total volume of liquid it can displace; or else the body will sink to the bottom of the liquid; the difference of the weights is called the "reserve of buoyancy."

(ii.) the weight of liquid which the body displaces in the position of equilibrium is equal to the weight W of the body; and

(iii.) the C.G., B, of the liquid displaced and G of the body, must lie in the same vertical line GB.

18. In addition to satisfying these conditions of equilibrium, a ship must fulfil the further condition of stability, so as to keep upright; if displaced slightly from this position, the forces called into play must be such as to restore the ship to the upright again. The stability of a ship is investigated practically by inclining it; a weight is moved across the deck and the angle is observed of the heel produced.

Suppose P tons is moved c ft. across the deck of a ship of W tons displacement; the C.G. will move from G to G_1 the reduced distance $G_1G_2=c$ (P/W); and if B, called the centre of buoyancy, moves to B_1, along the curve of buoyancy BB_1, the normal of this curve at B_1 will be the new vertical B_1G_1, meeting the old vertical in a point M, the centre of curvature of BB_1, called the *metacentre*.

If the ship heels through an angle θ or a slope of 1 in m,

$$GM=GG_1\cot\theta=mc(P/W),\qquad(1)$$

and GM is called the metacentric height; and the ship must be ballasted, so that G lies below M. If G was above M, the tangent drawn from G to the evolute of B, and normal to the curve of buoyancy, would give the vertical in a new position of equilibrium. Thus in H.M.S. "Achilles" of 9000 tons displacement it was found that moving 20 tons across the deck, a distance of 42 ft., caused the bob of a pendulum 20 ft. long to move through 10 in., so that

$$GM=\frac{240}{10}\times42\times\frac{20}{9000}=2{\cdot}24\text{ ft.};\qquad(2)$$

also

$$\cot\theta=24,\quad\theta=2°\,24'.\qquad(3)$$

In a diagram it is conducive to clearness to draw the ship in one position, and to incline the water-line; and the page can be turned if it is desired to bring the new water-line horizontal.

Suppose the ship turns about an axis through F in the water-line area, perpendicular to the plane of the paper; denoting by y the distance of an element dA if the water-line area from the axis of rotation, the change of displacement is $\Sigma y\,dA\tan\theta$, so that there is no change of displacement if $\Sigma y\,dA=0$, that is, if the axis passes through the C.G. of the water-line area, which we denote by F and call the centre of flotation.

The righting couple of the wedges of immersion and emersion will be

$$\Sigma wy\,dA\tan\theta.y=w\tan\theta\Sigma y^2dA=w\tan\theta.Ak^2\text{ ft. tons},\qquad(4)$$

w denoting the density of water in tons/ft.³, and $W=wV$, for a displacement of V ft.³

This couple, combined with the original buoyancy W through B, is equivalent to the new buoyancy through B, so that

$$W.BB_1=wAk^2\tan\theta,\qquad(5)$$

$$BM=BB_1\cot\theta=Ak^2/V,\qquad(6)$$

giving the radius of curvature BM of the curve of buoyancy B, in terms of the displacement V, and Ak^2 the moment of inertia of the water-line area about an axis through F, perpendicular to the plane of displacement.

An inclining couple due to moving a weight about in a ship will heel the ship about an axis perpendicular to the plane of the couple, only when this axis is a principal axis at F of the momental ellipse of the water-line area A. For if the ship turns through a small angle θ about the line FF′, then b_1, b_2, the C.G. of the wedge of immersion and emersion, will be the C.P. with respect to FF′ of the two parts of the water-line area, so that b_1b_2 will be conjugate to FF′ with respect to the momental ellipse at F.

The naval architect distinguishes between the *stability of form*, represented by the righting couple W.BM, and the *stability of ballasting*, represented by W.BG. Ballasted with G at B, the righting couple when the ship is heeled through θ is given by W.BM. tan θ; but if weights inside the ship are raised to bring G above B, the righting couple is diminished by W.BG. tan θ, so that the resultant righting couple is W.GM. tan θ. Provided the ship is designed to float upright at the smallest draft with no load on board, the stability at any other draft of water can be arranged by the stowage of the weight, high or low.

19. Proceeding as in § 16 for the determination of the C.P. of an area, the same argument will show that an inclining couple due to

the movement of a weight P through a distance c will cause the ship to heel through an angle θ about an axis FF′ through F, which is conjugate to the direction of the movement of P with respect to an ellipse, not the momental ellipse of the water-line area A, but a confocal to it, of squared semi-axes

$$a^2-h\mathrm{V/A},\ b^2-h\mathrm{V/A}, \qquad (1)$$

h denoting the vertical height BG between C.G. and centre of buoyancy. The varying direction of the inclining couple Pc may be realized by swinging the weight P from a crane on the ship, in a circle of radius c. But if the weight P was lowered on the ship from a crane on shore, the vessel would sink bodily a distance P/wA if P was deposited over F; but deposited anywhere else, say over Q on the water-line area, the ship would turn about a line the antipolar of Q with respect to the confocal ellipse, parallel to FF′, at a distance FK from F

$$\mathrm{FK}=(k^2-h\mathrm{V/A})/\mathrm{FQ}\sin \mathrm{QFF'} \qquad (2)$$

through an angle θ or a slope of one in m, given by

$$\sin\theta=\frac{1}{m}=\frac{\mathrm{P}}{w\mathrm{A}\,.\,\mathrm{FK}}=\frac{\mathrm{P}}{\mathrm{W}}\cdot\frac{\mathrm{V}}{\mathrm{A}k^2-h\mathrm{V}}\mathrm{FQ}\sin\mathrm{QFF'}, \qquad (3)$$

where k denotes the radius of gyration about FF′ of the water-line area. Burning the coal on a voyage has the reverse effect on a steamer.

Hydrodynamics

20. In considering the motion of a fluid we shall suppose it non-viscous, so that whatever the state of motion the stress across any section is normal, and the principle of the normality and thence of the equality of fluid pressure can be employed, as in hydrostatics. The practical problems of fluid motion, which are amenable to mathematical analysis when viscosity is taken into account, are excluded from treatment here, as constituting a separate branch called "hydraulics" (*q.v.*). Two methods are employed in hydrodynamics, called the Eulerian and Lagrangian, although both are due originally to Leonhard Euler. In the Eulerian method the attention is fixed on a particular point of space, and the change is observed there of pressure, density and velocity, which takes place during the motion; but in the Lagrangian method we follow up a particle of fluid and observe how it changes. The first may be called the statistical method, and the second the historical, according to J. C. Maxwell. The Lagrangian method being employed rarely, we shall confine ourselves to the Eulerian treatment.

The Eulerian Form of the Equations of Motion.

21. The first equation to be established is the *equation of continuity*, which expresses the fact that the increase of matter within a fixed surface is due to the flow of fluid across the surface into its interior.

In a straight uniform current of fluid of density ρ, flowing with velocity q, the flow in units of mass per second across a plane area A, placed in the current with the normal of the plane making an angle θ with the velocity, is $\rho\mathrm{A}q\cos\theta$, the product of the density ρ, the area A, and $q\cos\theta$ the component velocity normal to the plane.

Generally if S denotes any closed surface, fixed in the fluid, M the mass of the fluid inside it at any time t, and θ the angle which the outward-drawn normal makes with the velocity q at that point,

$$d\mathrm{M}/dt = \text{rate of increase of fluid inside the surface,} \qquad (1)$$
$$= \text{flux across the surface into the interior}$$
$$= -\iint \rho q\cos\theta\, d\mathrm{S},$$

the integral equation of continuity.

In the Eulerian notation u, v, w denote the components of the velocity q parallel to the coordinate axes at any point (x, y, z) at the time t; u, v, w are functions of x, y, z, t, the independent variables; and d is used here to denote partial differentiation with respect to any one of these four independent variables, all capable of varying one at a time.

To transfer the integral equation into the differential equation of continuity, Green's transformation is required again, namely,

$$\iiint\left(\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}\right)dxdydz=\iint(l\xi+m\eta+n\zeta)d\mathrm{S}, \qquad (2)$$

or individually

$$\iiint\frac{d\xi}{dx}dxdydz=\iint l\xi d\mathrm{S},\ldots, \qquad (3)$$

where the integrations extend throughout the volume and over the surface of a closed space S; l, m, n denoting the direction cosines of the outward-drawn normal at the surface element dS, and ξ, η, ζ any continuous functions of x, y, z.

The integral equation of continuity (1) may now be written

$$\iiint\frac{d\rho}{dt}dxdydz+\iint(l\rho u+m\rho v+n\rho w)d\mathrm{S}=0, \qquad (4)$$

which becomes by Green's transformation

$$\iiint\left(\frac{d\rho}{dt}+\frac{d(\rho u)}{dx}+\frac{d(\rho v)}{dy}+\frac{d(\rho w)}{dz}\right)dxdydz=0, \qquad (5)$$

leading to the differential equation of continuity when the integration is removed.

22. The equations of motion can be established in a similar way by considering the rate of increase of momentum in a fixed direction of the fluid inside the surface, and equating it to the momentum generated by the force acting throughout the space S, and by the pressure acting over the surface S.

Taking the fixed direction parallel to the axis of x, the time-rate of increase of momentum, due to the fluid which crosses the surface, is

$$-\iint\rho uq\cos\theta d\mathrm{S}=-\iint(l\rho u^2+m\rho uv+n\rho uw)d\mathrm{S}, \qquad (1)$$

which by Green's transformation is

$$-\iiint\left(\frac{d(\rho u^2)}{dx}+\frac{d(\rho uv)}{dy}+\frac{d(\rho uw)}{dz}\right)dxdydz. \qquad (2)$$

The rate of generation of momentum in the interior of S by the component of force, X per unit mass, is

$$\iiint\rho\mathrm{X}dxdydz, \qquad (3)$$

and by the pressure at the surface S is

$$-\iint lpd\mathrm{S}=-\iiint\frac{dp}{dx}dxdydz, \qquad (4)$$

by Green's transformation.

The time rate of increase of momentum of the fluid inside S is

$$\iiint\frac{d(\rho u)}{dt}dxdydz; \qquad (5)$$

and (5) is the sum of (1), (2), (3), (4), so that

$$\iiint\left(\frac{d\rho u}{dt}+\frac{d\rho u^2}{dx}+\frac{d\rho uv}{dy}+\frac{d\rho uw}{dz}-\rho\mathrm{X}+\frac{dp}{dx}\right)dxdydz=0, \qquad (6)$$

leading to the differential equation of motion

$$\frac{d\rho u}{dt}+\frac{d\rho u^2}{dx}+\frac{d\rho uv}{dy}+\frac{d\rho uw}{dz}=\rho\mathrm{X}-\frac{dp}{dx}, \qquad (7)$$

with two similar equations.

The absolute unit of force is employed here, and not the gravitation unit of hydrostatics; in a numerical application it is assumed that C.G.S. units are intended.

These equations may be simplified slightly, using the equation of continuity (5) § 21; for

$$\begin{aligned}&\frac{d\rho u}{dt}+\frac{d\rho u^2}{dx}+\frac{d\rho uv}{dy}+\frac{d\rho uw}{dz}\\&=\rho\left(\frac{du}{dt}+u\frac{du}{dx}+v\frac{du}{dy}+w\frac{du}{dz}\right)\\&\quad+u\left(\frac{d\rho}{dt}+\frac{d\rho u}{dx}+\frac{d\rho v}{dy}+\frac{d\rho w}{dz}\right),\end{aligned} \qquad (8)$$

reducing to the first line, the second line vanishing in consequence of the equation of continuity; and so the equation of motion may be written in the more usual form

$$\frac{du}{dt}+u\frac{du}{dx}+v\frac{du}{dy}+w\frac{du}{dz}=\mathrm{X}-\frac{1}{\rho}\frac{dp}{dx}, \qquad (9)$$

with the two others

$$\frac{dv}{dt}+u\frac{dv}{dx}+v\frac{dv}{dy}+w\frac{dv}{dz}=\mathrm{Y}-\frac{1}{\rho}\frac{dp}{dy}, \qquad (10)$$

$$\frac{dw}{dt}+u\frac{dw}{dx}+v\frac{dw}{dy}+w\frac{dw}{dz}=\mathrm{Z}-\frac{1}{\rho}\frac{dp}{dz}. \qquad (11)$$

23. As a rule these equations are established immediately by determining the component acceleration of the fluid particle which is passing through (x, y, z) at the instant t of time considered, and saying that the reversed acceleration or kinetic reaction, combined with the impressed force per unit of mass and pressure-gradient, will according to d'Alembert's principle form a system in equilibrium.

To determine the component acceleration of a particle, suppose F to denote any function of x, y, z, t, and investigate the time rate of F for a moving particle; denoting the change by DF/dt,

$$\begin{aligned}\frac{\mathrm{DF}}{dt}&=\mathrm{lt.}\frac{\mathrm{F}(x+u\delta t,\ y+v\delta t,\ z+w\delta t,\ t+\delta t)-\mathrm{F}(x,\ y,\ z,\ t)}{\delta t}\\&=\frac{d\mathrm{F}}{dt}+u\frac{d\mathrm{F}}{dx}+v\frac{d\mathrm{F}}{dy}+w\frac{d\mathrm{F}}{dz};\end{aligned} \qquad (1)$$

and D/dt is called particle differentiation, because it follows the rate of change of a particle as it leaves the point x, y, z; but

$$d\mathrm{F}/dt,\ d\mathrm{F}/dx,\ d\mathrm{F}/dy,\ d\mathrm{F}/dz \qquad (2)$$

represent the rate of change of F at the time t, at the point, x, y, z, fixed in space.

The components of acceleration of a particle of fluid are consequently

$$\frac{Du}{dt}=\frac{du}{dt}+u\frac{du}{dx}+v\frac{du}{dy}+w\frac{du}{dz}, \qquad (3)$$

$$\frac{Dv}{dt}=\frac{dv}{dt}+u\frac{dv}{dx}+v\frac{dv}{dy}+w\frac{dv}{dz}, \qquad (4)$$

$$\frac{Dw}{dt}=\frac{dw}{dt}+u\frac{dw}{dx}+v\frac{dw}{dy}+w\frac{dw}{dz}, \qquad (5)$$

leading to the equations of motion above.

If F $(x, y, z, t)=0$ represents the equation of a surface containing always the same particles of fluid,

$$\frac{DF}{dt}=0, \text{ or } \frac{dF}{dt}+u\frac{dF}{dx}+v\frac{dF}{dy}+w\frac{dF}{dz}=0, \qquad (6)$$

which is called the differential equation of the *bounding surface*. A bounding surface is such that there is no flow of fluid across it, as expressed by equation (6). The surface always contains the same fluid inside it, and condition (6) is satisfied over the complete surface, as well as any part of it.

But turbulence in the motion will vitiate the principle that a bounding surface will always consist of the same fluid particles, as we see on the surface of turbulent water.

24. To integrate the equations of motion, suppose the impressed force is due to a potential V, such that the force in any direction is the rate of diminution of V, or its downward gradient; and then

$$X=-dV/dx,\ Y=-dV/dy,\ Z=-dV/dz; \qquad (1)$$

and putting

$$\frac{dw}{dy}-\frac{dv}{dz}=2\xi,\ \frac{du}{dz}-\frac{dw}{dx}=2\eta,\ \frac{dv}{dx}-\frac{du}{dy}=2\zeta, \qquad (2)$$

$$\frac{d\xi}{dx}+\frac{d\eta}{dy}+\frac{d\zeta}{dz}=0, \qquad (3)$$

the equations of motion may be written

$$\frac{du}{dt}-2v\zeta+2w\eta+\frac{dH}{dx}=0, \qquad (4)$$

$$\frac{dv}{dt}-2w\xi+2u\zeta+\frac{dH}{dy}=0, \qquad (5)$$

$$\frac{dw}{dt}-2u\eta+2v\xi+\frac{dH}{dz}=0, \qquad (6)$$

where

$$H=\int dp/\rho+V+\tfrac{1}{2}q^2, \qquad (7)$$

$$q^2=u^2+v^2+w^2, \qquad (8)$$

and the three terms in H may be called the pressure head, potential head, and head of velocity, when the gravitation unit is employed and $\frac{1}{2}q^2$ is replaced by $\frac{1}{2}q^2/g$.

Eliminating H between (5) and (6)

$$\frac{D\xi}{dt}-\xi\frac{du}{dx}-\eta\frac{dv}{dx}-\zeta\frac{dw}{dx}+\xi\left(\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}\right)=0, \qquad (9)$$

and combining this with the equation of continuity

$$\frac{1}{\rho}\frac{D\rho}{dt}+\frac{du}{dx}+\frac{dv}{dy}+\frac{dw}{dz}=0, \qquad (10)$$

we have

$$\frac{D}{dt}\left(\frac{\xi}{\rho}\right)-\frac{\xi}{\rho}\frac{du}{dx}-\frac{\eta}{\rho}\frac{dv}{dx}-\frac{\zeta}{\rho}\frac{dw}{dx}=0, \qquad (11)$$

with two similar equations.

Putting

$$\omega^2=\xi^2+\eta^2+\zeta^2, \qquad (12)$$

a *vortex line* is defined to be such that the tangent is in the direction of ω, the resultant of ξ, η, ζ, called the components of molecular rotation. A small sphere of the fluid, if frozen suddenly, would retain this angular velocity.

If ω vanishes throughout the fluid at any instant, equation (11) shows that it will always be zero, and the fluid motion is then called *irrotational*; and a function ϕ exists, called the *velocity function*, such that

$$udx+vdy+wdz=-d\phi, \qquad (13)$$

and then the velocity in any direction is the space-decrease or downward gradient of ϕ.

25. But in the most general case it is possible to have three functions ϕ, ψ, m of x, y, z, such that

$$udx+vdy+wdz=-d\phi-md\psi, \qquad (1)$$

as A. Clebsch has shown, from purely analytical considerations (*Crelle*, lvi.); and then

$$\xi=\tfrac{1}{2}\frac{d(\psi, m)}{d(y, z)},\quad \eta=\tfrac{1}{2}\frac{d(\psi, m)}{d(z, x)},\quad \zeta=\tfrac{1}{2}\frac{d(\psi, m)}{d(x, y)}, \qquad (2)$$

and

$$\xi\frac{d\psi}{dx}+\eta\frac{d\psi}{dy}+\zeta\frac{d\psi}{dz}=0,\quad \xi\frac{dm}{dx}+\eta\frac{dm}{dy}+\zeta\frac{dm}{dz}=0, \qquad (3)$$

so that, at any instant, the surfaces over which ψ and m are constant intersect in the vortex lines.

Putting

$$H-\frac{d\phi}{dt}-m\frac{d\psi}{dt}=K, \qquad (4)$$

the equations of motion (4), (5), (6) § 24 can be written

$$\frac{dK}{dx}-2u\zeta+2w\eta-\frac{d(\psi, m)}{d(x, t)}=0, \ldots, \ldots ; \qquad (5)$$

and therefore

$$\xi\frac{dK}{dx}+\eta\frac{dK}{dy}+\zeta\frac{dK}{dz}=0. \qquad (6)$$

Equation (5) becomes, by a rearrangement,

$$\frac{dK}{dx}-\frac{d\psi}{dx}\left(\frac{dm}{dt}+u\frac{dm}{dx}+v\frac{dm}{dy}+w\frac{dm}{dz}\right)$$
$$+\frac{dm}{dx}\left(\frac{d\psi}{dt}+u\frac{d\psi}{dx}+v\frac{d\psi}{dy}+w\frac{d\psi}{dz}\right)=0, \ldots, \ldots, \qquad (7)$$

$$\frac{dK}{dx}-\frac{d\psi}{dx}\frac{Dm}{dt}+\frac{dm}{dx}\frac{D\psi}{dt}=0, \ldots, \ldots, \qquad (8)$$

and as we prove subsequently (§ 37) that the vortex lines are composed of the same fluid particles throughout the motion, the surface m and ψ satisfies the condition of (6) § 23; so that K is uniform throughout the fluid at any instant, and changes with the time only, and so may be replaced by $F(t)$.

26. When the motion is *steady*, that is, when the velocity at any point of space does not change with the time,

$$\frac{dK}{dx}-2v\zeta+2w\eta=0, \ldots, \ldots \qquad (1)$$

$$\xi\frac{dK}{dx}+\eta\frac{dK}{dy}+\zeta\frac{dK}{dz}=0,\quad u\frac{dK}{dx}+v\frac{dK}{dy}+w\frac{dK}{dz}=0, \qquad (2)$$

and

$$K=\int dp/\rho+V+\tfrac{1}{2}q^2=H \qquad (3)$$

is constant along a vortex line, and a *stream line*, the path of a fluid particle, so that the fluid is traversed by a series of H surfaces, each covered by a network of stream lines and vortex lines; and if the motion is irrotational H is a constant throughout the fluid.

Taking the axis of x for an instant in the normal through a point on the surface H = constant, this makes $u=0$, $\xi=0$; and in steady motion the equations reduce to

$$dH/d\nu=2v\zeta-2w\eta=2q\omega\sin\theta, \qquad (4)$$

where θ is the angle between the stream line and vortex line; and this holds for their projection on any plane to which $d\nu$ is drawn perpendicular.

In plane motion (4) reduces to

$$\frac{dH}{d\nu}=2q\zeta=q\left(\frac{dq}{d\nu}+\frac{q}{r}\right), \qquad (5)$$

if r denotes the radius of curvature of the stream line, so that

$$\frac{1}{\rho}\frac{dp}{d\nu}+\frac{dV}{d\nu}=\frac{dH}{d\nu}-\frac{d\frac{1}{2}q^2}{d\nu}=\frac{q^2}{r}, \qquad (6)$$

the normal acceleration.

The osculating plane of a stream line in steady motion contains the resultant acceleration, the direction ratios of which are

$$u\frac{du}{dx}+v\frac{du}{dy}+w\frac{du}{dz}=\frac{d\frac{1}{2}q^2}{dx}-2v\zeta+2w\eta=\frac{d\frac{1}{2}q^2}{dx}-\frac{dH}{dx}, \ldots, \qquad (7)$$

and when q is stationary, the acceleration is normal to the surface H = constant, and the stream line is a geodesic.

Calling the sum of the pressure and potential head the statical head, surfaces of constant statical and dynamical head intersect in lines on H, and the three surfaces touch where the velocity is stationary.

Equation (3) is called Bernoulli's equation, and may be interpreted as the balance-sheet of the energy which enters and leaves a given tube of flow.

If homogeneous liquid is drawn off from a vessel so large that the motion at the free surface at a distance may be neglected, then Bernoulli's equation may be written

$$H=p/\rho+z+q^2/2g=P/\rho+h, \qquad (8)$$

where P denotes the atmospheric pressure and h the height of the free surface, a fundamental equation in hydraulics; a return has been made here to the gravitation unit of hydrostatics, and Oz is taken vertically upward.

In particular, for a jet issuing into the atmosphere, where $p=P$,

$$q^2/2g=h-z, \qquad (9)$$

or the velocity of the jet is due to the head $k-z$ of the still free surface above the orifice; this is Torricelli's theorem (1643), the foundation of the science of hydrodynamics.

27. *Uniplanar Motion.*—In the uniplanar motion of a homogeneous liquid the equation of continuity reduces to

$$\frac{du}{dx}+\frac{dv}{dy}=0, \qquad (1)$$

so that we can put

$$u=-d\psi/dy,\quad v=d\psi/dx, \qquad (2)$$

where ψ is a function of x, y, called the stream- or current-function; interpreted physically, $\psi-\psi_0$, the difference of the value of ψ at a fixed point A and a variable point P is the flow, in ft.³/ second, across any curved line AP from A to P, this being the same for all lines in accordance with the continuity.

Thus if $d\psi$ is the increase of ψ due to a displacement from P to P′, and k is the component of velocity normal to PP′, the flow across PP′ is $d\psi=k$.PP′; and taking PP′ parallel to Ox, $d\psi=vdx$; and similarly $d\psi=-udy$ with PP′ parallel to Oy; and generally $d\psi/ds$ is the velocity across ds, in a direction turned through a right angle forward, against the clock.

In the equations of uniplanar motion

$$2\zeta=\frac{dv}{dx}-\frac{du}{dy}=\frac{d^2\psi}{dx^2}+\frac{d^2\psi}{dy^2}=-\nabla^2\psi,\text{ suppose,}\tag{3}$$

so that in steady motion

$$\frac{dH}{dx}+\nabla^2\psi\frac{d\psi}{dx}=0,\ \frac{dH}{dy}+\nabla^2\psi\frac{d\psi}{dy}=0,\ \frac{dH}{d\psi}+\nabla^2\psi=0,\tag{4}$$

and $\nabla^2\psi$ must be a function of ψ.

If the motion is irrotational,

$$u=-\frac{d\phi}{dx}=-\frac{d\psi}{dy},\ v=-\frac{d\phi}{dy}=\frac{d\psi}{dx},\tag{5}$$

so that ψ and ϕ are conjugate functions of x and y,

$$\phi+\psi i=f(x+yi),\ \nabla^2\psi=0,\ \nabla^2\phi=0;\tag{6}$$

or putting

$$\phi+\psi i=w,\ x+yi=z,\ w=f(z).$$

The curves ϕ=constant and ψ=constant form an orthogonal system; and the interchange of ϕ and ψ will give a new state of uniplanar motion, in which the velocity at every point is turned through a right angle without alteration of magnitude.

For instance, in a uniplanar flow, radially inward towards O, the flow across any circle of radius r being the same and denoted by $2\pi m$, the velocity must be m/r, and

$$\phi=m\log r,\ \psi=m\theta,\ \phi+\psi i=m\log re^{i\theta},\ w=m\log z.\tag{7}$$

Interchanging these values

$$\psi=m\log r,\ \phi=m\theta,\ \psi+\phi i=m\log re^{i\theta}\tag{8}$$

gives a state of vortex motion, circulating round Oz, called a straight or columnar vortex.

A single vortex will remain at rest, and cause a velocity at any point inversely as the distance from the axis and perpendicular to its direction; analogous to the magnetic field of a straight electric current.

If other vortices are present, any one may be supposed to move with the velocity due to the others, the resultant stream function being

$$\psi=\Sigma m\log r=\log \Pi r^m;\tag{9}$$

the path of a vortex is obtained by equating the value of ψ at the vortex to a constant, omitting the r^m of the vortex itself.

When the liquid is bounded by a cylindrical surface, the motion of a vortex inside may be determined as due to a series of vortex-images, so arranged as to make the flow zero across the boundary.

For a plane boundary the image is the optical reflection of the vortex. For example, a pair of equal opposite vortices, moving on a line parallel to a plane boundary, will have a corresponding pair of images, forming a rectangle of vortices, and the path of a vortex will be the Cotes' spiral

$$r\sin 2\theta=2a,\text{ or } x^{-2}+y^{-2}=a^{-2};\tag{10}$$

this is therefore the path of a single vortex in a right-angled corner; and generally, if the angle of the corner is π/n, the path is the Cotes' spiral

$$r\sin n\theta=na.\tag{11}$$

A single vortex in a circular cylinder of radius a at a distance c from the centre will move with the velocity due to an equal opposite image at a distance a^2/c, and so describe a circle with velocity

$$mc/(a^2-c^2)\text{ in the periodic time } 2\pi(a^2-c^2)/m.\tag{12}$$

Conjugate functions can be employed also for the motion of liquid in a thin sheet between two concentric spherical surfaces; the components of velocity along the meridian and parallel in colatitude θ and longitude λ can be written

$$\frac{d\phi}{d\theta}=\frac{1}{\sin\theta}\frac{d\psi}{d\lambda},\ \frac{1}{\sin\theta}\frac{d\phi}{d\lambda}=-\frac{d\psi}{d\theta},\tag{13}$$

and then

$$\phi+\psi i=F(\tan\tfrac{1}{2}\theta.\,e^{\lambda i}).\tag{14}$$

28. *Uniplanar Motion of a Liquid due to the Passage of a Cylinder through it.*—A stream-function ψ must be determined to satisfy the conditions

$$\nabla^2\psi=0,\text{ throughout the liquid;}\tag{1}$$

$$\psi=\text{constant, over any fixed boundary;}\tag{2}$$

$$d\psi/ds=\text{normal velocity reversed over a solid boundary,}\tag{3}$$

so that, if the solid is moving with velocity U in the direction Ox, $d\psi/ds=-Udy/ds$, or $\psi+Uy$=constant over the moving cylinder; and $\psi+Uy=\psi'$ is the stream function of the relative motion of the liquid past the cylinder, and similarly $\psi-Vx$ for the component velocity V along Oy; and generally

$$\psi'=\psi+Uy-Vx\tag{4}$$

is the relative stream-function, constant over a solid boundary moving with components U and V of velocity.

If the liquid is stirred up by the rotation R of a cylindrical body,

$$d\psi/ds=\text{normal velocity reversed}$$

$$=-Rx\frac{dx}{ds}-Ry\frac{dy}{ds},\tag{5}$$

$$\psi+\tfrac{1}{2}R(x^2+y^2)=\psi',\tag{6}$$

a constant over the boundary; and ψ' is the current-function of the relative motion past the cylinder, but now

$$\nabla^2\psi'+2R=0,\tag{7}$$

throughout the liquid.

Inside an equilateral triangle, for instance, of height h,

$$\psi'=-2R\alpha\beta\gamma/h,\tag{8}$$

where α, β, γ are the perpendiculars on the sides of the triangle.

In the general case $\psi'=\psi+Uy-Vx+\frac{1}{2}R(x^2+y^2)$ is the relative stream function for velocity components, U, V, R.

29. *Example 1.*—Liquid motion past a circular cylinder.

Consider the motion given by

$$w=U(z+a^2/z),\tag{1}$$

so that

$$\phi=U\left(r+\frac{a^2}{r}\right)\cos\theta=U\left(1+\frac{a^2}{r^2}\right)x,\tag{2}$$

$$\psi=U\left(r-\frac{a^2}{r}\right)\sin\theta=U\left(1-\frac{a^2}{r^2}\right)y.$$

Then $\psi=0$ over the cylinder $r=a$, which may be considered a fixed post; and a stream line past it along which $\psi=Uc$, a constant, is the curve

$$\left(r-\frac{a^2}{r}\right)\sin\theta=c,\ (x^2+y^2)(y-c)-a^2y=0,\tag{3}$$

a cubic curve (C_3).

Over a concentric cylinder, external or internal, of radius $r=b$,

$$\psi'=\psi+U_1y=[U\left(1-\frac{a^2}{b^2}\right)+U_1]y,\tag{4}$$

and ψ' is zero if

$$U_1/U=(a^2-b^2)/b^2;\tag{5}$$

so that the cylinder may swim for an instant in the liquid without distortion, with this velocity U_1; and w in (1) will give the liquid motion in the interspace between the fixed cylinder $r=a$ and the concentric cylinder $r=b$, moving with velocity U_1.

When $b=0$, $U_1=\infty$; and when $b=\infty$, $U_1=-U$, so that at infinity the liquid is streaming in the direction xO with velocity U.

If the liquid is reduced to rest at infinity by the superposition of an opposite stream given by $w=-Uz$, we are left with

$$w=Ua^2/z,\tag{6}$$

$$\phi=U(a^2/r)\cos\theta=\ Ua^2x/(x^2+y^2),\tag{7}$$

$$\psi=-U(a^2/r)\sin\theta=-Ua^2y/(x^2+y^2),\tag{8}$$

giving the motion due to the passage of the cylinder $r=a$ with velocity U through the origin O in the direction Ox.

If the direction of motion makes an angle θ' with Ox,

$$\tan\theta'=\frac{d\phi}{dy}\Big/\frac{d\phi}{dx}=\frac{2xy}{x^2-y^2}=\tan 2\theta,\ \theta=\tfrac{1}{2}\theta',\tag{9}$$

and the velocity is Ua^2/r^2.

Along the path of a particle, defined by the C_3 of (3),

$$\sin^2\tfrac{1}{2}\theta'=\frac{y^2}{x^2+y^2}=\frac{y(y-c)}{a^2},\tag{10}$$

$$\tfrac{1}{2}\sin\theta'\frac{d\theta'}{ds}=\frac{2y-c}{a^2}\frac{dy}{ds},\tag{11}$$

on the radius of curvature is $\frac{1}{4}a^2/(y-\frac{1}{2}c)$, which shows that the curve is an Elastica or Lintearia. (J. C. Maxwell, *Collected Works*, ii. 208.)

If ϕ_1 denotes the velocity function of the liquid filling the cylinder $r=b$, and moving bodily with it with velocity U_1,

$$\phi_1=-U_1x,\tag{12}$$

and over the separating surface $r=b$

$$\frac{\phi}{\phi_1}=-\frac{U}{U_1}\left(1+\frac{a^2}{b^2}\right)=\frac{a^2+b^2}{a^2\sim b^2},\tag{13}$$

and this, by § 36, is also the ratio of the kinetic energy in the annular interspace between the two cylinders to the kinetic energy of the liquid moving bodily inside $r=b$.

Consequently the inertia to overcome in moving the cylinder $r=b$, solid or liquid, is its own inertia, increased by the inertia of liquid $(a^2+b^2)/(a^2\sim b^2)$ times the volume of the cylinder $r=b$; this total inertia is called the effective inertia of the cylinder $r=b$, at the instant the two cylinders are concentric.

With liquid of density ρ, this gives rise to a kinetic reaction to acceleration dU/dt, given by

$$\pi\rho b^2\frac{a^2+b^2}{a^2\sim b^2}\frac{dU}{dt}=\frac{a^2+b^2}{a^2\sim b^2}M'\frac{dU}{dt}, \tag{14}$$

if M′ denotes the mass of liquid displaced by unit length of the cylinder $r=b$. In particular, when $a=\infty$, the extra inertia is M′.

When the cylinder $r=a$ is moved with velocity U and $r=b$ with velocity U_1 along Ox,

$$\phi=\ U\frac{a^2}{b^2-a^2}\left(\frac{b^2}{r}+r\right)\cos\theta-U_1\frac{b^2}{b^2-a^2}\left(r+\frac{a^2}{r}\right)\cos\theta, \tag{15}$$

$$\psi=-U\frac{a^2}{b^2-a^2}\left(\frac{b^2}{r}-r\right)\sin\theta-U_1\frac{b^2}{b^2-a^2}\left(r-\frac{a^2}{r}\right)\sin\theta; \tag{16}$$

and similarly, with velocity components V and V_1 along Oy

$$\phi=\ V\frac{a^2}{b^2-a^2}\left(\frac{b^2}{r}+r\right)\sin\theta-V_1\frac{b^2}{b^2-a^2}\left(r+\frac{a^2}{r}\right)\sin\theta, \tag{17}$$

$$\psi=\ V\frac{a^2}{b^2-a^2}\left(\frac{b^2}{r}-r\right)\cos\theta+V_1\frac{b^2}{b^2-a^2}\left(r-\frac{a^2}{r}\right)\cos\theta; \tag{18}$$

and then for the resultant motion

$$w=\ (U^2+V^2)\frac{a^2}{b^2-a^2}\frac{z}{U+Vi}+\frac{a^2b^2}{b^2-a^2}\frac{U+Vi}{z}$$
$$-(U_1^2+V_1^2)\frac{b^2}{b^2-a^2}\frac{z}{U_1+V_1i}-\frac{a^2b^2}{b^2-a^2}\frac{U_1+V_1i}{z}. \tag{19}$$

The resultant impulse of the liquid on the cylinder is given by the component, over $r=a$ (§ 36),

$$X=\int\rho\phi\cos\theta.ad\theta=\pi\rho a^2\left(U\frac{b^2+a^2}{b^2-a^2}-U_1\frac{2b^2}{b^2-a^2}\right); \tag{20}$$

and over $r=b$

$$X_1=\int\rho\phi\cos\theta.bd\theta=\pi\rho b^2\left(U\frac{2a^2}{b^2-a^2}-U_1\frac{b^2+a^2}{b^2-a^2}\right), \tag{21}$$

and the difference $X-X_1$ is the component momentum of the liquid in the interspace; with similar expressions for Y and Y_1.

Then, if the outside cylinder is free to move

$$X_1=o,\ \frac{V_1}{U}=\frac{2a^2}{b^2+a^2},\quad X=\pi\rho a^2U\frac{b^2-a^2}{b^2+a^2}. \tag{22}$$

But if the outside cylinder is moved with velocity U_1, and the inside cylinder is solid or filled with liquid of density σ,

$$X=-\pi\sigma a^2U,\ \frac{U_1}{U}=\frac{2\rho b^2}{\rho(b^2+a^2)+\sigma(b^2-a^2)},$$
$$\frac{U-U_1}{U_1}=\frac{(\rho-\sigma)(b^2-a^2)}{\rho(b^2+a^2)+\sigma(b^2-a^2)}, \tag{23}$$

and the inside cylinder starts forward or backward with respect to the outside cylinder, according as $\rho >$ or $<\sigma$.

30. The expression for w in (1) § 29 may be increased by the addition of the term

$$im\log z=-m\theta+im\log r, \tag{1}$$

representing vortex motion circulating round the annulus of liquid.

Considered by itself, with the cylinders held fixed, the vortex sets up a circumferential velocity m/r on a radius r, so that the angular momentum of a circular filament of annular cross section dA is $\rho m dA$, and of the whole vortex is $\rho m\pi(b^2-a^2)$.

Any circular filament can be started from rest by the application of a circumferential impulse $\pi\rho m dr$ at each end of a diameter; so that a mechanism attached to the cylinders, which can set up a uniform distributed impulse $\pi\rho m$ across the two parts of a diameter in the liquid, will generate the vortex motion, and react on the cylinder with an impulse couple $-\rho m\pi a^2$ and $\rho m\pi b^2$, having resultant $\rho m\pi(b^2-a^2)$, and this couple is infinite when $b=\infty$, as the angular momentum of the vortex is infinite. Round the cylinder $r=a$ held fixed in the U current the liquid streams past with velocity

$$q'=2U\sin\theta+m/a; \tag{2}$$

and the loss of head due to this increase of velocity from U to q' is

$$\frac{q'^2-U^2}{2g}=\frac{(2U\sin\theta+m/a)^2-U^2}{2g}, \tag{3}$$

so that cavitation will take place, unless the head at a great distance exceeds this loss.

The resultant hydrostatic thrust across any diametral plane of the cylinder will be modified, but the only term in the loss of head which exerts a resultant thrust on the whole cylinder is $2mU\sin\theta/ga$, and its thrust is $2\pi\rho mU$ absolute units in the direction Cy, to be counteracted by a support at the centre C; the liquid is streaming past $r=a$ with velocity U reversed, and the cylinder is surrounded by a vortex. Similarly, the streaming velocity V reversed will give rise to a thrust $2\pi\rho mV$ in the direction xC.

Now if the cylinder is released, and the components U and V are reversed so as to become the velocity of the cylinder with respect to space filled with liquid, and at rest at infinity, the cylinder will experience components of force per unit length

(i.) $-2\pi\rho mV,\quad 2\pi\rho mU$, due to the vortex motion;

(ii.) $-\pi\rho a^2\frac{dU}{dt},\ -\pi\rho a^2\frac{dV}{dt}$, due to the kinetic reaction of the liquid;

(iii.) $o,\ -\pi(\sigma-\rho)a^2g$, due to gravity,

taking Oy vertically upward, and denoting the density of the cylinder by σ; so that the equations of motion are

$$\pi\sigma a^2\frac{dU}{dt}=-\pi\rho a^2\frac{dU}{dt}-2\pi\rho mV, \tag{4}$$

$$\pi\sigma a^2\frac{dV}{dt}=-\pi\rho a^2\frac{dV}{dt}+2\pi\rho mV-\pi(\sigma-\rho)a^2g, \tag{5}$$

or, putting $m=a^2\omega$, so that the vortex velocity is due to an angular velocity ω at a radius a,

$$(\sigma+\rho)dU/dt+2\rho\omega V=o, \tag{6}$$
$$(\sigma+\rho)dV/dt-2\rho\omega U+(\sigma-\rho)g=o. \tag{7}$$

Thus with $g=o$, the cylinder will describe a circle with angular velocity $2\rho\omega/(\sigma+\rho)$, so that the radius is $(\sigma+\rho)v/2\rho\omega$, if the velocity is v. With $\sigma=o$, the angular velocity of the cylinder is 2ω; in this way the velocity may be calculated of the propagation of ripples and waves on the surface of a vertical whirlpool in a sink.

Restoring σ will make the path of the cylinder a trochoid; and so the swerve can be explained of the ball in tennis, cricket, baseball, or golf.

Another explanation may be given of the sidelong force, arising from the velocity of liquid past a cylinder, which is encircled by a vortex. Taking two planes $x=\pm b$, and considering the increase of momentum in the liquid between them, due to the entry and exit of liquid momentum, the increase across dy in the direction Oy, due to elements at P and P′ at opposite ends of the diameter PP′, is

$$\rho dy\ (U-Ua^2r^{-2}\cos 2\theta+mr^{-1}\sin\theta)(Ua^2r^{-2}\sin 2\theta+mr^{-1}\cos\theta)$$
$$+\ \rho dy\ (-U+Ua^2r^{-2}\cos 2\theta+mr^{-1}\sin\theta)(Ua^2r^{-2}\sin 2\theta-mr^{-1}\cos\theta)$$
$$=2\rho dymUr^{-1}(\cos\theta-a^2r^{-2}\cos 3\theta), \tag{8}$$

and with $y=b\tan\theta$, $r=b\sec\theta$, this is

$$2\rho mUd\theta(1-a^2b^{-2}\cos 3\theta\cos\theta), \tag{9}$$

and integrating between the limits $\theta=\pm\frac{1}{2}\pi$, the resultant, as before, is $2\pi\rho mU$.

31. *Example 2.—Confocal Elliptic Cylinders.*—Employ the elliptic coordinates η, ξ, and $\zeta=\eta+\xi i$, such that

$$z=c\operatorname{ch}\zeta,\ x=c\operatorname{ch}\eta\cos\xi,\ y=c\operatorname{sh}\eta\sin\zeta; \tag{1}$$

then the curves for which η and ξ are constant are confocal ellipses and hyperbolas, and

$$J=\frac{d(x,y)}{d(\eta,\xi)}=c^2(\operatorname{ch}^2\eta-\cos^2\xi)$$
$$=\tfrac{1}{2}c^2(\operatorname{ch}2\eta-\cos 2\xi)=r_1r_2=OD^2, \tag{2}$$

if OD is the semi-diameter conjugate to OP, and r_1, r_2 the focal distances,

$$r_1,r_2=c(\operatorname{ch}\eta\pm\cos\xi); \tag{3}$$
$$r^2=x^2+y^2=c^2(\operatorname{ch}^2\eta-\sin^2\xi)$$
$$=\tfrac{1}{2}c^2(\operatorname{ch}2\eta+\cos 2\xi). \tag{4}$$

Consider the streaming motion given by

$$w=m\operatorname{ch}(\zeta-\gamma),\ \gamma=\alpha+\beta i, \tag{5}$$
$$\phi=m\operatorname{ch}(\eta-\alpha)\cos(\xi-\beta),\quad \psi=m\operatorname{sh}(\eta-\alpha)\sin(\xi-\beta). \tag{6}$$

Then $\psi=o$ over the ellipse $\eta=\alpha$, and the hyperbola $\xi=\beta$, so that these may be taken as fixed boundaries; and ψ is a constant on a C_4.

Over any ellipse η, moving with components U and V of velocity,

$$\psi'=\psi+Uy-Vx=[m\operatorname{sh}(\eta-\alpha)\cos\beta+Uc\operatorname{sh}\eta]\sin\xi$$
$$-[m\operatorname{sh}(\eta-\alpha)\sin\beta+Vc\operatorname{ch}\eta]\cos\xi; \tag{7}$$

so that $\psi'=o$, if

$$U=-\frac{m}{c}\frac{\operatorname{sh}(\eta-\alpha)}{\operatorname{sh}\eta}\cos\beta,\ V=-\frac{m}{c}\frac{\operatorname{sh}(\eta-\alpha)}{\operatorname{ch}\eta}\sin\beta, \tag{8}$$

having a resultant in the direction PO, where P is the intersection of an ellipse η with the hyperbola β; and with this velocity the ellipse η can be swimming in the liquid, without distortion for an instant.

At infinity

$$U=-\frac{m}{c}e^{-\alpha}\cos\beta=-\frac{m}{a-b}\cos\beta,$$

$$V=-\frac{m}{c}e^{-\alpha}\sin\beta=-\frac{m}{a+b}\sin\beta, \tag{9}$$

a and b denoting the semi-axes of the ellipse α; so that the liquid is streaming at infinity with velocity $Q=m/(a+b)$ in the direction of the asymptote of the hyperbola β.

An ellipse interior to $\eta=\alpha$ will move in a direction opposite to the exterior current; and when $\eta=o$, $U=\infty$, but $V=(m/c)\operatorname{sh}\alpha\sin\beta$.

Negative values of η must be interpreted by a streaming motion on a parallel plane at a level slightly different, as on a double Riemann sheet, the stream passing from one sheet to the other across a cut SS′ joining the foci S, S′. A diagram has been drawn by Col. R. L. Hippisley.

The components of the liquid velocity q, in the direction of the normal of the ellipse η and hyperbola ξ, are

$$-m\mathrm{J}^{-1}\,\mathrm{sh}(\eta-\alpha)\cos(\xi-\beta),\ m\mathrm{J}^{-1}\mathrm{ch}(\eta-\alpha)\sin(\xi-\beta). \tag{10}$$

The velocity q is zero in a corner where the hyperbola β cuts the ellipse α; and round the ellipse α the velocity q reaches a maximum when the tangent has turned through a right angle, and then

$$q=\mathrm{Q}e^{\alpha}\frac{\sqrt{(\mathrm{ch}\,2\alpha-\cos 2\beta)}}{\mathrm{sh}\,2\alpha}; \tag{11}$$

and the condition can be inferred when cavitation begins.

With $\beta=0$, the stream is parallel to xo, and

$$\phi=m\,\mathrm{ch}(\eta-\alpha)\cos\xi$$
$$=-\mathrm{U}c\,\mathrm{ch}(\eta-\alpha)\mathrm{sh}\,\eta\cos\xi/\mathrm{sh}(\eta-\alpha) \tag{12}$$

over the cylinder η, and as in (12) § 29,

$$\phi_1=-\mathrm{U}x=-\mathrm{U}c\,\mathrm{ch}\,\eta\cos\xi, \tag{13}$$

for liquid filling the cylinder; and

$$\frac{\phi}{\phi_1}=\frac{\mathrm{th}\,\eta}{\mathrm{th}\,(\eta-\alpha)}, \tag{14}$$

over the surface of η; so that parallel to Ox, the effective inertia of the cylinder η, displacing M′ liquid, is increased by $\mathrm{M}'\mathrm{th}\,\eta/\mathrm{th}(\eta-\alpha)$, reducing when $\alpha=\infty$ to $\mathrm{M}'\,\mathrm{th}\,\eta=\mathrm{M}'(b/a)$.

Similarly, parallel to Oy, the increase of effective inertia is $\mathrm{M}'/\mathrm{th}\,\eta\;\mathrm{th}(\eta-\alpha)$, reducing to $\mathrm{M}'/\mathrm{th}\,\eta=\mathrm{M}'(a/b)$, when $\alpha=\infty$, and the liquid extends to infinity.

32. Next consider the motion given by

$$\phi=m\,\mathrm{ch}\,2(\eta-\alpha)\sin 2\xi,\ \psi=-m\,\mathrm{sh}\,2(\eta-\alpha)\cos 2\xi; \tag{1}$$

in which $\psi=0$ over the ellipse α, and

$$\psi'=\psi+\tfrac{1}{2}\mathrm{R}(x^2+y^2)$$
$$=[-m\,\mathrm{sh}\,2(\eta-\alpha)+\tfrac{1}{4}\mathrm{R}c^2]\cos 2\xi+\tfrac{1}{4}\mathrm{R}c^2\,\mathrm{ch}\,2\eta, \tag{2}$$

which is constant over the ellipse η if

$$\tfrac{1}{4}\mathrm{R}c^2=m\,\mathrm{sh}\,2(\eta-\alpha); \tag{3}$$

so that this ellipse can be rotating with this angular velocity R for an instant without distortion, the ellipse α being fixed.

For the liquid filling the interior of a rotating elliptic cylinder of cross section

$$x^2/a^2+y^2/b^2=1, \tag{4}$$
$$\psi_1'=m_1(x^2/a^2+y^2/b^2) \tag{5}$$

with

$$\nabla^2\psi_1'=-2\mathrm{R}=-2m_1(1/a^2+1/b^2),$$
$$\psi_1=m_1(x^2/a^2+y^2/b^2)-\tfrac{1}{2}\mathrm{R}(x^2+y^2)$$
$$=-\tfrac{1}{2}\mathrm{R}(x^2-y^2)(a^2-b^2)/(a^2+b^2), \tag{6}$$
$$\phi_1=\mathrm{R}xy(a^2-b^2)/(a^2+b^2),$$
$$w_1=\phi_1+\psi_1 i=-\tfrac{1}{2}i\mathrm{R}(x+yi)^2(a^2-b^2)/(a^2+b^2).$$

The velocity of a liquid particle is thus $(a^2-b^2)/(a^2+b^2)$ of what it would be if the liquid was frozen and rotating bodily with the ellipse; and so the effective angular inertia of the liquid is $(a^2-b^2)^2/(a^2+b^2)^2$ of the solid; and the effective radius of gyration, solid and liquid, is given by

$$k^2=\tfrac{1}{4}(a^2+b^2),\ \text{and}\ \tfrac{1}{4}(a^2-b^2)^2/(a^2+b^2). \tag{7}$$

For the liquid in the interspace between α and η,

$$\frac{\phi}{\phi_1}=\frac{m\,\mathrm{ch}\,2(\eta-\alpha)\sin 2\xi}{\tfrac{1}{4}\mathrm{R}c^2\,\mathrm{sh}\,2\eta\sin 2\xi(a^2-b^2)/(a^2+b^2)}$$
$$=1/\mathrm{th}\,2(\eta-\alpha)\mathrm{th}\,2\eta; \tag{8}$$

and the effective k^2 of the liquid is reduced to

$$\tfrac{1}{4}c^2/\mathrm{th}\,2(\eta-\alpha)\mathrm{sh}\,2\eta, \tag{9}$$

which becomes $\tfrac{1}{4}c^2/\mathrm{sh}\,2\eta=\tfrac{1}{8}(a^2-b^2)/ab$, when $\alpha=\infty$, and the liquid surrounds the ellipse η to infinity.

An angular velocity R, which gives components $-\mathrm{R}y$, $\mathrm{R}x$ of velocity to a body, can be resolved into two shearing velocities, $-\mathrm{R}$ parallel to Ox, and R parallel to Oy; and then ψ is resolved into $\psi_1+\psi_2$, such that $\psi_1+\tfrac{1}{2}\mathrm{R}x^2$ and $\psi_2+\tfrac{1}{2}\mathrm{R}y^2$ is constant over the boundary.

Inside a cylinder

$$\phi_1+\psi_1 i=-\tfrac{1}{2}i\mathrm{R}(x+yi)^2a^2/(a^2+b^2), \tag{10}$$
$$\phi_2+\psi_2 i=\ \tfrac{1}{2}i\mathrm{R}(x+yi)^2b^2/(a^2+b^2), \tag{11}$$

and for the interspace, the ellipse α being fixed, and α_1 revolving with angular velocity R

$$\phi_1+\psi_1 i=-\tfrac{1}{8}i\mathrm{R}c^2\mathrm{sh}\,2(\eta-\alpha+\xi i)(\mathrm{ch}\,2\alpha+1)/\mathrm{sh}\,2(\alpha_1-\alpha), \tag{12}$$
$$\phi_2+\psi_2 i=\ \tfrac{1}{8}i\mathrm{R}c^2\mathrm{sh}\,2(\eta-\alpha+\xi i)(\mathrm{ch}\,2\alpha-1)/\mathrm{sh}\,2(\alpha_1-\alpha), \tag{13}$$

satisfying the condition that ψ_1 and ψ_2 are zero over $\eta=\alpha$, and over $\eta=\alpha_1$

$$\psi_1+\tfrac{1}{2}\mathrm{R}x^2=\tfrac{1}{8}\mathrm{R}c^2(\mathrm{ch}\,2\alpha_1+1), \tag{14}$$
$$\psi_2+\tfrac{1}{2}\mathrm{R}y^2=\tfrac{1}{8}\mathrm{R}c^2(\mathrm{ch}\,2\alpha_1-1), \tag{15}$$

constant values.

In a similar way the more general state of motion may be analysed, given by

$$w=m\,\mathrm{ch}\,2(\zeta-\gamma),\ \gamma=\alpha+\beta i, \tag{16}$$

as giving a homogeneous strain velocity to the confocal system; to which may be added a circulation, represented by an additional term $m\zeta$ in w.

Similarly, with

$$x+yi=c\sqrt{[\sin(\xi+\eta i)]} \tag{17}$$

the function

$$\psi=\mathrm{Q}c\,\mathrm{sh}\tfrac{1}{2}(\eta-\alpha)\sin\tfrac{1}{2}(\xi-\beta) \tag{18}$$

will give motion streaming past the fixed cylinder $\eta=\alpha$, and dividing along $\xi=\beta$; and then

$$x^2-y^2=c^2\sin\xi\,\mathrm{ch}\,\eta,\ 2xy=c^2\cos\xi\,\mathrm{sh}\,\eta. \tag{19}$$

In particular, with $\mathrm{sh}\,\alpha=1$, the cross-section of $\eta=\alpha$ is

$$x^4+6x^2y^2+y^4=2c^4,\ \text{or}\ x^4+y^4=c^4 \tag{20}$$

when the axes are turned through 45°.

33. *Example 3.*—Analysing in this way the rotation of a rectangle filled with liquid into the two components of shear, the stream function ψ_1 is to be made to satisfy the conditions

(i.) $\nabla^2\psi_1=0$,
(ii.) $\psi_1+\tfrac{1}{2}\mathrm{R}x^2=\tfrac{1}{2}\mathrm{R}a^2$, or $\psi_1=0$ when $x=\pm a$,
(iii.) $\psi_1+\tfrac{1}{2}\mathrm{R}x^2=\tfrac{1}{2}\mathrm{R}a^2$, $\psi_1=\tfrac{1}{2}\mathrm{R}(a^2-x^2)$, when $y=\pm b$

Expanded in a Fourier series,

$$a^2-x^2=\frac{32}{\pi^3}a^2\sum\frac{\cos(2n+1)\tfrac{1}{2}\pi x/a}{(2n+1)^3}, \tag{1}$$

so that

$$\psi_1=\mathrm{R}\frac{16}{\pi^3}a^2\sum\frac{\cos(2n+1)\tfrac{1}{2}\pi x/a\,.\,\mathrm{ch}(2n+1)\tfrac{1}{2}\pi y/a}{(2n+1)^3\,.\,\mathrm{ch}(2n+1)\tfrac{1}{2}\pi b/a},$$
$$w_1=\phi_1+\psi_1 i=i\mathrm{R}\frac{16}{\pi^3}a^2\sum\frac{\cos(2n+1)\tfrac{1}{2}\pi z/a}{(2n+1)^3\mathrm{ch}(2n+1)\tfrac{1}{2}\pi b/a}, \tag{2}$$

an elliptic-function Fourier series; with a similar expression for ψ_2 with x and y, a and b interchanged; and thence $\psi=\psi_1+\psi_2$.

Example 4.—Parabolic cylinder, axial advance, and liquid streaming past.

The polar equation of the cross-section being

$$r^{\frac{1}{2}}\cos\tfrac{1}{2}\theta=a^{\frac{1}{2}},\ \text{or}\ r+x=2a, \tag{3}$$

the conditions are satisfied by

$$\psi'=\mathrm{U}r\sin\theta-2\mathrm{U}a^{\frac{1}{2}}r^{\frac{1}{2}}\sin\tfrac{1}{2}\theta=2\mathrm{U}r^{\frac{1}{2}}\sin\tfrac{1}{2}\theta(r^{\frac{1}{2}}\cos\tfrac{1}{2}\theta-a^{\frac{1}{2}}), \tag{4}$$
$$\psi=2\mathrm{U}a^{\frac{1}{2}}r^{\frac{1}{2}}\sin\tfrac{1}{2}\theta=-\mathrm{U}\sqrt{[2a(r-x)]}, \tag{5}$$
$$w=-2\mathrm{U}a^{\frac{1}{2}}z^{\frac{1}{2}}, \tag{6}$$

and the resistance of the liquid is $2\pi\rho a\mathrm{V}^2/2g$.

A relative stream line, along which $\psi'=\mathrm{U}c$, is the quartic curve

$$y-c=\sqrt{[2a(r-x)]},\quad x=\frac{4a^2y^2-(y-c)^4}{4a(y-c)^2},\ r=\frac{4a^2y^2+(y-c)^4}{4a(y-c)^2}, \tag{7}$$

and in the absolute space curve given by ψ,

$$\frac{dy}{dx}=-\frac{(y-c)^2}{2ay},\ x=\frac{2ac}{y-c}-2a\log(y-c). \tag{8}$$

34. *Motion symmetrical about an Axis.*—When the motion of a liquid is the same for any plane passing through Ox, and lies in the plane, a function ψ can be found analogous to that employed in plane motion, such that the flux across the surface generated by the revolution of any curve AP from A to P is the same, and represented by $2\pi(\psi-\psi_0)$; and, as before, if $d\psi$ is the increase in ψ due to a displacement of P to P′, then k the component of velocity normal to the surface swept out by PP′ is such that $2\pi d\psi=2\pi yk.\mathrm{PP}'$; and taking PP′ parallel to Oy and Ox,

$$u=-d\psi/ydy,\ v=d\psi/ydx, \tag{1}$$

and ψ is called after the inventor, "Stokes's stream or current function," as it is constant along a stream line (*Trans. Camb. Phil. Soc.*, 1842; "Stokes's Current Function," R. A. Sampson, *Phil. Trans.*, 1892); and $d\psi/yds$ is the component velocity across ds in a direction turned through a right angle forward.

In this symmetrical motion

$$\xi=0,\ \eta=0,\ 2\zeta=\frac{d}{dx}\left(\frac{1}{y}\frac{d\psi}{dx}\right)+\frac{d}{dy}\left(\frac{1}{y}\frac{d\psi}{dy}\right)$$
$$=\frac{1}{y}\left(\frac{d^2\psi}{dx^2}+\frac{d^2\psi}{dy^2}-\frac{1}{y}\frac{d\psi}{dy}\right)=-\frac{1}{y}\nabla^2\psi, \tag{2}$$

suppose; and in steady motion,

$$\frac{d\mathrm{H}}{dx}+\frac{1}{y^2}\frac{d\psi}{dx}\nabla^2\psi=0,\ \frac{d\mathrm{H}}{dy}+\frac{1}{y^2}\frac{d\psi}{dy}\nabla^2\psi=0, \tag{3}$$

so that

$$2\zeta/y=-y^{-2}\nabla^2\psi=d\mathrm{H}/d\psi \tag{4}$$

is a function of ψ, say $f'(\psi)$, and constant along a stream line;

$$d\mathrm{H}/d\nu=2q\zeta,\ \mathrm{H}-f(\psi)=\text{constant}, \tag{5}$$

throughout the liquid.

When the motion is irrotational,

$$\zeta=0,\quad u=-\frac{d\phi}{dx}=-\frac{1}{y}\frac{d\psi}{dy},\quad v=-\frac{d\phi}{dy}=\frac{1}{y}\frac{d\psi}{dx}, \tag{6}$$
$$\nabla^2\psi=0,\ \text{or}\ \frac{d^2\psi}{dx^2}+\frac{d^2\psi}{dy^2}-\frac{1}{y}\frac{d\psi}{dy}=0. \tag{7}$$

Changing to polar coordinates, $x=r\cos\theta$, $y=r\sin\theta$, the equation (2) becomes, with $\cos\theta=\mu$,

$$r^2\frac{d^2\psi}{dr^2}+(1-\mu^2)\frac{d^2\psi}{d\mu^2}=2\zeta r^3\sin\theta, \qquad (8)$$

of which a solution, when $\zeta=0$, is

$$\psi=\left(Ar^{n+1}+\frac{B}{r^n}\right)(1-\mu^2)\frac{dP_n}{d\mu}=\left(Ar^{n-1}+\frac{B}{r^{n+2}}\right)y^2\frac{dP_n}{d\mu}, \qquad (9)$$

$$\phi=\{(n+1)Ar^n-nBr^{-n-1}\}P_n, \qquad (10)$$

where P_n denotes the zonal harmonic of the nth order; also, in the exceptional case of

$$\psi=A_0\cos\theta,\ \phi=A_0/r;$$
$$\psi=B_0 r,\ \phi=-B_0\log\tan\tfrac{1}{2}\theta$$
$$=-\tfrac{1}{2}B_0\,\mathrm{sh}^{-1}x/y. \qquad (11)$$

Thus $\cos\theta$ is the Stokes' function of a point source at O, and PA – PB of a line source AB.

The stream function ψ of the liquid motion set up by the passage of a solid of revolution, moving with axial velocity U, is such that

$$\frac{1}{y}\frac{d\psi}{ds}=-U\frac{dy}{ds},\ \psi+\tfrac{1}{2}Uy^2=\text{constant}, \qquad (12)$$

over the surface of the solid; and ψ must be replaced by $\psi'=\psi+\frac{1}{2}Uy^2$ in the general equations of steady motion above to obtain the steady relative motion of the liquid past the solid.

For instance, with $n=1$ in equation (9), the relative stream function is obtained for a sphere of radius a, by making it

$$\psi'=\psi+\tfrac{1}{2}Uy^2=\tfrac{1}{2}U(r^2-a^3/r)\sin^2\theta,\ \psi=-\tfrac{1}{2}Ua^3\sin^2\theta/r; \qquad (13)$$

and then

$$\phi'=Ux(1+\tfrac{1}{2}a^3/r^3),\ \phi=\tfrac{1}{2}Ua^3\cos\theta/r^2, \qquad (14)$$

$$-\frac{d\phi}{dr}=U\frac{a^3}{r^3}\cos\theta,\ -\frac{d\phi}{rd\theta}=\tfrac{1}{2}U\frac{a^3}{r^3}\sin\theta, \qquad (15)$$

so that, if the direction of motion makes an angle ψ with Ox,

$$\tan(\psi-\theta)=\tfrac{1}{2}\tan\theta,\ \tan\psi=3\tan\theta/(2-\tan^2\theta). \qquad (16)$$

Along the path of a liquid particle ψ' is constant, and putting it equal to $\frac{1}{2}Uc^2$,

$$(r^2-a^3/r)\sin^2\theta=c^2,\ \sin^2\theta=c^2r/(r^3-a^3), \qquad (17)$$

the polar equation; or

$$y^2=c^2r^3/(r^3-a^3),\ r^3=a^3y^2/(y^2-c^2), \qquad (18)$$

a curve of the 10th degree (C_{10}).

In the absolute path in space

$$\cos\psi=(2-3\sin^2\theta)/\sqrt{(4-\sin^2\theta)},\ \text{and}\ \sin^3\theta=(y^3-c^2y)/a^3, \qquad (19)$$

which leads to no simple relation.

The velocity past the surface of the sphere is

$$\frac{1}{r\sin\theta}\frac{d\psi'}{dr}=\tfrac{1}{2}U\left(2r+\frac{a^3}{r^2}\right)\frac{\sin^2\theta}{r\sin\theta}=\tfrac{3}{2}U\sin\theta,\ \text{when}\ r=a; \qquad (20)$$

so that the loss of head is

$$(\tfrac{9}{4}\sin^2\theta-1)U^2/2g,\ \text{having a maximum}\ \tfrac{5}{4}U^2/2g, \qquad (21)$$

which must be less than the head at infinite distance to avoid cavitation at the surface of the sphere.

With $n=2$, a state of motion is given by

$$\psi=-\tfrac{1}{2}Uy^2a^4\mu/r^4,\ \psi'=\tfrac{1}{2}Uy^2(1-a^4\mu/r^4), \qquad (22)$$

$$\phi'=Ux+\phi,\ \phi=-\tfrac{1}{3}U(a^4/r^3)P_2,\ P_2=\tfrac{3}{2}\mu^2-\tfrac{1}{2}, \qquad (23)$$

representing a stream past the surface $r^4=a^4\mu$.

35. A circular vortex, such as a smoke ring, will set up motion symmetrical about an axis, and provide an illustration; a half vortex ring can be generated in water by drawing a semicircular blade a short distance forward, the tip of a spoon for instance. The vortex advances with a certain velocity; and if an equal circular vortex is generated coaxially with the first, the mutual influence can be observed. The first vortex dilates and moves slower, while the second contracts and shoots through the first; after which the motion is reversed periodically, as if in a game of leap-frog. Projected perpendicularly against a plane boundary, the motion is determined by an equal opposite vortex ring, the optical image; the vortex ring spreads out and moves more slowly as it approaches the wall; at the same time the molecular rotation, inversely as the cross-section of the vortex, is seen to increase. The analytical treatment of such vortex rings is the same as for the electro-magnetic effect of a current circulating in each ring.

36. *Irrotational Motion in General.*—Liquid originally at rest in a singly-connected space cannot be set in motion by a field of force due to a single-valued potential function; any motion set up in the liquid must be due to a movement of the boundary, and the motion will be irrotational; for any small spherical element of the liquid may be considered a smooth solid sphere for a moment, and the normal pressure of the surrounding liquid cannot impart to it any rotation.

The kinetic energy of the liquid inside a surface S due to the velocity function ϕ is given by

$$T=\tfrac{1}{2}\rho\iiint\left[\left(\frac{d\phi}{dx}\right)^2+\left(\frac{d\phi}{dy}\right)^2+\left(\frac{d\phi}{dz}\right)^2\right]dxdydz,$$
$$=\tfrac{1}{2}\rho\iint\phi\frac{d\phi}{d\nu}dS \qquad (1)$$

by Green's transformation, $d\nu$ denoting an elementary step along the normal to the exterior of the surface; so that $d\phi/d\nu=0$ over the surface makes $T=0$, and then

$$\left(\frac{d\phi}{dx}\right)^2+\left(\frac{d\phi}{dy}\right)^2+\left(\frac{d\phi}{dz}\right)^2=0,\ \frac{d\phi}{dx}=0,\ \frac{d\phi}{dy}=0,\ \frac{d\phi}{dz}=0. \qquad (2)$$

If the actual motion at any instant is supposed to be generated instantaneously from rest by the application of pressure impulse over the surface, or suddenly reduced to rest again, then, since no natural forces can act impulsively throughout the liquid, the pressure impulse ϖ satisfies the equations

$$\frac{1}{\rho}\frac{d\varpi}{dx}=-u,\ \frac{1}{\rho}\frac{d\varpi}{dy}=-v,\ \frac{1}{\rho}\frac{d\varpi}{dz}=-\varpi, \qquad (3)$$

$$\varpi=\rho\phi+\text{a constant}, \qquad (4)$$

and the constant may be ignored; and Green's transformation of the energy T amounts to the theorem that the work done by an impulse is the product of the impulse and average velocity, or half the velocity from rest.

In a multiply connected space, like a ring, with a multiply valued velocity function ϕ, the liquid can circulate in the circuits independently of any motion of the surface; thus, for example,

$$\phi=m\theta=m\tan^{-1}y/x \qquad (5)$$

will give motion to the liquid, circulating in any ring-shaped figure of revolution round Oz.

To find the kinetic energy of such motion in a multiply connected space, the channels must be supposed barred, and the space made acyclic by a membrane, moving with the velocity of the liquid; and then if k denotes the cyclic constant of ϕ in any circuit, or the value by which ϕ has increased in completing the circuit, the values of ϕ on the two sides of the membrane are taken as differing by k, so that the integral over the membrane

$$\iint\phi\frac{d\phi}{d\nu}dS=k\iint\frac{d\phi}{d\nu}dS, \qquad (6)$$

and this term is to be added to the terms in (1) to obtain the additional part in the kinetic energy; the continuity shows that the integral is independent of the shape of the barrier membrane, and its position. Thus, in (5), the cyclic constant $k=2\pi m$.

In plane motion the kinetic energy per unit length parallel to Oz

$$T=\tfrac{1}{2}\rho\iint\left[\left(\frac{d\phi}{dx}\right)^2+\left(\frac{d\phi}{dy}\right)^2\right]dxdy=\tfrac{1}{2}\rho\iint\left[\left(\frac{d\psi}{dx}\right)^2+\left(\frac{d\psi}{dy}\right)^2\right]dxdy$$
$$=\tfrac{1}{2}\rho\int\phi\frac{d\phi}{d\nu}ds=\tfrac{1}{2}\rho\int\psi\frac{d\psi}{d\nu}ds. \qquad (7)$$

For example, in the equilateral triangle of (8) § 28, referred to coordinate axes made by the base and height,

$$\psi'=-2R\alpha\beta\gamma/h=-\tfrac{1}{2}Ry[(h-y)^2-3x^2]/h \qquad (8)$$
$$\psi=\psi'-\tfrac{1}{2}R[(\tfrac{1}{3}h-y)^2+x^2]$$
$$=-\tfrac{1}{2}R[\tfrac{1}{9}h^3+\tfrac{1}{3}h^2y+h)x^2-y^2)-3x^2y+y^3]/h \qquad (9)$$

and over the base $y=0$,

$$dx/d\nu=-dx/dy=+\tfrac{1}{2}R(\tfrac{1}{3}h^2-3x^2)/h,\psi=-\tfrac{1}{2}R(\tfrac{1}{9}h^2+x^2). \qquad (10)$$

Integrating over the base, to obtain one-third of the kinetic energy T,

$$\tfrac{1}{3}T=\tfrac{1}{2}\rho\int_{-h/\sqrt{3}}^{h/\sqrt{3}}\tfrac{1}{4}R^2(3x^4-\tfrac{1}{27}h^4)dx/h$$
$$=\rho R^2h^4/135\sqrt{3} \qquad (11)$$

so that the effective k^2 of the liquid filling the triangle is given by

$$k^2=T/\tfrac{1}{2}\rho R^2A=2h^2/45$$
$$=\tfrac{2}{5}\ (\text{radius of the inscribed circle})^2, \qquad (12)$$

or two-fifths of the k^2 for the solid triangle.

Again, since

$$d\phi/d\nu=d\psi/ds,\ d\phi/ds=-d\psi/d\nu, \qquad (13)$$
$$T=\tfrac{1}{2}\rho\int\phi d\psi=-\tfrac{1}{2}\rho\int\psi d\phi. \qquad (14)$$

With the Stokes' function ψ for motion symmetrical about an axis.

$$T=\tfrac{1}{2}\rho\int\phi\frac{d\psi}{yds}2\pi yds=\pi\rho\int\phi d\psi. \qquad (15)$$

37. *Flow, Circulation, and Vortex Motion.*—The line integral of the tangential velocity along a curve from one point to another, defined by

$$\int\left(u\frac{dx}{ds}+v\frac{dy}{ds}+w\frac{dz}{ds}\right)ds=\int(udx+vdy+zdz), \qquad (1)$$

is called the "flux" along the curve from the first to the second point; and if the curve closes in on itself the line integral round the curve is called the "circulation" in the curve.

With a velocity function ϕ, the flow

$$-\int d\phi=\phi_1-\phi_2, \qquad (2)$$

so that the flow is independent of the curve for all curves mutually reconcilable; and the circulation round a closed curve is zero, if the curve can be reduced to a point without leaving a region for which ϕ is single valued.

If through every point of a small closed curve the vortex lines are drawn, a tube is obtained, and the fluid contained is called a *vortex filament*.

By analogy with the spin of a rigid body, the component spin of the fluid in any plane at a point is defined as the circulation round a small area in the plane enclosing the point, divided by twice the area. For in a rigid body, rotating about Oz with angular velocity ζ, the circulation round a curve in the plane xy is

$$\int \zeta \left(x\frac{dy}{ds} - y\frac{dx}{ds} \right) ds = \zeta \text{ times twice the area.} \tag{3}$$

In a fluid, the circulation round an elementary area $dxdy$ is equal to

$$udx + \left(v+\frac{dv}{dx}dx\right)dy - \left(u+\frac{du}{dy}dy\right)dx - vdy = \left(\frac{dv}{dx}-\frac{du}{dy}\right)dxdy, \tag{4}$$

so that the component spin is

$$\tfrac{1}{2}\left(\frac{dv}{dx}-\frac{du}{dy}\right) = \zeta, \tag{5}$$

in the previous notation of § 24; so also for the other two components ξ and η.

Since the circulation round any triangular area of given aspect is the sum of the circulation round the projections of the area on the coordinate planes, the composition of the components of spin, ξ, η, ζ, is according to the vector law. Hence in any infinitesimal part of the fluid the circulation is zero round every small plane curve passing through the vortex line; and consequently the circulation round any curve drawn on the surface of a vortex filament is zero.

If at any two points of a vortex line the cross-section ABC, A′B′C′ is drawn of the vortex filament, joined by the vortex line AA′, then, since the flow in AA′ is taken in opposite directions in the complete circuit ABC AA′B′C′ A′A, the resultant flow in AA′ cancels, and the circulation in ABC, A′B′C′ is the same; this is expressed by saying that at all points of a vortex filament ωa is constant where a is the cross-section of the filament and ω the resultant spin (W. K. Clifford, *Kinematic*, book iii.).

So far these theorems on vortex motion are kinematical; but introducing the equations of motion of § 22,

$$\frac{Du}{dt}+\frac{dQ}{dx}=0, \quad \frac{Dv}{dt}+\frac{dQ}{dy}=0, \quad \frac{Dw}{dt}+\frac{dQ}{dz}=0, \tag{6}$$

$$Q=\int dp/\rho+V, \tag{7}$$

and taking dx, dy, dz in the direction of u, v, w, and $dx: dy: dz=u: v: w$,

$$\frac{D}{dt}\left(udx+vdy+wdz\right) = \frac{Du}{dt}dx + u\frac{Ddx}{dt} + \dots$$
$$= -dQ+\tfrac{1}{2}dq^2, \tag{8}$$

and integrating round a closed curve

$$\frac{D}{dt}\int(udx+vdy+wdz)=0, \tag{9}$$

and the circulation in any circuit composed of the same fluid particles is constant; and if the motion is differential irrotational and due to a velocity function, the circulation is zero round all reconcilable paths. Interpreted dynamically the normal pressure of the surrounding fluid on a tube cannot create any circulation in the tube.

The circulation being always zero round a small plane curve passing through the axis of spin in vortical motion, it follows conversely that a vortex filament is composed always of the same fluid particles; and since the circulation round a cross-section of a vortex filament is constant, not changing with the time, it follows from the previous kinematical theorem that $a\omega$ is constant for all time, and the same for every cross-section of the vortex filament.

A vortex filament must close on itself, or end on a bounding surface, as seen when the tip of a spoon is drawn through the surface of water.

Denoting the cross-section a of a filament by dS and its mass by dm, the quantity $\omega d\mathrm{S}/dm$ is called the *vorticity*; this is the same at all points of a filament, and it does not change during the motion; and the vorticity is given by $\omega\cos\epsilon d\mathrm{S}/dm$, if dS is the oblique section of which the normal makes an angle ϵ with the filament, while the aggregate vorticity of a mass M inside a surface S is

$$M^{-1}\int\omega\cos\epsilon d\mathrm{S}.$$

Employing the equation of continuity when the liquid is homogeneous,

$$2\left(\frac{d\zeta}{dy}-\frac{d\eta}{dz}\right)=\nabla^2u, \dots, \dots, \quad \nabla^2=-\frac{d^2}{dx^2}-\frac{d^2}{dy^2}-\frac{d^2}{dz^2}, \tag{10}$$

which is expressed by

$$\nabla^2(u, v, w)=2\operatorname{curl}(\xi, \eta, \zeta), \quad (\xi, \eta, \zeta)=\tfrac{1}{2}\operatorname{curl}(u, v, w). \tag{11}$$

38. *Moving Axes in Hydrodynamics*.—In many problems, such as the motion of a solid in liquid, it is convenient to take coordinate axes fixed to the solid and moving with it as the movable trihedron frame of reference. The components of velocity of the moving origin are denoted by U, V, W, and the components of angular velocity of the frame of reference by P, Q, R; and then if u, v, w denote the components of fluid velocity in space, and u', v', w' the components relative to the axes at a point (x, y, z) fixed to the frame of reference, we have

$$\begin{aligned} u&=U+u'-yR+zQ,\\ v&=V+v'-zP+xR,\\ w&=W+w'-xQ+yP. \end{aligned} \tag{1}$$

Now if k denotes the component of absolute velocity in a direction fixed in space whose direction cosines are l, m, n,

$$k=lu+mv+nw; \tag{2}$$

and in the infinitesimal element of time dt, the coordinates of the fluid particle at (x, y, z) will have changed by $(u', v', w')dt$; so that

$$\begin{aligned}\frac{Dk}{dt}&=\frac{dl}{dt}u+\frac{dm}{dt}v+\frac{dn}{dt}w\\ &+l\left(\frac{du}{dt}+u'\frac{du}{dx}+v'\frac{du}{dy}+w'\frac{du}{dz}\right)\\ &+m\left(\frac{dv}{dt}+u'\frac{dv}{dx}+v'\frac{dv}{dy}+w'\frac{dv}{dz}\right)\\ &+n\left(\frac{dw}{dt}+u'\frac{dw}{dx}+v'\frac{dw}{dy}+w'\frac{dw}{dz}\right).\end{aligned} \tag{3}$$

But as l, m, n are the direction cosines of a line fixed in space,

$$\frac{dl}{dt}=mR-nQ, \frac{dm}{dt}=nP-lR, \frac{dn}{dt}=lQ-mP; \tag{4}$$

so that

$$\frac{Dk}{dt}=l\left(\frac{du}{dt}-vR+wQ+u'\frac{du}{dx}+v'\frac{du}{dy}+w'\frac{du}{dz}\right)+m(\dots)+n(\dots)$$
$$=l\left(X-\frac{1}{\rho}\frac{dp}{dx}\right)+m\left(Y-\frac{1}{\rho}\frac{dp}{dy}\right)+n\left(Z-\frac{1}{\rho}\frac{dp}{dz}\right), \tag{5}$$

for all values of l, m, n, leading to the equations of motion with moving axes.

When the motion is such that

$$u=-\frac{d\phi}{dx}-m\frac{d\psi}{dx}, \; v=-\frac{d\phi}{dy}-m\frac{d\psi}{dy}, \; w=-\frac{d\phi}{dz}-m\frac{d\psi}{dz}, \tag{6}$$

as in § 25 (1), a first integral of the equations in (5) may be written

$$\int\frac{dp}{\rho}+V+\tfrac{1}{2}q^2-\frac{d\phi}{dt}-m\frac{d\psi}{dt}+(u-u')\left(\frac{d\phi}{dx}+m\frac{d\psi}{dx}\right)$$
$$+(v-v')\left(\frac{d\phi}{dy}+m\frac{d\psi}{dy}\right)+(w-w')\left(\frac{d\phi}{dz}+m\frac{d\psi}{dz}\right)=F(t), \tag{7}$$

in which

$$\frac{d\phi}{dt}-(u-u')\frac{d\phi}{dx}-(v-v')\frac{d\phi}{dy}-(w-w')\frac{d\phi}{dz}$$
$$=\frac{d\phi}{dt}-(U-yR+zQ)\frac{d\phi}{dx}-(V-zP+xR)\frac{d\phi}{dy}-(W-xQ+yP)\frac{d\phi}{dz} \tag{8}$$

is the time-rate of change of ϕ at a point fixed in space, which is left behind with velocity components $u-u'$, $v-v'$, $w-w'$.

In the case of a steady motion of homogeneous liquid symmetrical about Ox, where O is advancing with velocity U, the equation (5) of § 34

$$p/\rho+V+\tfrac{1}{2}q'^2-f(\psi')=\text{constant} \tag{9}$$

becomes transformed into

$$\frac{p}{\rho}+V+\tfrac{1}{2}q^2-\frac{U}{y}\frac{d\psi}{dy}+\tfrac{1}{2}U^2-f(\psi+\tfrac{1}{2}Uy^2)=\text{constant}, \tag{10}$$

$$\psi'=\psi+\tfrac{1}{2}Uy^2, \tag{11}$$

subject to the condition, from (4) § 34,

$$y^{-2}\nabla^2\psi'=-f'(\psi'), \quad y^{-2}\nabla^2\psi=-f'(\psi+\tfrac{1}{2}Uy^2). \tag{12}$$

Thus, for example, with

$$\psi'=\tfrac{3}{4}Uy^2(r^2a^{-2}-1), \; r^2=x^2+y^2, \tag{13}$$

for the space inside the sphere $r=a$, compared with the value of ψ' in § 34 (13) for the space outside, there is no discontinuity of the velocity in crossing the surface.

Inside the sphere

$$2\zeta=\frac{d}{dx}\left(\frac{1}{y}\frac{d\psi'}{dx}\right)+\frac{d}{dy}\left(\frac{1}{y}\frac{d\psi'}{dy}\right)=\frac{15}{2}U\frac{y}{a^2}, \tag{14}$$

so that § 34 (4) is satisfied, with

$$f'(\psi')=\frac{15}{2}Ua^{-2}, \; f(\psi')=\frac{15}{2}U\psi'a^{-2}; \tag{15}$$

and (10) reduces to

$$\frac{p}{\rho}+V-\frac{9}{8}U\left\{\left(\frac{x^2}{a^2}-1\right)^2-\left(\frac{y^2}{a^2}-\tfrac{1}{2}\right)^2\right\}=\text{constant}; \tag{16}$$

this gives the state of motion in M. J. M. Hill's spherical vortex, advancing through the surrounding liquid with uniform velocity.

39. As an application of moving axes, consider the motion of liquid filling the ellipsoidal case

$$\frac{x^2}{a^2}+\frac{y^2}{b^2}+\frac{z^2}{c^2}=1; \tag{1}$$

and first suppose the liquid to be frozen, and the ellipsoid to be rotating about the centre with components of angular velocity ξ, η, ζ; then

$$u=-y\zeta+z\eta,\ v=-z\xi+x\zeta,\ w=-x\eta+y\xi. \qquad (2)$$

Now suppose the liquid to be melted, and additional components of angular velocity Ω_1, Ω_2, Ω_3 communicated to the ellipsoidal case; the additional velocity communicated to the liquid will be due to a velocity-function

$$\phi=-\Omega_1\frac{b^2-c^2}{b^2+c^2}yz-\Omega_2\frac{c^2-a^2}{c^2+a^2}zx-\Omega_3\frac{a^2-b^2}{a^2+b^2}xy, \qquad (3)$$

as may be verified by considering one term at a time.

If u', v', w' denote the components of the velocity of the liquid relative to the axes,

$$u'=u+y\mathrm{R}-z\mathrm{Q}=\frac{2a^2}{a^2+b^2}\Omega_3 y-\frac{2a^2}{c^2+a^2}\Omega_2 z, \qquad (4)$$

$$v'=v+z\mathrm{P}-x\mathrm{R}=\frac{2b^2}{b^2+c^2}\Omega_1 z-\frac{2b^2}{a^2+b^2}\Omega_3 x, \qquad (5)$$

$$w'=w+x\mathrm{Q}-y\mathrm{P}=\frac{2c^2}{c^2+a^2}\Omega_2 x-\frac{2c^2}{b^2+c^2}\Omega_1 y, \qquad (6)$$

$$\mathrm{P}=\Omega_1+\xi,\ \mathrm{Q}=\Omega_2+\eta,\ \mathrm{R}=\Omega_3+\zeta. \qquad (7)$$

Thus

$$u'\frac{x}{a_2}+v'\frac{y}{b_2}+w'\frac{z}{c_2}=0, \qquad (8)$$

so that a liquid particle remains always on a similar ellipsoid.

The hydrodynamical equations with moving axes, taking into account the mutual gravitation of the liquid, become

$$\frac{1}{\rho}\frac{dp}{dx}+4\pi\rho\mathrm{A}x+\frac{du}{dt}-v\mathrm{R}+w\mathrm{Q}+u'\frac{du}{dx}+v'\frac{du}{dy}+w'\frac{du}{dz}=0,\ldots\ldots, \qquad (9)$$

where

$$\mathrm{A,B,C,}=\int_0^\infty\frac{abcd\lambda}{(a^2+\lambda,\ b^2+\lambda,\ c^2+\lambda)\mathrm{P}}$$

$$\mathrm{P}^2=4(a^2+\lambda)(b^2+\lambda)(c^2+\lambda). \qquad (10)$$

With the values above of u, v, w, u', v', w', the equations become of the form

$$\frac{1}{\rho}\frac{dp}{dx}+4\pi\rho\mathrm{A}x+\alpha x+hy+gz=0, \qquad (11)$$

$$\frac{1}{\rho}\frac{dp}{dy}+4\pi\rho\mathrm{B}y+hx+\beta y+fz=0, \qquad (12)$$

$$\frac{1}{\rho}\frac{dp}{dz}+4\pi\rho\mathrm{C}z+gx+fy+\gamma z=0, \qquad (13)$$

and integrating

$$p\rho^{-1}+2\pi\rho(\mathrm{A}x^2+\mathrm{B}y^2+\mathrm{C}z^2)$$
$$+\tfrac{1}{2}(\alpha x^2+\beta y^2+\gamma z^2+2fyz+2gzx+2hxy)=\text{const.}, \qquad (14)$$

so that the surfaces of equal pressure are similar quadric surfaces, which, symmetry and dynamical considerations show, must be coaxial surfaces; and f, g, h vanish, as follows also by algebraical reduction; and

$$\alpha=\frac{4c^2(c^2-a^2)}{(c^2+a^2)^2}\Omega_2^2-\left(\frac{c^2-a^2}{c^2+a^2}\Omega_2-\eta\right)^2$$
$$-\frac{4b^2(a^2-b^2)}{(a^2+b^2)^2}\Omega_3^2-\left(\frac{a^2-b^2}{a^2+b^2}\Omega_3-\zeta\right)^2, \qquad (15)$$

with similar equations for β and γ.

If we can make

$$(4\pi\rho\mathrm{A}+\alpha)x^2=(4\pi\rho\mathrm{B}+\beta)b^2=(4\pi\rho\mathrm{C}+\gamma)c^2, \qquad (16)$$

the surfaces of equal pressure are similar to the external case, which can then be removed without affecting the motion, provided α, β, γ remain constant.

This is so when the axis of revolution is a principal axis, say Oz; when

$$\Omega_1=0,\ \Omega_2=0,\ \xi=0,\ \eta=0. \qquad (17)$$

If $\Omega_3=0$ or $\theta_3=\zeta$ in addition, we obtain the solution of Jacobi's ellipsoid of liquid of three unequal axes, rotating bodily about the least axis; and putting $a=b$, Maclaurin's solution is obtained of the rotating spheroid.

In the general motion again of the liquid filling a case, when $a=b$, Ω_3 may be replaced by zero, and the equations, hydrodynamical and dynamical, reduce to

$$\frac{d\xi}{dt}=-\frac{2c^2}{a^2+c^2}\Omega_2\zeta,\ \frac{d\eta}{dt}=\frac{2a^2}{a^2+c^2}\Omega_1\zeta,\ \frac{d\zeta}{dt}=\frac{2c^2}{a^2+c^2}(\Omega_2\xi-\Omega_1\eta) \qquad (18)$$

$$\frac{d\Omega_1}{dt}=\Omega_2\zeta+\frac{a^2+c^2}{a^2-c^2}\eta\zeta,\ \frac{d\Omega_2}{dt}=-\Omega_1\zeta-\frac{a^2+c^2}{a^2-c^2}\xi\zeta; \qquad (19)$$

of which three integrals are

$$\xi^2+\eta^2=\mathrm{L}-\frac{a^2}{c^2}\zeta^2, \qquad (20)$$

$$\Omega_1^2+\Omega_2^2=\mathrm{M}+\frac{(a^2+c^2)^2}{2c^2(a^2-c^2)}\zeta^2, \qquad (21)$$

$$\Omega_1\xi+\Omega_2\eta\mathrm{N}=+\frac{a^2+c^2}{4c^2}\zeta^2; \qquad (22)$$

and then

$$\left(\frac{d\zeta}{dt}\right)^2=\frac{4c^4}{(a^2+c^2)^2}(\Omega_2\xi-\Omega_1\eta)^2$$
$$=\frac{4c^4}{(a^2+c^2)^2}[(\xi^2+\eta^2)(\Omega_1^2+\Omega_2^2)-(\Omega_1\xi+\Omega_2\eta)^2]$$
$$=\frac{4c^4}{(a^2+c^2)^2}\left[\mathrm{LM}-\mathrm{N}^2+\left\{\mathrm{L}\frac{(a^2+c^2)^2}{2c^2(a^2-c^2)}-\mathrm{M}\frac{a^2}{c^2}-\mathrm{N}\frac{a^2+c^2}{2c^2}\right\}\zeta^2\right.$$
$$\left.-\frac{(a^2+c^2)(9a^2-c^2)}{16c^4(a^2-c^2)}\zeta^4\right]=\mathrm{Z}, \qquad (23)$$

where Z is a quadratic in ζ^2, so that ζ is an elliptic function of t, except when $c=a$, or $3a$.

Put $\Omega_1=\Omega\cos\phi$, $\Omega_2=-\Omega\sin\phi$,

$$\Omega_2\frac{d\phi}{dt}=\frac{d\Omega_1}{dt}\Omega_2-\Omega_1\frac{d\Omega_2}{dt}=\Omega^2\zeta-\frac{a^2+c^2}{a^2-c^2}(\Omega_1\xi+\Omega_2\eta)\zeta, \qquad (24)$$

$$\frac{d\phi}{dt}=\zeta-\frac{a^2+c^2}{a^2-c^2}\cdot\frac{\mathrm{N}+\frac{a^2+c^2}{4c^2}\zeta^2}{\mathrm{M}+\frac{(a^2+c^2)^2}{2c^2(a^2-c^2)}\zeta^2}, \qquad (25)$$

$$\phi=\int\frac{\zeta d\zeta}{\sqrt{\mathrm{Z}}}-\frac{a^2+c^2}{a^2-c^2}\int\frac{\mathrm{N}+\frac{a^2+c^2}{4c^2}\zeta^2}{\mathrm{M}+\frac{(a^2+c^2)^2}{2c^2(a^2-c^2)}\zeta^2}\cdot\frac{\zeta d\zeta}{\sqrt{\mathrm{Z}}}, \qquad (26)$$

which, as Z is a quadratic function of ζ^2, are non-elliptic integrals; so also for ψ, where $\xi=\omega\cos\psi$, $\eta=-\omega\sin\psi$.

In a state of steady motion

$$\frac{d\zeta}{dt}=0,\ \frac{\Omega_1}{\xi}=\frac{\Omega_2}{\eta}, \qquad (27)$$

$$\phi=\psi=nt,\ \text{suppose}, \qquad (28)$$

$$\Omega_1\xi+\Omega_2\eta=\Omega\omega, \qquad (29)$$

$$\frac{d\phi}{dt}=\zeta-\frac{a^2+c^2}{a^2-c^2}\frac{\omega}{\Omega}\zeta, \qquad (30)$$

$$\frac{d\psi}{dt}=-\frac{2a^2}{a^2+c^2}\frac{\Omega}{\omega}\zeta, \qquad (31)$$

$$1-\frac{a^2+c^2}{a^2-c^2}\frac{\omega}{\Omega}=-\frac{2a^2}{a^2+c^2}\frac{\Omega}{\omega}, \qquad (32)$$

$$\left(\frac{\omega}{\Omega}-\frac{1}{2}\frac{a^2-c^2}{a^2+c^2}\right)^2=\frac{(a^2-c^2)(9a^2-c^2)}{4(a^2+c^2)}, \qquad (33)$$

and a state of steady motion is impossible when $3a>c>a$.

An experiment was devised by Lord Kelvin for demonstrating this, in which the difference of steadiness was shown of a copper shell filled with liquid and spun gyroscopically, according as the shell was slightly oblate or prolate. According to the theory above the stability is regained when the length is more than three diameters, so that a modern projectile with a cavity more than three diameters long should fly steadily when filled with water; while the old-fashioned type, not so elongated, would be highly unsteady; and for the same reason the gas bags of a dirigible balloon should be over rather than under three diameters long.

40. *A Liquid Jet.*—By the use of the complex variable and its conjugate functions, an attempt can be made to give a mathematical interpretation of problems such as the efflux of water in a jet or of smoke from a chimney, the discharge through a weir, the flow of water through the piers of a bridge, or past the side of a ship, the wind blowing on a sail or aeroplane, or against a wall, or impinging jets of gas or water; cases where a surface of discontinuity is observable, more or less distinct, which separates the running stream from the dead water or air.

Uniplanar motion alone is so far amenable to analysis; the velocity function ϕ and stream function ψ are given as conjugate functions of the coördinates x, y by

$$w=f(z),\ \text{where}\ z=x+yi,\ w=\phi+\psi i, \qquad (1)$$

and then

$$\frac{dw}{dz}=\frac{d\phi}{dx}+i\frac{d\psi}{dx}=-u+vi; \qquad (2)$$

so that, with $u=q\cos\theta$, $v=q\sin\theta$, the function

$$\zeta=-\mathrm{Q}\frac{dz}{dw}=\frac{\mathrm{Q}}{u-vi}=\frac{\mathrm{Q}}{q^2}(u+vi)=\frac{\mathrm{Q}}{q}(\cos\ \theta+i\sin\theta), \qquad (3)$$

gives ζ as a vector representing the reciprocal of the velocity q in direction and magnitude, in terms of some standard velocity Q.

To determine the motion of a jet which issues from a vessel with plane walls, the vector ζ must be constructed so as to have a constant direction θ along a plane boundary, and to give a constant skin velocity over the surface of a jet, where the pressure is constant.

It is convenient to introduce the function

$$\Omega=\log\zeta=\log(Q/q)+\theta i \qquad (4)$$

so that the polygon representing Ω conformally has a boundary given by straight lines parallel to the coordinate axes; and then to determine Ω and w as functions of a variable u (not to be confused with the velocity component of q), such that in the conformal representation the boundary of the Ω and w polygon is made to coincide with the real axis of u.

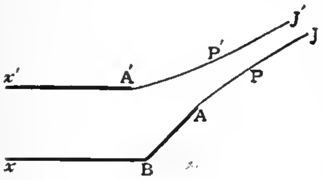

FIG. 4.

It will be sufficient to give a few illustrations.

Consider the motion where the liquid is coming from an infinite distance between two parallel walls at a distance xx' (fig. 4), and issues in a jet between two edges A and A'; the wall xA being bent at a corner B, with the external angle $\beta=\frac{1}{2}\pi/n$.

The theory of conformal representation shows that the motion is given by

$$\zeta=\left[\frac{\sqrt{(b-a'.u-a)}+\sqrt{(b-a.u-a')}}{\sqrt{(a-a'.u-b)}}\right]^{1/n},\quad u=ae^{-\pi w/m}; \quad (5)$$

where $u=a$, a' at the edge A, A[1]; $u=b$ at a corner B; $u=0$ across xx' where $\phi=\infty$; and $u=\infty$, $\phi=\infty$ across the end JJ' of the jet, bounded by the curved lines APJ, A'P'J', over which the skin velocity is Q. The stream lines xBAJ, xA'J' are given by $\psi=0$, m; so that if c denotes the ultimate breadth JJ' of the jet, where the velocity may be supposed uniform and equal to the skin velocity Q,

$$m=Qc,\quad c=m/Q.$$

If there are more B corners than one, either on xA or x'A', the expression for ζ is the product of corresponding factors, such as in (5).

Restricting the attention to a single corner B,

$$\zeta^n=\left(\frac{Q}{q}\right)^n(\cos n\theta+i\sin n\theta)=\frac{\sqrt{(b-a'.u-a)}+\sqrt{(b-a.u-a')}}{\sqrt{(a-a'.u-b)}}, \quad (6)$$

$$\text{ch}\, n\Omega=\text{ch}\log\left(\frac{Q}{q}\right)^n\cos n\theta+i\,\text{sh}\log\left(\frac{Q}{q}\right)^n\sin n\theta$$

$$=\tfrac{1}{2}(\zeta^n+\zeta^{-n})=\sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{u-a}{u-b}}, \quad (7)$$

$$\text{sh}\, n\Omega=\text{sh}\log\left(\frac{Q}{q}\right)\cos n\theta+i\,\text{ch}\log\left(\frac{Q}{q}\right)^n\sin n\theta$$

$$=\tfrac{1}{2}(\zeta^n-\zeta^{-n})=\sqrt{\frac{b-a}{a-a'}}\sqrt{\frac{u-a'}{u-b}}, \quad (8)$$

$$\infty>a>b>0>a'>-\infty; \quad (9)$$

and then

$$\frac{d\Omega}{du}=-\frac{1}{2n}\frac{\sqrt{(b-a.b-a')}}{(u-b)\sqrt{(u-a.u-a')}},\ \frac{dw}{du}=-\frac{m}{\pi u}, \quad (10)$$

the formulas by which the conformal representation is obtained.

For the Ω polygon has a right angle at $u=a$, a', and a zero angle at $u=b$, where θ changes from 0 to $\frac{1}{2}\pi/n$ and Ω increases by $\frac{1}{2}i\pi/n$; so that

$$\frac{d\Omega}{du}=\frac{A}{(u-b)\sqrt{(u-a.u-a')}},\ \text{where } A=-\frac{\sqrt{(b-a.b-a')}}{2n}. \quad (11)$$

And the w polygon has a zero angle at $u=0$, ∞, where ψ changes from 0 to m and back again, so that w changes by im, and

$$\frac{dw}{du}=\frac{B}{u},\ \text{where } B=-\frac{m}{\pi}. \quad (12)$$

Along the stream line xBAPJ,

$$\psi=0,\quad u=ae^{-\pi\phi/m}; \quad (13)$$

and over the jet surface JPA, where the skin velocity is Q,

$$\frac{d\phi}{ds}=-q=-Q,\quad u=ae^{\pi sQ/m}=ae^{\pi s/c}, \quad (14)$$

denoting the arc AP by s, starting at $u=a$;

$$\text{ch}\, n\Omega=\cos n\theta=\sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{u-a}{u-b}}, \quad (15)$$

$$\text{sh}\, n\Omega=i\sin n\theta=i\sqrt{\frac{a-b}{a-a'}}\sqrt{\frac{u-a'}{u-b}}, \quad (16)$$

$$\infty>u=ae^{\pi s/c}>a, \quad (17)$$

and this gives the intrinsic equation of the jet, and then the radius of curvature

$$\rho=-\frac{ds}{d\theta}=\frac{1}{Q}\frac{d\phi}{d\theta}=\frac{i}{Q}\frac{dw}{d\Omega}=\frac{i}{Q}\frac{dw}{du}\Big/\frac{d\Omega}{du}$$

$$=\frac{c}{\pi}.2n\frac{u-b}{u}\frac{\sqrt{(u-a.u-a')}}{\sqrt{(a-b.b-a')}}, \quad (18)$$

not requiring the integration of (11) and (12)

If $\theta=\alpha$ across the end JJ' of the jet, where $u=\infty$, $q=Q$,

$$\text{ch}\, n\Omega=\cos n\alpha=\sqrt{\frac{b-a'}{a-a'}},\ \text{sh}\, n\Omega=i\sin n\alpha=i\sqrt{\frac{a-b}{a-a'}}, \quad (19)$$

Then

$$\cos 2n\alpha-\cos 2n\theta=2\frac{a-b.b-a'}{a-a'.u-b}=\tfrac{1}{2}\sin^2 2n\alpha\frac{a-a'}{u-b}$$

$$\sin 2n\theta=2\frac{\sqrt{(a-b.b-a')}\sqrt{(u-a.u-b')}}{a-a'.u-b} \quad (20)$$

$$=\sin 2n\alpha\frac{\sqrt{(u-a.u-a')}}{u-b};$$

$$\frac{2n}{\pi}\frac{c}{\rho}=\left(1+\frac{b}{u-b}\right)\frac{\sqrt{(a-b.b-a')}}{\sqrt{(u-a.u-a')}} \quad (21)$$

$$=\frac{a-a'+(a+a')\cos 2n\alpha-[a+a'+(a-a')\cos 2n\alpha]\cos 2n\theta}{(a-a')\sin^2 2n\alpha}$$

$$\times\frac{\cos 2n\alpha-\cos 2n\theta}{\sin 2n\theta}.$$

Along the wall AB, $\cos n\theta=0$, $\sin n\theta=1$,

$$a>u>b, \quad (22)$$

$$\text{ch}\, n\Omega=i\,\text{sh}\log\left(\frac{Q}{q}\right)^n=i\sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{a-u}{u-b}}, \quad (23)$$

$$\text{sh}\, n\Omega=i\,\text{ch}\log\left(\frac{Q}{q}\right)^n=i\sqrt{\frac{a-b}{a-a'}}\sqrt{\frac{u-a'}{u-b}}, \quad (24)$$

$$\frac{ds}{du}=\frac{ds}{d\phi}\frac{d\phi}{dt}=\frac{m}{\pi qu}=\frac{c}{\pi}\frac{Q}{qu} \quad (25)$$

$$\pi\frac{AB}{c}=\int_b^a\frac{Q}{q}\frac{du}{u}$$

$$=\int\left[\frac{\sqrt{(a-b)}\sqrt{(u-a')}+\sqrt{(b-a')}\sqrt{(a-u)}}{\sqrt{(a-a')}\sqrt{(u-b)}}\right]^{1/n}\frac{du}{u}. \quad (26)$$

Along the wall Bx, $\cos n\theta=1$, $\sin n\theta=0$,

$$b>u>0 \quad (27)$$

$$\text{ch}\, n\Omega=\text{ch}\log\left(\frac{Q}{q}\right)^n=\sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{a-u}{b-u}}, \quad (28)$$

$$\text{sh}\, n\Omega=\text{sh}\log\left(\frac{Q}{q}\right)^n=\sqrt{\frac{a-b}{a-a'}}\sqrt{\frac{u-a'}{b-u}}. \quad (29)$$

At x where $\phi=\infty$, $u=0$, and $q=q_0$,

$$\left(\frac{Q}{q_0}\right)^n=\sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{a}{b}}+\sqrt{\frac{a-b}{a-a'}}\sqrt{\frac{-a'}{q}}. \quad (30)$$

In crossing to the line of flow x'A'P'J', ψ changes from 0 to m, so that with $q=Q$ across JJ', while across xx' the velocity is q_0, so that

$$m=q_0.xx'=Q.JJ' \quad (31)$$

$$\frac{JJ'}{xx'}=\frac{q_0}{Q}=\left[\sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{a}{b}}-\sqrt{\frac{a-b}{a-a'}}\sqrt{\frac{-a'}{b}}\right]^{1/n}, \quad (32)$$

giving the contraction of the jet compared with the initial breadth of the stream.

Along the line of flow x'A'P'J', $\psi=m$, $u=a'e^{-\pi\phi/m}$, and from x' to A', $\cos n\theta=1$, $\sin n\theta=0$,

$$\text{ch}\, n\Omega=\text{ch}\log\left(\frac{Q}{q}\right)^n=\sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{a-u}{b-u}}, \quad (33)$$

$$\text{sh}\, n\Omega=\text{sh}\log\left(\frac{Q}{q}\right)^n=\sqrt{\frac{a-b}{a-a'}}\sqrt{\frac{u-a'}{b-u}}, \quad (34)$$

$$0>u>a'. \quad (35)$$

Along the jet surface A'J', $q=Q$,

$$\text{ch}\, n\Omega=\cos n\theta=\sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{a-u}{b-u}}, \quad (36)$$

$$\text{sh}\, n\Omega=i\sin n\theta=i\sqrt{\frac{a-b}{a-a'}}\sqrt{\frac{a'-u}{b-u}}, \quad (37)$$

$$a'>u=a'e^{\pi/sc}>-\infty, \quad (38)$$

giving the intrinsic equation.

41. The first problem of this kind, worked out by H. v. Helmholtz, of the efflux of a jet between two edges A and A_1 in an infinite wall, is obtained by the symmetrical duplication of the above, with $n=1$, $b=0$, $a'=-\infty$, as in fig. 5,

$$\text{ch}\,\Omega=\sqrt{\frac{u-a}{u}},\ \text{sh}\,\Omega=\sqrt{\frac{-a}{u}}; \quad (1)$$

and along the jet APJ, $\infty>u=ae^{\pi s/c}>a$,

$$\text{sh}\,\Omega=i\sin\theta=i\sqrt{\frac{a}{u}}=ie^{-\frac{1}{2}\pi s/c}, \quad (2)$$

$$PM=\int_s^\infty\sin\theta\, ds=\int e^{-\frac{1}{2}\pi s/c}ds=\frac{c}{\frac{1}{2}\pi}e^{-\frac{1}{2}\pi s/c}=\frac{c}{\frac{1}{2}\pi}\sin\theta, \quad (3)$$

so that $PT = c/\frac{1}{2}\pi$, and the curve AP is the tractrix; and the coefficient of contraction, or

$$\frac{\text{breadth of the jet}}{\text{breadth of the orifice}} = \frac{\pi}{\pi+2}. \tag{4}$$

A change of Ω and θ into $n\Omega$ and $n\theta$ will give the solution for two walls converging symmetrically to the orifice AA_1 at an angle π/n. With $n=\frac{1}{2}$, the re-entrant walls are given of Borda's mouthpiece, and the coefficient of contraction becomes $\frac{1}{2}$. Generally, by making $a' = -\infty$, the line $x'A'$ may be taken as a straight stream line of infinite length, forming an axis of symmetry; and then by duplication the result can be obtained, with assigned n, a, and b, of the efflux from a symmetrical converging

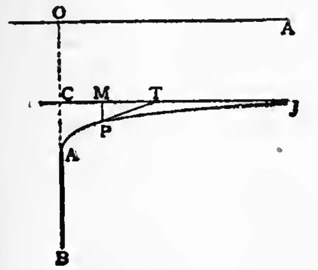

FIG. 5.

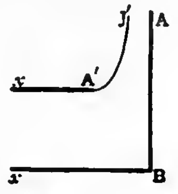

FIG. 6.

mouthpiece, or of the flow of water through the arches of a bridge, with wedge-shaped piers to divide the stream.

42. Other arrangements of the constants n, a, b, a' will give the results of special problems considered by J. M. Michell, *Phil. Trans.* 1890.

Thus with $a'=0$, a stream is split symmetrically by a wedge of angle π/n as in Bobyleff's problem; and, by making $a=\infty$, the wedge extends to infinity; then

$$\text{ch } n\Omega = \sqrt{\frac{b}{b-u}},\ \text{sh } n\Omega = \sqrt{\frac{n}{b-u}}. \tag{1}$$

Over the jet surface $\psi = m$, $q = Q$,

$$u = -e^{-\pi\phi/m} = -be^{\pi s/c},$$

$$\text{ch } \Omega = \cos n\theta = \sqrt{\frac{1}{e^{\pi s/c}+1}},\ \text{sh } \Omega = i \sin n\theta = i\sqrt{\frac{e^{\pi s/c}}{e^{\pi s/c}+1}}, \tag{2}$$

$$e^{\frac{1}{2}\pi s/c} = \tan n\theta,\ \frac{\frac{1}{2}\pi}{c}\frac{ds}{d\theta} = \frac{2n}{\sin 2n\theta}. \tag{3}$$

For a jet impinging normally on an infinite plane, as in fig. 6, $n=1$,

$$e^{\frac{1}{2}\pi s/c} = \tan\theta,\ \text{ch }(\tfrac{1}{2}\pi s/c)\sin 2\theta = 1, \tag{4}$$

$$\text{sh } \tfrac{1}{2}\pi x/c = \cot\theta,\ \text{sh } \tfrac{1}{2}\pi y/c = \tan\theta,$$

$$\text{sh } \tfrac{1}{2}\pi x/c \text{ sh } \tfrac{1}{2}\pi y/c = 1,\ e^{\frac{1}{2}\pi(x+y)/c} = e^{\frac{1}{2}\pi x/c} + e^{\frac{1}{2}\pi y/c} + 1. \tag{5}$$

With $n=\frac{1}{2}$, the jet is reversed in direction, and the profile is the catenary of equal strength.

In Bobyleff's problem of the wedge of finite breadth,

$$\text{ch } n\Omega = \sqrt{\frac{b}{a}}\sqrt{\frac{u-a}{u-b}},\ \text{sh } n\Omega = \sqrt{\frac{b-a}{a}}\sqrt{\frac{u}{u-b}}, \tag{6}$$

$$\cos n\alpha = \sqrt{\frac{b}{a}},\ \sin n\alpha = \sqrt{\frac{a-b}{a}}, \tag{7}$$

and along the free surface APJ, $q=Q$, $\psi=0$, $u = e^{-\pi\phi/m} = ae^{\pi s/c}$,

$$\cos n\theta = \cos n\alpha\sqrt{\frac{e^{\pi s/c}-1}{e^{\pi s/c}-\cos^2 n\alpha}},$$

$$e^{\pi s/c} = \frac{\cos^2 n\alpha \sin^2 n\theta}{\sin^2 n\theta - \sin^2 n\alpha}, \tag{8}$$

the intrinsic equation, the other free surface A'P'J' being given by

$$e^{\pi s/c} = \frac{\cos^2 n\alpha \sin^2 n\theta}{\sin^2 n\alpha - \sin^2 n\theta}. \tag{9}$$

Putting $n=1$ gives the case of a stream of finite breadth disturbed by a transverse plane, a particular case of Fig. 7.

When $a=b$, $\alpha=0$, and the stream is very broad compared with the wedge or lamina; so, putting $w = w'(a-b)/a$ in the penultimate case, and

$$u = ae^{-w} \approx a-(a-b)w', \tag{10}$$

$$\text{ch } n\Omega = \sqrt{\frac{w'+1}{w'}},\ \text{sh } n\Omega = \sqrt{\frac{1}{\sqrt{w'}}}, \tag{11}$$

in which we may write

$$w' = \phi + \psi i. \tag{12}$$

Along the stream line xABPJ, $\psi=0$; and along the jet surface APJ, $-1 > \phi > -\infty$; and putting $\phi = -\pi s/c - 1$, the intrinsic equation is

$$\pi s/c = \cot^2 n\theta, \tag{13}$$

which for $n=1$ is the evolute of a catenary.

43. When the barrier AA' is held oblique to the current, the stream line xB is curved to the branch point B on AA' (fig. 7), and so must be excluded from the boundary of u; the conformal representation is made now with

$$\frac{d\Omega}{du} = -\frac{\sqrt{(b-a.b-a')}}{(u-b)\sqrt{(u-a.u-a')}} \tag{1}$$

$$\frac{dw}{du} = -\frac{m}{\pi}\frac{1}{u-j} - \frac{m'}{\pi}\frac{1}{u-j},$$

$$= -\frac{m+m'}{\pi}\cdot\frac{u-b}{u-j.u-j'},$$

$$b = \frac{mj'+m'j}{m+m'}, \tag{2}$$

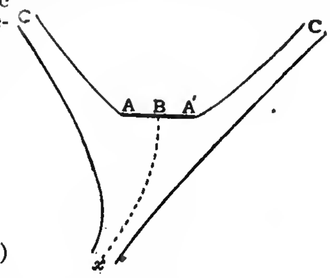

FIG. 7.

taking $u=\infty$ at the source where $\phi=\infty$, $u=b$ at the branch point B, $u=j, j'$ at the end of the two diverging streams where $\phi=-\infty$; while $\psi=0$ along the stream line which divides at B and passes through A, A'; and $\psi = m, -m'$ along the outside boundaries, so that m/Q, m'/Q is the final breadth of the jets, and $(m+m')/Q$ is the initial breadth, c, of the impinging stream. Then

$$\text{ch } \tfrac{1}{2}\Omega = \sqrt{\frac{b-a'}{a-a'}}\sqrt{\frac{u-a}{u-b}},\ \text{sh } \tfrac{1}{2}\Omega = \sqrt{\frac{b-a}{a-a'}}\sqrt{\frac{u-a'}{u-b}}, \tag{3}$$

$$\text{ch } \Omega = \frac{2b-a-a'}{a-a'} - \frac{N}{u-b},$$

$$\text{sh } \Omega = \sqrt{N}\frac{\sqrt{(2.a-u.u-a^1)}}{u-b},$$

$$N = 2\frac{a-b.b-a'}{a-a'}, \tag{4}$$

Along a jet surface, $q=Q$, and

$$\text{ch } \Omega = \cos\theta = \cos\alpha - \tfrac{1}{2}\sin^2\alpha(a-a')/(u-b), \tag{5}$$

if $\theta=\alpha$ at the source x of the jet xB, where $u=\infty$; and supposing $\theta=\beta, \beta'$ at the end of the streams where $u=j, j'$,

$$\frac{u-b}{a-a'} = \frac{\frac{1}{2}\sin^2\alpha}{\cos\alpha-\cos\theta},\ \frac{u-j}{a-a'} = \tfrac{1}{2}\sin^2\alpha\frac{\cos\theta-\cos\beta}{(\cos\alpha-\cos\beta)(\cos\alpha-\cos\theta)},$$

$$\frac{u-j'}{a-a'} = \tfrac{1}{2}\sin^2\alpha\frac{\cos\theta-\cos\beta'}{(\cos\alpha-\cos\beta')(\cos\alpha-\cos\theta)}; \tag{6}$$

and ψ being constant along a stream line

$$\frac{d\phi}{du} = \frac{dw}{du},\ Q\frac{ds}{d\theta} = \frac{d\phi}{d\theta} = \frac{dw}{du}\frac{du}{d\theta},$$

$$\frac{\pi Q}{m+m'}\frac{ds}{d\theta} = \frac{\pi}{c}\frac{ds}{d\theta} = \frac{(\cos\alpha-\cos\beta)(\cos\alpha-\cos\beta')\sin\theta}{(\cos\alpha-\cos\theta)(\cos\theta-\cos\beta)(\cos\theta-\cos\beta')},$$

$$= \frac{\sin\theta}{\cos\alpha-\cos\theta} + \frac{\cos\alpha-\cos\beta'}{\cos\beta-\cos\beta'}\cdot\frac{\sin\theta}{\cos\theta-\cos\beta}$$

$$\frac{\cos\alpha-\cos\beta}{\cos\beta-\cos\beta'}\cdot\frac{\sin\theta}{\cos\theta-\cos\beta'}, \tag{7}$$

giving the intrinsic equation of the surface of a jet, with proper attention to the sign.

From A to B, $a>u>b$, $\theta=0$,

$$\text{ch } \Omega = \text{ch} \log\frac{Q}{q} = \cos\alpha - \tfrac{1}{2}\sin^2\alpha\frac{a-a'}{a-b}$$

$$\text{sh } \Omega = \text{sh} \log\frac{Q}{q} = \frac{\sqrt{(a-u.u-a')}}{u-b}\sin\alpha$$

$$\frac{Q}{q} = \frac{(u-b)\cos\alpha - \frac{1}{2}(a-a')\sin^2\alpha + \sqrt{(a-u.u-a')}\sin\alpha}{u-b} \tag{8}$$

$$Q\frac{ds}{du} = Q\frac{ds}{d\phi}\frac{d\phi}{du} = -\frac{Q}{q}\frac{dw}{du}$$

$$= \frac{m+m'}{\pi}\cdot\frac{(u-b)\cos\alpha - \frac{1}{2}(a-a')\sin^2\alpha + \sqrt{(a-u.u-a')}\sin\alpha}{j-u.u-j'} \tag{9}$$

$$\pi\frac{AB}{c} = \int_b^a \frac{(2b-a-a')(u-b)-2(a-b)(b-a')+2\sqrt{(a-b.b-a'.a-u.u-a')}}{a-a'.j-u.u-j'}du, \tag{10}$$

with a similar expression for BA'.

The motion of a jet impinging on an infinite barrier is obtained by putting $j=a$, $j'=a'$; duplicated on the other side of the barrier, the motion reversed will represent the direct collision of two jets of unequal breadth and equal velocity. When the barrier is small compared with the jet, $\alpha=\beta=\beta'$, and G. Kirchhoff's solution is obtained of a barrier placed obliquely in an infinite stream.

Two corners B_1 and B_2 in the wall xA, with $a'=-\infty$, and $n=1$, will give the solution, by duplication, of a jet issuing by a reentrant mouthpiece placed symmetrically in the end wall of the channel; or else of the channel blocked partially by a diaphragm across the middle, with edges turned back symmetrically, problems discussed by J. H. Michell, A. E. H. Love and M. Réthy.

When the polygon is closed by the walls joining, instead of reaching back to infinity at xx', the liquid motion must be due to a source, and this modification has been worked out by B. Hopkinson in the *Proc. Lond. Math. Soc.*, 1898.

Michell has discussed also the hollow vortex stationary inside a polygon (*Phil. Trans.*, 1890); the solution is given by

$$\operatorname{ch} n\Omega = \operatorname{sn} w,\ \operatorname{sh} n\Omega = i \operatorname{cn} w \qquad (11)$$

so that, round the boundary of the polygon, $\psi = K'$, $\sin n\theta = 0$; and on the surface of the vortex $\psi = 0$, $q = Q$, and

$$\cos n\theta = \operatorname{sn}\phi,\ n\theta = \tfrac{1}{2}\pi - \operatorname{am} s/c, \qquad (12)$$

the intrinsic equation of the curve.

This is a closed Sumner line for $n = 1$, when the boundary consists of two parallel walls; and $n = \frac{1}{2}$ gives an Elastica.

44. *The Motion of a Solid through a Liquid.*—An important problem in the motion of a liquid is the determination of the state of velocity set up by the passage of a solid through it; and thence of the pressure and reaction of the liquid on the surface of the solid, by which its motion is influenced when it is free.

Beginning with a single body in liquid extending to infinity, and denoting by U, V, W, P, Q, R the components of linear and angular velocity with respect to axes fixed in the body, the velocity function takes the form

$$\phi = U\phi_1 + V\phi_2 + W\phi_3 + P\chi_1 + Q\chi_2 + R\chi_3, \qquad (1)$$

where the ϕ's and χ's are functions of x, y, z depending on the shape of the body; interpreted dynamically, $C - \rho\phi$ represents the impulsive pressure required to stop the motion, or $C + \rho\phi$ to start it again from rest.

The terms of ϕ may be determined one at a time, and this problem is purely kinematical; thus to determine ϕ_1, the component U alone is taken to exist, and then l, m, n, denoting the direction cosines of the normal of the surface drawn into the exterior liquid, the function ϕ_1 must be determined to satisfy the conditions

(i.) $\nabla^2\phi_1 = 0$, throughout the liquid;

(ii.) $\dfrac{d\phi_1}{d\nu} = -l$, the gradient of ϕ down the normal at the surface of the moving solid;

(iii.) $\dfrac{d\phi_1}{d\nu} = 0$, over a fixed boundary, or at infinity;

similarly for ϕ_2 and ϕ_3.

To determine χ_1 the angular velocity P alone is introduced, and the conditions to be satisfied are

(i.) $\nabla^2\chi_1 = 0$, throughout the liquid;

(ii.) $\dfrac{d\chi_1}{d\nu} = mz - ny$, at the surface of the moving body, but zero over a fixed surface, and at infinity; the same for χ_2 and χ_3.

For a cavity filled with liquid in the interior of the body, since the liquid inside moves bodily for a motion of translation only,

$$\phi_1 = -x,\ \phi_2 = -y,\ \phi_3 = -z; \qquad (2)$$

but a rotation will stir up the liquid in the cavity, so that the χ's depend on the shape of the surface.

The ellipsoid was the shape first worked out, by George Green, in his *Research on the Vibration of a Pendulum in a Fluid Medium* (1833); the extension to any other surface will form an important step in this subject.

A system of confocal ellipsoids is taken

$$\frac{x^2}{a^2+\lambda} + \frac{y^2}{b^2+\lambda} + \frac{z^2}{c^2+\lambda} = 1, \qquad (3)$$

and a velocity function of the form

$$\phi = x\psi, \qquad (4)$$

where ψ is a function of λ only, so that ψ is constant over an ellipsoid; and we seek to determine the motion set up, and the form of ψ which will satisfy the equation of continuity.

Over the ellipsoid, p denoting the length of the perpendicular from the centre on a tangent plane,

$$l = \frac{px}{a^2+\lambda},\quad m = \frac{py}{b^2+\lambda},\quad n = \frac{pz}{c^2+\lambda} \qquad (5)$$

$$1 = \frac{p^2x^2}{(a^2+\lambda)^2} + \frac{p^2y^2}{(b^2+\lambda)^2} + \frac{p^2z^2}{(c^2+\lambda)^2}, \qquad (6)$$

$$p^2 = (a^2+\lambda)l^2 + (b^2+\lambda)m^2 + (c^2+\lambda)n^2, \qquad (7)$$
$$= a^2l^2 + b^2m^2 + c^2n^2 + \lambda,$$

$$2p\frac{dp}{ds} = \frac{d\lambda}{ds}; \qquad (8)$$

Thence

$$\frac{d\phi}{ds} = \frac{dx}{ds}\psi + x\frac{d\psi}{ds}$$
$$= \frac{dx}{ds}\psi + 2(a^2+\lambda)\frac{d\psi}{d\lambda}\frac{l}{p}\frac{dp}{ds}, \qquad (9)$$

so that the velocity of the liquid may be resolved into a component $-\psi$ parallel to Ox, and $-2(a^2+\lambda)ld\psi/d\lambda$ along the normal of the ellipsoid; and the liquid flows over an ellipsoid along a line of slope with respect to Ox, treated as the vertical.

Along the normal itself

$$\frac{d\phi}{ds} = \left\{\psi + 2(a^2+\lambda)\frac{d\psi}{d\lambda}\right\} l, \qquad (10)$$

so that over the surface of an ellipsoid where λ and ψ are constant, the normal velocity is the same as that of the ellipsoid itself, moving as a solid with velocity parallel to Ox

$$U = -\psi - 2(a^2+\lambda)\frac{d\psi}{d\lambda}, \qquad (11)$$

and so the boundary condition is satisfied; moreover, any ellipsoidal surface λ may be supposed moving as if rigid with the velocity in (11), without disturbing the liquid motion for the moment.

The continuity is secured if the liquid between two ellipsoids λ and λ_1, moving with the velocity U and U_1 of equation (11), is squeezed out or sucked in across the plane $x = 0$ at a rate equal to the integral flow of the velocity ψ across the annular area $\alpha_1 - \alpha$ of the two ellipsoids made by $x = 0$; or if

$$\alpha U - \alpha_1 U_1 = \int_\lambda^{\lambda_1} \psi \frac{d\alpha}{d\lambda} d\lambda, \qquad (12)$$

$$\alpha = \pi\sqrt{(b^2+\lambda \,.\, c^2+\lambda)}. \qquad (13)$$

Expressed as a differential relation, with the value of U from (11),

$$\frac{d}{d\lambda}\left[\alpha\psi + 2(a^2+\lambda)\alpha\frac{d\psi}{d\lambda}\right] - \psi\frac{d\alpha}{d\lambda} = 0, \qquad (14)$$

$$3\alpha\frac{d\psi}{d\lambda} + 2(a^2+\lambda)\frac{d}{d\lambda}\left(\alpha\frac{d\psi}{d\lambda}\right) = 0, \qquad (15)$$

and integrating

$$(a^2+\lambda)^{3/2}\alpha\frac{d\psi}{d\lambda} = \text{a constant}, \qquad (16)$$

so that we may put

$$\psi = \int \frac{M\,d\lambda}{(a^2+\lambda)P}, \qquad (17)$$

$$P^2 = 4(a^2+\lambda)(b^2+\lambda)(c^2+\lambda), \qquad (18)$$

where M denotes a constant; so that ψ is an elliptic integral of the second kind.

The quiescent ellipsoidal surface, over which the motion is entirely tangential, is the one for which

$$2(a^2+\lambda)\frac{d\psi}{d\lambda} + \psi = 0, \qquad (19)$$

and this is the infinite boundary ellipsoid if we make the upper limit $\lambda_1 = \infty$.

The velocity of the ellipsoid defined by $\lambda = 0$ is then

$$U = -2a^2\frac{d\psi_0}{d\lambda} - \psi_0$$
$$= \frac{M}{abc} - \int_0^\infty \frac{M\,d\lambda}{(a^2+\lambda)P}$$
$$= \frac{M}{abc}(1 - A_0), \qquad (20)$$

with the notation

$$A \text{ or } A_\lambda = \int_\lambda^\infty \frac{abc\,d\lambda}{(a^2+\lambda)P}$$
$$= -2abc\frac{d}{da^2}\int_\lambda^\infty \frac{d\lambda}{P}, \qquad (21)$$

so that in (4)

$$\phi = \frac{M}{abc}xA = \frac{UxA}{1-A_0},\quad \phi_1 = \frac{xA_\lambda}{1-A_0}, \qquad (22)$$

in (1) for an ellipsoid.

The impulse required to set up the motion in liquid of density ρ is the resultant of an impulsive pressure $\rho\phi$ over the surface S of the ellipsoid, and is therefore

$$\iint \rho\phi l\,dS = \rho\psi_0 \iint xl\,dS$$
$$= \rho\psi_0 \text{ (volume of the ellipsoid)} = \psi_0 W', \qquad (23)$$

where W′ denotes the weight of liquid displaced.

Denoting the effective inertia of the liquid parallel to Ox by $\alpha W'$, the momentum

$$\alpha W' U = \psi_0 W' \qquad (24)$$

$$\alpha = \frac{\psi_0}{U} = \frac{A_0}{1 - A_0}; \qquad (25)$$

in this way the air drag was calculated by Green for an ellipsoidal pendulum.

Similarly, the inertia parallel to Oy and Oz is

$$\beta W' = \frac{B_0}{1-B_0}W',\quad \gamma W' = \frac{C_0}{1-C_0}W', \qquad (26)$$

$$B_\lambda,\ C_\lambda = \int_\lambda^\infty \frac{abc\,d\lambda}{(b^2+\lambda,\ c^2+\lambda)P}; \qquad (27)$$

and

$$A + B + C = abc/\tfrac{1}{2}P,\quad A_0 + B_0 + C_0 = 1. \qquad (28)$$

For a sphere

$$a = b = c,\ A_0 = B_0 = C_0 = \tfrac{1}{3},\ \alpha = \beta = \gamma = \tfrac{1}{2}, \qquad (29)$$

so that the effective inertia of a sphere is increased by half the weight of liquid displaced; and in frictionless air or liquid the sphere, of weight W, will describe a parabola with vertical acceleration

$$\frac{W-W'}{W+\frac{1}{2}W'}g. \qquad (30)$$

Thus a spherical air bubble, in which W/W′ is insensible, will begin to rise in water with acceleration $2g$.

45. When the liquid is bounded externally by the fixed ellipsoid $\lambda=\lambda_1$, a slight extension will give the velocity function ϕ of the liquid in the interspace as the ellipsoid $\lambda=0$ is passing with velocity U through the confocal position; ϕ must now take the form $x(\psi+N)$, and will satisfy the conditions in the shape

$$\phi = Ux\frac{A+B_1+C_1}{B_0+C_0-B_1-C_1} = Ux\frac{\dfrac{abc}{a_1b_1c_1}+\displaystyle\int_\lambda^{\lambda_1}\frac{abcd\lambda}{(a^2+\lambda)P}}{1-\dfrac{abc}{a_1b_1c_1}-\displaystyle\int_0^{\lambda_1}\frac{abcd\lambda}{(a^2+\lambda)P}}, \qquad (1)$$

and any confocal ellipsoid defined by λ, internal or external to $\lambda=\lambda_1$, may be supposed to swim with the liquid for an instant, without distortion or rotation, with velocity along Ox

$$U\frac{B_\lambda+C_\lambda-B_1-C_1}{B_0+C_0-B_1-C_1}.$$

Since $-Ux$ is the velocity function for the liquid W′ filling the ellipsoid $\lambda=0$, and moving bodily with it, the effective inertia of the liquid in the interspace is

$$\frac{A_0+B_1+C_1}{B_0+C_0-B_1-C_1}W'. \qquad (2)$$

If the ellipsoid is of revolution, with $b=c$,

$$\phi=\tfrac{1}{2}Ux\frac{A+2B_1}{B_0-B_1}, \qquad (3)$$

and the Stokes' current function ψ can be written down

$$\psi=-\tfrac{1}{2}Uy^2\frac{B-B_1}{B_0-B_1}; \qquad (4)$$

reducing, when the liquid extends to infinity and $B_1=0$, to

$$\phi=\tfrac{1}{2}Ux\frac{A}{B_0},\quad \psi=-\tfrac{1}{2}Uy^2\frac{B}{B_0}; \qquad (5)$$

so that in the relative motion past the body, as when fixed in the current U parallel to xO,

$$\phi'=\tfrac{1}{2}Ux\left(1+\frac{A}{B_0}\right),\quad \psi'=\tfrac{1}{2}Uy^2\left(1-\frac{B}{B_0}\right). \qquad (6)$$

Changing the origin from the centre to the focus of a prolate spheroid, then putting $b^2=pa$, $\lambda=\lambda'a$, and proceeding to the limit where $a=\infty$, we find for a paraboloid of revolution

$$B=\tfrac{1}{2}\frac{p}{p+\lambda'},\quad \frac{B}{B_0}=\frac{p}{p+\lambda'}, \qquad (7)$$

$$\frac{y^2}{p+\lambda'}=p+\lambda'-2x, \qquad (8)$$

with $\lambda'=0$ over the surface of the paraboloid; and then

$$\psi'=\tfrac{1}{2}U[y^2-p\sqrt{(x^2+y^2)}+px]; \qquad (9)$$

$$\psi=-\tfrac{1}{2}Up[\sqrt{(x^2+y^2)}-x]; \qquad (10)$$

$$\phi=-\tfrac{1}{2}Up\log[\sqrt{(x^2+y^2)}+x]. \qquad (11)$$

The relative path of a liquid particle is along a stream line

$$\psi'=\tfrac{1}{2}Uc^2, \text{ a constant}, \qquad (12)$$

$$x=\frac{p^2y^2-(y^2-c^2)^2}{2p(y^2-c^2)},\quad \sqrt{(x^2+y^2)}=\frac{p^2y^2+(y^2-c^2)^2}{2p(y^2-c^2)} \qquad (13)$$

a C_4; while the absolute path of a particle in space will be given by

$$\frac{dy}{dx}=-\frac{r-x}{y}=-\frac{y^2-c^2}{2py}, \qquad (14)$$

$$y^2-c^2=a^2e^{-x/p}. \qquad (15)$$

46. Between two concentric spheres, with

$$a^2+\lambda=r^2,\quad a^2+\lambda_1=a_1^2, \qquad (1)$$

$$A=B=C=a^3/3r^3,$$

$$\phi=\tfrac{1}{2}Ux\frac{\dfrac{a^3}{r^3}+2\dfrac{a^3}{a_1^3}}{1-a^3/a_1^3},\quad \psi=\tfrac{1}{2}Uy^2\frac{\dfrac{a^3}{r^3}-\dfrac{a^3}{a_1^3}}{1-a^3/a_1^3}; \qquad (2)$$

and the effective inertia of the liquid in the interspace is

$$\frac{A_0+2A_1}{2A_0-2A_1}W'=\tfrac{1}{2}\frac{a_1^3+2a^3}{a_1^3-a^3}W'. \qquad (3)$$

When the spheres are not concentric, an expression for the effective inertia can be found by the method of images (W. M. Hicks, *Phil. Trans.*, 1880).

The image of a source of strength μ at S outside a sphere of radius a is a source of strength $\mu a/f$ at H, where OS$=f$, OH$=a^2/f$, and a line sink reaching from the image H to the centre O of line strength $-\mu/a$; this combination will be found to produce no flow across the surface of the sphere.

Taking Ox along OS, the Stokes' function at P for the source S is $\mu\cos$ PSx, and of the source H and line sink OH is $\mu(a/f)\cos$ PHx and $-(\mu/a)$(PO − PH); so that

$$\psi=\mu\left(\cos PSx+\frac{a}{f}\cos PHx-\frac{PO-PH}{a}\right), \qquad (4)$$

and $\psi=-\mu$, a constant, over the surface of the sphere, so that there is no flow across.

When the source S is inside the sphere and H outside, the line sink must extend from H to infinity in the image system; to realize physically the condition of zero flow across the sphere, an equal sink must be introduced at some other internal point S′.

When S and S′ lie on the same radius, taken along Ox, the Stokes' function can be written down; and when S and S′ coalesce a doublet is produced, with a doublet image at H.

For a doublet at S, of moment m, the Stokes' function is

$$m\frac{d}{df}\cos PSx=-m\frac{y^2}{PS^3}; \qquad (5)$$

and for its image at H the Stokes' function is

$$m\frac{d}{df}\cos PHx=m\frac{a^3}{f^3}\frac{y^2}{PH^3}; \qquad (6)$$

so that for the combination

$$\psi=my^2\left(\frac{a^3}{f^3}\frac{1}{PH^3}-\frac{1}{PS^3}\right)=m\frac{y^2}{f^3}\left(\frac{a^3}{PH^3}-\frac{f^3}{PS^3}\right), \qquad (7)$$

and this vanishes over the surface of the sphere.

There is no Stokes' function when the axis of the doublet at S does not pass through O; the image system will consist of an inclined doublet at H, making an equal angle with OS as the doublet S, and of a parallel negative line doublet, extending from H to O, of moment varying as the distance from O.

A distribution of sources and doublets over a moving surface will enable an expression to be obtained for the velocity function of a body moving in the presence of a fixed sphere, or inside it.

The method of electrical images will enable the stream function ψ' to be inferred from a distribution of doublets, finite in number when the surface is composed of two spheres intersecting at an angle π/m, where m is an integer (R. A. Herman, *Quart. Jour. of Math.* xxii.).

Thus for $m=2$, the spheres are orthogonal, and it can be verified that

$$\psi'=\tfrac{1}{2}Uy^2\left(1-\frac{a_1^3}{r_1^3}-\frac{a_2^3}{r_2^3}+\frac{a^3}{r^3}\right), \qquad (8)$$

where a_1, a_2, $a=a_1a_2/\sqrt{(a_1^2+a_2^2)}$ is the radius of the spheres and their circle of intersection, and r_1, r_2, r the distances of a point from their centres.

The corresponding expression for two orthogonal cylinders will be

$$\psi'=Uy\left(1-\frac{a_1^2}{r_1^2}-\frac{a_2^2}{r_2^2}+\frac{a^2}{r^2}\right). \qquad (9)$$

With $a_2=\infty$, these reduce to

$$\psi'=\tfrac{1}{2}Uy^2\left(1-\frac{a^5}{r^5}\right)\frac{x}{a},\ \text{or}\ Uy\left(1-\frac{a^4}{r^4}\right)\frac{x}{a}, \qquad (10)$$

for a sphere or cylinder, and a diametral plane.

Two equal spheres, intersecting at 120°, will require

$$\psi'=\tfrac{1}{2}Uy^2\left[\frac{x}{a}-\frac{a^3}{2r_1^3}+\frac{a^4(a-2x)}{2r_1^5}+\frac{a^3}{2r_2^3}-\frac{a^4(a+2x)}{2r_2^5}\right], \qquad (11)$$

with a similar expression for cylinders; so that the plane $x=0$ may be introduced as a boundary, cutting the surface at 60°. The motion of these cylinders across the line of centres is the equivalent of a line doublet along each axis.

47. The extension of Green's solution to a rotation of the ellipsoid was made by A. Clebsch, by taking a velocity function

$$\phi=xy\chi \qquad (1)$$

for a rotation R about Oz; and a similar procedure shows that an ellipsoidal surface λ may be in rotation about Oz without disturbing the motion if

$$R=-\frac{\left(\dfrac{1}{a^2+\lambda}+\dfrac{1}{b^2+\lambda}\right)\chi\mp2\dfrac{d\chi}{d\lambda}}{1/(b^2+\lambda)-1/(a^2+\lambda)}, \qquad (2)$$

and that the continuity of the liquid is secured if

$$(a^2+\lambda)^{3/2}(b^2+\lambda)^{3/2}(c^2+\lambda)^{\frac{1}{2}}\frac{d\chi}{d\lambda}=\text{constant}, \qquad (3)$$

$$\chi=\int_\lambda^\infty\frac{Nd\lambda}{(a^2+\lambda)(b^2+\lambda)P}=\frac{N}{abc}\cdot\frac{B_\lambda-A_\lambda}{a^2-b^2}; \qquad (4)$$

and at the surface $\lambda=0$,

$$R=-\frac{\left(\dfrac{1}{a^2}+\dfrac{1}{b^2}\right)\dfrac{N}{abc}\dfrac{B_0-A_0}{a^2-b^2}-\dfrac{N}{abc}\dfrac{1}{a^2b^2}}{1/b^2-1/a^2}, \qquad (5)$$

$$\frac{N}{abc}=R\frac{1/b^2-1/a^2}{\dfrac{1}{a^2b^2}-\left(\dfrac{1}{a^2}+\dfrac{1}{b^2}\right)\dfrac{B_0-A_0}{a^2-b^2}}, \qquad (6)$$

$$=R\frac{(a^2-b^2)^2/(a^2+b^2)}{(a^2-b^2)/(a^2+b^2)-(B_0-A_0)}.$$

The velocity function of the liquid inside the ellipsoid $\lambda=0$ due to the same angular velocity will be

$$\phi_1=Rxy(a^2-b^2)/(a^2+b^2), \tag{7}$$

and on the surface outside

$$\phi_0=xy\chi_0=xy\frac{N}{abc}\frac{B_0-A_0}{a^2-b^2}, \tag{8}$$

so that the ratio of the exterior and interior value of ϕ at the surface is

$$\frac{\phi_0}{\phi_1}=\frac{B_0-A_0}{(a^2-b^2)/(a^2+b^2)-(B_0-A_0)}, \tag{9}$$

and this is the ratio of the effective angular inertia of the liquid, outside and inside the ellipsoid $\lambda=0$.

The extension to the case where the liquid is bounded externally by a fixed ellipsoid $\lambda=\lambda_1$ is made in a similar manner, by putting

$$\phi=xy(\chi+M), \tag{10}$$

and the ratio of the effective angular inertia in (9) is changed to

$$\frac{(B_0-A_0)-(B_1-A_1)+\dfrac{a_1^2-b_1^2}{a_1^2+b_1^2}\dfrac{abc}{a_1b_1c_1}}{\dfrac{a^2-b^2}{a^2+b^2}-\dfrac{a_1^2-b_1^2}{a_1^2+b_1^2}\dfrac{abc}{a_1b_1c_1}-(B_0-A_0)+(B_1-A_1)}. \tag{11}$$

Make $c=\infty$ for confocal elliptic cylinders; and then

$$A_\lambda=\int_\lambda^\infty\frac{ab}{(a^2+\lambda)\sqrt{(4.a^2+\lambda.b^2+\lambda)}}=\frac{ab}{a^2-b^2}\left(1-\sqrt{\frac{b^2+\lambda}{a^2+\lambda}}\right), \tag{12}$$

$$B_\lambda=\frac{ab}{a^2-b^2}\left(\sqrt{\frac{a^2+\lambda}{b^2+\lambda}}-1\right),\quad C_\lambda=0;$$

and then as above in § 31, with

$$a=c\ \mathrm{ch}\ \alpha,\ b=c\ \mathrm{sh}\ \alpha,\ a_1=\sqrt{(a^2+\lambda)}=c\ \mathrm{ch}\ \alpha_1,\ b_1=c\ \mathrm{sh}\ \alpha_1 \tag{13}$$

the ratio in (11) agrees with § 31 (6).

As before in § 31, the rotation may be resolved into a shear-pair, in planes perpendicular to Ox and Oy.

A torsion of the ellipsoidal surface will give rise to a velocity function of the form $\phi=xyz\Omega$, where Ω can be expressed by the elliptic integrals A_λ, B_λ, C_λ, in a similar manner, since

$$\Omega=L\int_\lambda^\infty d\lambda/P^3.$$

48. The determination of the ϕ's and χ's is a kinematical problem, solved as yet only for a few cases, such as those discussed above.

But supposing them determined for the motion of a body through a liquid, the kinetic energy T of the system, liquid and body, is expressible as a quadratic function of the components U, V, W, P, Q, R. The partial differential coefficient of T with respect to a component of velocity, linear or angular, will be the component of momentum, linear or angular, which corresponds.

Conversely, if the kinetic energy T is expressed as a quadratic function of $x_1, x_2, x_3, y_1, y_2, y_3$, the components of momentum, the partial differential coefficient with respect to a momentum component will give the component of velocity to correspond.

These theorems, which hold for the motion of a single rigid body, are true generally for a flexible system, such as considered here for a liquid, with one or more rigid bodies swimming in it; and they express the statement that the work done by an impulse is the product of the impulse and the arithmetic mean of the initial and final velocity; so that the kinetic energy is the work done by the impulse in starting the motion from rest.

Thus if T is expressed as a quadratic function of U, V, W, P, Q, R, the components of momentum corresponding are

$$x_1=\frac{dT}{dU},\ x_2=\frac{dT}{dV},\ x_3=\frac{dT}{dW}, \tag{1}$$

$$y_1=\frac{dT}{dP},\ y_2=\frac{dT}{dQ},\ y_3=\frac{dT}{dR};$$

but when it is expressed as a quadratic function of $x_1, x_2, x_3, y_1, y_2, y_3$,

$$U=\frac{dT}{dx_1},\ V=\frac{dT}{dx_2},\ W=\frac{dT}{dx_3}, \tag{2}$$

$$P=\frac{dT}{dy_1},\ Q=\frac{dT}{dy_2},\ R=\frac{dT}{dy_3}.$$

The second system of expression was chosen by Clebsch and adopted by Halphen in his *Fonctions elliptiques*; and thence the dynamical equations follow

$$X=\frac{dx_1}{dt}-x_2\frac{dT}{dy_3}+x_3\frac{dT}{dy_2},\ Y=\ldots,\ Z=\ldots, \tag{3}$$

$$L=\frac{dy_1}{dt}-y_2\frac{dT}{dy_3}+y_3\frac{dT}{dy_2}-x_2\frac{dT}{dx_3}+x_3\frac{dT}{dx_2},\ M=\ldots,\ N=\ldots, \tag{4}$$

where X, Y, Z, L, M, N denote components of external applied force on the body.

These equations are proved by taking a line fixed in space, whose direction cosines are l, m, n, then

$$\frac{dl}{dt}=mR-nQ,\ \frac{dm}{dt}=nP-lR,\ \frac{dn}{dt}=lQ-mP. \tag{5}$$

If P denotes the resultant linear impulse or momentum in this direction

$$P=lx_1+mx_2+nx_3, \tag{6}$$

$$\begin{aligned}\frac{dP}{dt}&=\frac{dl}{dt}x_1+\frac{dm}{dt}x_2+\frac{dn}{dt}x_3\\&\quad+l\frac{dx_1}{dt}+m\frac{dx_2}{dt}+n\frac{dx_3}{dt},\\&=l\left(\frac{dx_1}{dt}-x_2R+x_3Q\right)\\&\quad+m\left(\frac{dx_2}{dt}-x_3P+x_1R\right)\\&\quad+n\left(\frac{dx_3}{dt}-x_1Q+x_2P\right)\\&=lX+mY+nZ,\end{aligned} \tag{7}$$

for all values of l, m, n.

Next, taking a fixed origin Ω and axes parallel to Ox, Oy, Oz through O, and denoting by x, y, z the coordinates of O, and by G the component angular momentum about Ω in the direction (l, m, n)

$$\begin{aligned}G&=l(y_1-x_2z+x_3y)\\&\quad+m(y_2-x_3x+x_1z)\\&\quad+n(y_3-x_1y+x_2x).\end{aligned} \tag{8}$$

Differentiating with respect to t, and afterwards moving the fixed origin up to the moving origin O, so that

$$x=y=z=0,\ \text{but}\ \frac{dx}{dt}=U,\ \frac{dy}{dt}=V,\ \frac{dz}{dt}=W,$$

$$\begin{aligned}\frac{dG}{dt}&=l\left(\frac{dy_1}{dt}-y_2R+y_3Q-x_2W+x_3V\right)\\&\quad+m\left(\frac{dy_2}{dt}-y_3P+y_1R-x_3U+x_1W\right)\\&\quad+n\left(\frac{dy_3}{dt}-y_1Q+y_2P-x_1V+x_2U\right)\\&=lL+mM+nN,\end{aligned} \tag{9}$$

for all values of l, m, n.

When no external force acts, the case which we shall consider, there are three integrals of the equations of motion

(i.) $T=$constant,
(ii.) $x_1^2+x_2^2+x_3^2=F^2$, a constant,
(iii.) $x_1y_1+x_2y_2+x_3y_3=n=GF$, a constant;

and the dynamical equations in (3) express the fact that x_1, x_2, x_3 are the components of a constant vector having a fixed direction; while (4) shows that the vector resultant of y_1, y_2, y_3 moves as if subject to a couple of components

$$x_2W-x_3V,\ x_3U-x_1W,\ x_1V-x_2U, \tag{10}$$

and the resultant couple is therefore perpendicular to F, the resultant of x_1, x_2, x_3, so that the component along OF is constant, as expressed by (iii).

If a fourth integral is obtainable, the solution is reducible to a quadrature, but this is not possible except in a limited series of cases, investigated by H. Weber, F. Kötter, R. Liouville, Caspary, Jukovsky, Liapounoff, Kolosoff and others, chiefly Russian mathematicians; and the general solution requires the double-theta hyperelliptic function.

49. In the motion which can be solved by the elliptic function, the most general expression of the kinetic energy was shown by A. Clebsch to take the form

$$\begin{aligned}T&=\tfrac12p(x_1^2+x_2^2)+\tfrac12p'x_3^2\\&\quad+q(x_1y_1+x_2y_2)+q'x_3y_3\\&\quad+\tfrac12r(y_1^2+y_2^2)+\tfrac12r'y_3^2\end{aligned} \tag{1}$$

so that a fourth integral is given by

$$dy_3/dt=0,\ y_3=\text{constant}; \tag{2}$$

$$\frac{dx_3}{dt}=x_1(qx_2+ry_2)-x_2(qx_1+ry_1)=r(x_1y_2-x_2y_1), \tag{3}$$

$$\begin{aligned}\frac{1}{r^2}\left(\frac{dx_3}{dt}\right)^2&=(x_1^2+x_2^2)(y_1^2+y_2^2)-(x_1y_1+x_2y_2)^2\\&=(x_1^2+x_2^2)(y_1^2+y_2^2)-(FG-x_3y_3)^2\\&=(x_1^2+x_2^2)(y_1^2+y_2^2+y_3^2-G^2)-(Gx_3-Fy_3)^2,\end{aligned} \tag{4}$$

in which

$$x_1^2+x_2^2=F^2-x_3^2,\ x_1y_1+x_2y_2=FG-x_3y_3, \tag{5}$$

$$\begin{aligned}r(y_1^2+y_2^2)&=2T-p(x_1^2+x_2^2)-p'x_3^2\\&\quad-2q(x_1y_1+x_2y_2)-2q'x_3y_3-r'y_3^2\\&=(p-p')x_3^2+2(q-q')x_3y_3+m_1,\end{aligned} \tag{6}$$

$$m_1=2T-pF^2-2qFG-r_1y_3^2 \tag{7}$$

so that

$$\frac{1}{r^2}\left(\frac{dx_3}{dt}\right)^2=X_3, \tag{8}$$

where X_3 is a quartic function of x_3, and thus t is given by an elliptic integral of the first kind; and by inversion x_3 is in elliptic function of the time t. Now

$$(x_1-x_2i)(y_1+y_2i)=x_1y_1+x_2y_2+i(x_1y_2-x_2y_1)$$
$$=FG-x_3y_3+i\sqrt{X_3}, \qquad (9)$$

$$\frac{y_1+y_2i}{x_1+x_2i}=\frac{FG-x_3y_3+i\sqrt{X_3}}{x_1^2+x_2^2}, \qquad (10)$$

$$\frac{d}{dt}(x_1+x_2i)=-i[(q'-q)x_3+r'y_3]+irx_3(y_1+y_2i), \qquad (11)$$

$$\frac{d}{dti}\log(x_1+x_2i)=-(q'-q)x_3-r'y_3+rx_3\frac{FG-x_3y_3+i\sqrt{X_3}}{F^2-x_3^2}, \qquad (12)$$

$$\frac{d}{dti}\log\sqrt{\frac{x_1+x_2i}{x_1-x_2i}}=-(q'-q)x_3-(r'-r)y_3-Fr\frac{Fy_3-Gx_3}{F^2-x_3^2}, \qquad (13)$$

requiring the elliptic integral of the third kind; thence the expression of x_1+x_2i and y_1+y_2i.

Introducing Euler's angles θ, ϕ, ψ,

$$x_1=F\sin\theta\sin\phi,\ x_2=F\sin\theta\cos\phi,$$
$$x_1+x_2i=iF\sin\theta e^{-\phi i},\ x_3=F\cos\theta; \qquad (14)$$

$$\sin\theta\frac{d\psi}{dt}=P\sin\phi+Q\cos\phi, \qquad (15)$$

$$F\sin^2\theta\frac{d\psi}{dt}=\frac{dT}{dy_1}x_1+\frac{dT}{dy_2}x_2$$
$$=(qx_1+ry_1)x_1+(qx_2+ry_2)x_2$$
$$=q(x_1^2+x_2^2)+r(x_1y_1+x_2y_2)$$
$$=qF^2\sin^2\theta+r(FG-x_3y_3), \qquad (16)$$

$$\psi-qFt=\int\frac{FG-x_3y_3}{F^2-x_3^2}\frac{Frdx_3}{\sqrt{X_3}}, \qquad (17)$$

elliptic integrals of the third kind.

Employing G. Kirchhoff's expressions for X, Y, Z, the coordinates of the centre of the body,

$$FX=y_1\cos\overline{xY}+y_2\cos\overline{yY}+y_3\cos\overline{zY}, \qquad (18)$$
$$FY=-y_1\cos\overline{xX}+y_2\cos\overline{yX}+y_3\cos\overline{zX}, \qquad (19)$$
$$G=y_1\cos\overline{xZ}+y_2\cos\overline{yZ}+y_3\cos\overline{zZ}, \qquad (20)$$
$$F^2(X^2+Y^2)=y_1^2+y_2^2+y_3^2-G^2, \qquad (21)$$
$$F(X+Yi)=\frac{Fy_3-Gx_3+i\sqrt{X_3}}{\sqrt{(F^2-x_3^2)}}e^{\psi i}. \qquad (22)$$

Suppose x_3-F is a repeated factor of X_3, then $y_3=G$, and

$$X_3=(x_3-F)^2\left[\frac{p'-p}{r}(x_3+F)^2+2\frac{q'-q}{r}G(x_3+F)-G^2\right], \qquad (23)$$

and putting $x_3-F=y$,

$$\left(\frac{dy}{dt}\right)^2=r^2y^2\left[4\frac{p'-p}{r}F^2+4\frac{q'-q}{r}FG-G^2\right.$$
$$\left.+2\left(2\frac{p'-p}{r}F+\frac{q'-q}{r}G\right)y+\frac{p'-p}{r}y^2\right], \qquad (24)$$

so that the stability of this axial movement is secured if

$$A=4\frac{p'-p}{r}F^2+4\frac{q'-q}{r}FG-G^2 \qquad (25)$$

is negative, and then the axis makes $r\sqrt{(-A)}/\pi$ nutations per second. Otherwise, if A is positive

$$rt=\int\frac{dy}{y\sqrt{(A+2By+Cy^2)}}$$
$$=\frac{1}{\sqrt{A}}\frac{\mathrm{sh}^{-1}}{\mathrm{ch}^{-1}}\frac{\sqrt{A}\sqrt{(A+2By+Cy^2)}}{y\sqrt{(B^2\sim AC)}}=\frac{1}{\sqrt{A}}\frac{\mathrm{ch}^{-1}}{\mathrm{sh}^{-1}}\frac{A+By}{y\sqrt{(B^2\sim AC)}}, \qquad (26)$$

and the axis falls away ultimately from its original direction.

A number of cases are worked out in the *American Journal of Mathematics* (1907), in which the motion is made algebraical by the use of the pseudo-elliptic integral. To give a simple instance, changing to the stereographic projection by putting $\tan\frac{1}{2}\theta=x$,

$$(Nxe^{\psi i})^{3/2}=(x+1)\sqrt{X_1}+i(x-1)\sqrt{X_2}, \qquad (27)$$
$$\frac{X_1}{X_2}=\pm ax^4+2ax^3\pm3(a+b)x^2+2bx\pm b, \qquad (28)$$
$$N^3=-8(a+b), \qquad (29)$$

will give a possible state of motion of the axis of the body; and the motion of the centre may then be inferred from (22).

50. The theory preceding is of practical application in the investigation of the stability of the axial motion of a submarine boat, of the elongated gas bag of an airship, or of a spinning rifled projectile. In the steady motion under no force of such a body in a medium, the centre of gravity describes a helix, while the axis describes a cone round the direction of motion of the centre of gravity, and the couple causing precession is due to the displacement of the medium.

In the absence of a medium the inertia of the body to translation is the same in all directions, and is measured by the weight W, and under no force the C.G. proceeds in a straight line, and the axis of rotation through the C.G. preserves its original direction, if a principal axis of the body; otherwise the axis describes a cone, right circular if the body has uniaxial symmetry, and a Poinsot cone in the general case.

But the presence of the medium makes the effective inertia depend on the direction of motion with respect to the external shape of the body, and on W′ the weight of fluid medium displaced.

Consider, for example, a submarine boat under water; the inertia is different for axial and broadside motion, and may be represented by

$$c_1=W+W'\alpha,\ c_2=W+W'\beta, \qquad (1)$$

where α, β are numerical factors depending on the external shape; and if the C.G is moving with velocity V at an angle ϕ with the axis, so that the axial and broadside component of velocity is $u=V\cos\phi$, $v=V\sin\phi$, the total momentum F of the medium, represented by the vector OF at an angle θ with the axis, will have components, expressed in sec. lb,

$$F\cos\theta=c_1\frac{u}{g}=(W+W'\alpha)\frac{V}{g}\cos\phi,\ F\sin\theta=c_2\frac{v}{g}=(W+W'\beta)\frac{V}{g}\sin\phi. \quad (2)$$

Suppose the body is kept from turning as it advances; after t seconds the C.G. will have moved from O to O′, where OO′$=Vt$; and at O′ the momentum is the same in magnitude as before, but its vector is displaced from OF to O′F′.

For the body alone the resultant of the components of momentum

$$W\frac{V}{g}\cos\phi \text{ and } W\frac{V}{g}\sin\phi \text{ is } W\frac{V}{g}\text{sec. lb}, \qquad (3)$$

acting along OO′, and so is unaltered.

But the change of the resultant momentum F of the medium as well as of the body from the vector OF to O′F′ requires an impulse couple, tending to increase the angle FOO′, of magnitude, in sec. foot-pounds

$$F.OO'.\sin FOO'=FVt\sin(\theta-\phi), \qquad (4)$$

equivalent to an incessant couple

$$N=FV\sin(\theta-\phi)$$
$$=(F\sin\theta\cos\phi-F\cos\theta\sin\phi)V$$
$$=(c_2-c_1)(V^2/g)\sin\phi\cos\phi$$
$$=W'(\beta-\alpha)uv/g. \qquad (5)$$

This N is the couple in foot-pounds changing the momentum of the medium, the momentum of the body alone remaining the same; the medium reacts on the body with the same couple N in the opposite direction, tending when c_2-c_1 is positive to set the body broadside to the advance.

An oblate flattened body, like a disk or plate, has c_2-c_1 negative, so that the medium steers the body axially; this may be verified by a plate dropped in water, and a leaf or disk or rocket-stick or piece of paper falling in air. A card will show the influence of the couple N if projected with a spin in its plane, when it will be found to change its aspect in the air.

An elongated body like a ship has c_2-c_1 positive, and the couple N tends to disturb the axial movement and makes it unstable, so that a steamer requires to be steered by constant attention at the helm.

Consider a submarine boat or airship moving freely with the direction of the resultant momentum horizontal, and the axis at a slight inclination θ. With no reserve of buoyancy W=W′, and the couple N, tending to increase θ, has the effect of diminishing the metacentric height by h ft. vertical, where

$$Wh\tan\theta=N=(c_2-c_1)\frac{c_1}{c_2}\frac{u^2}{g}\tan\theta, \qquad (6)$$

$$h=\frac{c_2-c_1}{W}\frac{c_1}{c_2}\frac{u^2}{g}=(\beta-\alpha)\frac{1+\alpha}{1+\beta}\frac{u^2}{g}. \qquad (7)$$

51. An elongated shot is made to preserve its axial flight through the air by giving it the spin sufficient for stability, without which it would turn broadside to its advance; a top in the same way is made to stand upright on the point in the position of equilibrium, unstable statically but dynamically stable if the spin is sufficient; and the investigation proceeds in the same way for the two problems (see GYROSCOPE).

The effective angular inertia of the body in the medium is now required; denote it by C_1 about the axis of the figure, and by C_2 about a diameter of the mean section. A rotation about the axis of a figure of revolution does not set the medium in motion, so that C_1 is the moment of inertia of the body about the axis, denoted by Wk_1^2. But if Wk_2^2 is the moment of inertia of the body about a mean diameter, and ω the angular velocity about it generated by an implulse couple M, and M′ is the couple required to set the surrounding medium in motion, supposed of effective radius of gyration k',

$$Wk_2^2\omega=M-M',\ W'k'^2\omega=M', \qquad (1)$$
$$(Wk_2^2+W'k'^2)\omega=M, \qquad (2)$$
$$C_2=Wk_2^2+W'k'^2=(W+W'\epsilon)k_2^2, \qquad (3)$$

in which we have put $k'^2=\epsilon k^2$, where ϵ is a numerical factor depending on the shape.

If the shot is spinning about its axis with angular velocity p, and is precessing steadily at a rate μ about a line parallel to the resultant momentum F at an angle θ, the velocity of the vector of angular momentum, as in the case of a top, is

$$C_1 p\mu \sin\theta - C_2\mu^2 \sin\theta\cos\theta; \tag{4}$$

and equating this to the impressed couple (multiplied by g), that is, to

$$gN = (c_1 - c_2)\frac{c_1}{c_2}u^2 \tan\theta, \tag{5}$$

and dividing out $\sin\theta$, which equated to zero would imply perfect centring, we obtain

$$C_2\mu^2\cos\theta - C_1 p\mu + (c_2 - c_1)\frac{c_1}{c_2}u^2\sec\theta = 0. \tag{6}$$

The least admissible value of p is that which makes the roots equal of this quadratic in μ, and then

$$\mu = \tfrac{1}{2}\frac{C_1}{C_2}p\sec\theta, \tag{7}$$

the roots would be imaginary for a value of p smaller than given by

$$C_1^2 p^2 - 4(c_2 - c_1)\frac{c_1}{c_2}C_2 u^2 = 0, \tag{8}$$

$$\frac{p^2}{u^2} = 4(c_2 - c_1)\frac{c_1}{c_2}\frac{C_2}{C_1^2}. \tag{9}$$

If the shot is moving as if fired from a gun of calibre d inches, in which the rifling makes one turn in a pitch of n calibres or nd inches, so that the angle δ of the rifling is given by

$$\tan\delta = \pi d/nd = \tfrac{1}{2}dp/u, \tag{10}$$

If σ denotes the density of the metal, and if the shell has a cavity homothetic with the external ellipsoidal shape, a fraction f of the linear scale; then the volume of a round shot being $\frac{1}{6}\pi d^3$, and $\frac{1}{6}\pi d^3 x$ of a shot x calibres long

$$W = \tfrac{1}{6}\pi d^3 x(1 - f^3)\sigma, \tag{20}$$

$$Wk_1^2 = \tfrac{1}{6}\pi d^3 x\frac{d^2}{10}(1 - f^5)\sigma, \tag{21}$$

$$Wk_2^2 = \tfrac{1}{6}\pi d^3 x\frac{l^2 + d^2}{20}(1 - f^5)\sigma. \tag{22}$$

If ρ denotes the density of the air or medium

$$W' = \tfrac{1}{6}\pi d^3 x\rho, \tag{23}$$

$$\frac{W'}{W} = \frac{1}{1 - f^3}\frac{\rho}{\sigma}, \tag{24}$$

$$\frac{k_1^2}{d^2} = \frac{1}{10}\frac{1 - f^5}{1 - f^3}, \quad \frac{k_2^2}{k_1^2} = \frac{x^2 + 1}{2}, \tag{25}$$

$$\tan^2\delta = \frac{\rho}{\sigma}(\beta - \alpha)\frac{x^2 + 1}{\frac{1}{5}(1 - f^5)}, \tag{26}$$

in which σ/ρ may be replaced by 800 times the S.G. of the metal, taking water as 800 times denser than air on the average, in round numbers, and formula (10) may be written $n\tan\delta = \pi$, or $n\delta = 180$, when δ is a small angle, and given in degrees.

From this formula (26) the table following has been calculated by A. G. Hadcock, and the results are in agreement with practical experience.

Table of Rifling for Stability of an Elongated Projectile, x *Calibres long, giving* δ *the Angle of Rifling, and* n *the Pitch of Rifling in Calibres.*

		Cast-iron Common Shell $f = \frac{2}{3}$, S.G. 7·2.		Palliser Shell $f = \frac{1}{2}$, S.G. 8.		Solid Steel Bullet $f = 0$, S.G. 8.		Solid Lead Bullet $f = 0$, S.G. 10·9.	
x	$\beta - \alpha$	δ	n	δ	n	δ	n	δ	n
1·0	0·0000	0° 0′	Infinity	0° 0′	Infinity	0° 0′	Infinity	0° 0′	Infinity
2·0	0·4942	2 49	63·87	2 32	71·08	2 29	72·21	2 08	84·29
2·5	0·6056	3 46	47·91	3 23	53·32	3 19	54·17	2 51	63·24
3·0	0·6819	4 41	38·45	4 13	42·79	4 09	43·47	3 38	50·74
3·5	0·7370	5 35	32·13	5 02	35·75	4 58	36·33	4 15	42·40
4·0	0·7782	6 30	27·60	5 51	30·72	5 45	31·21	4 56	36·43
4·5	0·8100	7 24	24·20	6 40	26·93	6 32	27·36	5 37	31·94
5·0	0·8351	8 16	21·56	7 28	23·98	7 21	24·36	6 18	28·44
6·0	0·8721	10 05	17·67	9 04	19·67	8 56	19·98	7 40	23·33
10·0	0·9395	16 57	10·31	15 19	11·47	15 05	11·65	13 00	13·60
Infinity	1·0000	90 00	0·00	90 00	0·00	90 00	0·00	90 00	0·00

which is the ratio of the linear velocity of rotation $\frac{1}{2}dp$ to u, the velocity of advance,

$$\tan^2\delta = \frac{\pi^2}{n^2} = \frac{d^2p^2}{4u^2} = (c_2 - c_1)\frac{c_1}{c_2}\frac{C_2 d^2}{C_1^2}$$

$$= \frac{W'}{W}(\beta - \alpha)\frac{1 + \frac{W'}{W}\alpha}{1 + \frac{W'}{W}\beta}\cdot\frac{\left(1 + \frac{W'}{W}\epsilon\right)\left(\frac{k_2}{d}\right)^2}{\left(\frac{k_1}{d}\right)^4}. \tag{11}$$

For a shot in air the ratio W′/W is so small that the square may be neglected, and formula (11) can be replaced for practical purpose in artillery by

$$\tan^2\delta = \frac{\pi^2}{n^2} = \frac{W'}{W}(\beta - \alpha)\left(\frac{k_2}{d}\right)^2 \Big/ \left(\frac{k_1}{d}\right)^4, \tag{12}$$

if then we can calculate β, α, or $\beta - \alpha$ for the external shape of the shot, this equation will give the value of δ and n required for stability of flight in the air.

The ellipsoid is the only shape for which α and β have so far been determined analytically, as shown already in § 44, so we must restrict our calculation to an egg-shaped bullet, bounded by a prolate ellipsoid of revolution, in which, with $b = c$,

$$A_0 = \int_0^\infty \frac{ab^2 d\lambda}{(a^2 + \lambda)\sqrt{[4(a^2 + \lambda)(b^2 + \lambda)^2]}} = \int_0^\infty \frac{ab^2 d\lambda}{2(a^2 + \lambda)^{3/2}(b^2 + \lambda)}, \tag{13}$$

$$A_0 + 2B_0 = 1, \tag{14}$$

$$\alpha = \frac{A_0}{1 - A_0}, \quad \beta = \frac{B_0}{1 - B_0} = \frac{1 - A_0}{1 + A_0} = \frac{1}{1 + 2\alpha}. \tag{15}$$

The length of the shot being denoted by l and the calibre by d, and the length in calibres by x

$$l/d = 2a/2b = x, \tag{16}$$

$$A_0 = \frac{x}{(x^2 - 1)^{3/2}}\mathrm{ch}^{-1}x - \frac{1}{x^2 - 1}, \tag{17}$$

$$2B_0 = \frac{-x}{(x^2 - 1)^{3/2}}\mathrm{ch}^{-1}x + \frac{x^2}{x^2 - 1}, \tag{18}$$

$$x^2 A_0 + 2B_0 = \frac{x\,\mathrm{sh}^{-1}\sqrt{(x^2 - 1)}}{\sqrt{(x^2 - 1)}} = \frac{x}{\sqrt{(x^2 - 1)}}\log[x + \sqrt{(x^2 - 1)}]. \tag{19}$$

52. In the steady motion the centre of the shot describes a helix, with axial velocity

$$u\cos\theta + v\sin\theta = \left(1 + \frac{c_1}{c_2}\tan^2\theta\right)u\cos\theta \approx u\sec\theta, \tag{1}$$

and transverse velocity

$$u\sin\theta - v\cos\theta = \left(1 - \frac{c_1}{c_2}\right)u\sin\theta \approx (\beta - \alpha)u\sin\theta; \tag{2}$$

and the time of completing a turn of the spiral is $2\pi/\mu$.

When μ has the critical value in (7),

$$\frac{2\pi}{\mu} = \frac{4\pi}{p}\frac{C_2}{C_1}\cos\theta = \frac{2\pi}{p}(x^2 + 1)\cos\theta, \tag{3}$$

which makes the circumference of the cylinder on which the helix is wrapped

$$\frac{2\pi}{\mu}(u\sin\theta - v\cos\theta) = \frac{2\pi u}{p}(\beta - \alpha)(x^2 + 1)\sin^2\theta\cos\theta$$
$$= nd(\beta - \alpha)(x^2 + 1)\sin\theta\cos\theta, \tag{4}$$

and the length of one turn of the helix

$$\frac{2\pi}{\mu}(u\cos\theta + v\sin\theta) = nd(x^2 + 1); \tag{5}$$

thus for $x = 3$, the length is 10 times the pitch of the rifling.

53. *The Motion of a Perforated Solid in Liquid.*—In the preceding investigation, the liquid stops dead when the body is brought to rest; and when the body is in motion the surrounding liquid moves in a uniform manner with respect to axes fixed in the body, and the force experienced by the body from the pressure of the liquid on its surface is the opposite of that required to change the motion of the liquid; this has been expressed by the dynamical equations given above. But if the body is perforated, the liquid can circulate through a hole, in reentrant stream lines linked with the body, even while the body is at rest; and no reaction from the surface can influence this circulation, which may be supposed started in the ideal manner described in § 29, by the application of impulsive pressure across an ideal membrane closing the hole, by means of ideal mechanism connected with the body. The body is held fixed, and the reaction of the mechanism and the resultant of the impulsive pressure on the surface are a measure of the impulse, linear ξ, η, ζ, and angular λ, μ, ν, required to start the circulation.

This impulse will remain of constant magnitude, and fixed relatively to the body, which thus experiences an additional reaction from the circulation which is the opposite of the force required to change the position in space of the circulation impulse; and these extra forces must be taken into account in the dynamical equations.

An article may be consulted in the *Phil. Mag.*, April 1893, by G. H. Bryan, in which the analytical equations of motion are deduced of a perforated solid in liquid, from considerations purely hydrodynamical.

The effect of an external circulation of vortex motion on the motion of a cylinder has been investigated in § 29; a similar procedure will show the influence of circulation through a hole in a solid, taking as the simplest illustration a ring-shaped figure, with uniplanar motion, and denoting by ξ the resultant axial linear momentum of the circulation.

As the ring is moved from O to O′ in time t, with velocity Q, and angular velocity R, the components of liquid momentum change from

$$\alpha M'U + \xi \text{ and } \beta M'V \text{ along } Ox \text{ and } Oy$$

to

$$\alpha M'U' + \xi \text{ and } \beta M'V' \text{ along } O'x' \text{ and } O'y', \qquad (1)$$

the axis of the ring changing from Ox to $O'x'$; and

$$U = Q\cos\theta,\quad V = Q\sin\theta,$$
$$U' = Q\cos(\theta - Rt),\quad V' = Q\sin(\theta - Rt), \qquad (2)$$

so that the increase of the components of momentum, X_1, Y_1, and N_1, linear and angular, are

$$X_1 = (\alpha M'U' + \xi)\cos Rt - \alpha M'U - \xi - \beta M'V'\sin Rt$$
$$= (\alpha - \beta)M'Q\sin(\theta - Rt)\sin Rt - \xi\,\text{ver}\,Rt \qquad (3)$$
$$Y_1 = (\alpha M'U' + \xi)\sin Rt + \beta M'V'\cos Rt - \beta M'V$$
$$= (\alpha - \beta)M'Q\cos(\theta - Rt)\sin Rt + \xi\sin RT, \qquad (4)$$
$$N_1 = [-(\alpha M'U' + \xi)\sin(\theta - Rt) + \beta M'V'\cos(\theta - Rt)]OO'$$
$$= [-(\alpha - \beta)M'Q\cos(\theta - Rt)\sin(\theta - Rt) - \xi\sin(\theta - Rt)]Qt. \qquad (5)$$

The components of force, X, Y, and N, acting on the liquid at O, and reacting on the body, are then

$$X = \text{lt. } X_1/t = (\alpha - \beta)M'QR\sin\theta = (\alpha - \beta)M'VR, \qquad (6)$$
$$Y = \text{lt. } Y_1/t = (\alpha - \beta)M'QR\cos\theta + \xi R = (\alpha - \beta)M'UR + \xi R, \qquad (7)$$
$$Z = \text{lt. } Z_1/t = -(\alpha - \beta)M'Q^2\sin\theta\cos\theta - \xi Q\sin\theta$$
$$= [-(\alpha - \beta)M'U + \xi]V. \qquad (8)$$

Now suppose the cylinder is free; the additional forces acting on the body are the components of kinetic reaction of the liquid

$$-\alpha M'\left(\frac{dU}{dt} - VR\right),\quad -\beta M'\left(\frac{dV}{dt} + UR\right),\quad -\epsilon C'\frac{dR}{dt}, \qquad (9)$$

so that its equations of motion are

$$M\left(\frac{dU}{dt} - VR\right) = -\alpha M'\left(\frac{dU}{dt} - VR\right) - (\alpha - \beta)M'VR, \qquad (10)$$
$$M\left(\frac{dV}{dt} + UR\right) = -\beta M'\left(\frac{dV}{dt} + UR\right) - (\alpha - \beta)M'UR - \xi R, \qquad (11)$$
$$C\frac{dR}{dt} = -\epsilon C'\frac{dR}{dt} + (\alpha - \beta)M'UV + \xi V; \qquad (12)$$

and putting as before

$$M + \alpha M' = c_1,\quad M + \beta M' = c_2,\quad C + \epsilon C' = C_3, \qquad (13)$$
$$c_1\frac{dU}{dt} - c_2 VR = 0, \qquad (14)$$
$$c_2\frac{dV}{dt} + (c_1 U + \xi)R = 0, \qquad (15)$$
$$c_3\frac{dR}{dt} - (c_1 U + \xi - c_2 U)V = 0; \qquad (16)$$

showing the modification of the equations of plane motion, due to the component ξ of the circulation.

The integral of (14) and (15) may be written

$$c_1 U + \xi = F\cos\theta,\quad c_2 V = -F\sin\theta, \qquad (17)$$
$$\frac{dx}{dt} = U\cos\theta - V\sin\theta = \frac{F\cos^2\theta}{c_1} + \frac{F\sin^2\theta}{c_2} - \frac{\xi}{c_1}\cos\theta, \qquad (18)$$
$$\frac{d\mu}{dt} = U\sin\theta + V\cos\theta = \left(\frac{F}{c_1} - \frac{F}{c_2}\right)\sin\theta\cos\theta - \frac{\xi}{c_1}\sin\theta, \qquad (19)$$
$$C_3\frac{d^2\theta}{dt^2} = \left(\frac{F^2}{c_1} - \frac{F^2}{c_2}\right)\sin\theta\cos\theta - \frac{F\xi}{c_1}\sin\theta = F\frac{d\mu}{dt}, \qquad (20)$$
$$C_3\frac{d\theta}{dt} = Fy = \sqrt{\left[-\frac{F^2\cos^2\theta}{c_1} - \frac{F^2\sin^2\theta}{c_2} + 2\frac{F\xi}{c_1}\cos\theta + H\right]}; \qquad (21)$$

so that $\cos\theta$ and y is an elliptic function of the time.

When ξ is absent, dx/dt is always positive, and the centre of the body cannot describe loops; but with ξ, the influence may be great enough to make dx/dt change sign, and so loops occur, as shown in A. B. Basset's *Hydrodynamics*, i. 192, resembling the trochoidal curves, which can be looped, investigated in § 29 for the motion of a cylinder under gravity, when surrounded by a vortex.

The branch of hydrodynamics which discusses wave motion in a liquid or gas is given now in the articles SOUND and WAVE; while the influence of viscosity is considered under HYDRAULICS.

REFERENCES.—For the history and references to the original memoirs see *Report to the British Association*, by G. G. Stokes (1846), and W. M. Hicks (1882). See also the *Fortschritte der Mathematik*, and A. E. H. Love, "Hydrodynamik" in the *Encyklopädie der mathematischen Wissenschaften* (1901). (A. G. G.)

HYDROMEDUSAE, a group of marine animals, recognized as belonging to the Hydrozoa (*q.v.*) by the following characters. (1) The polyp (hydropolyp) is of simple structure, typically much longer than broad, without ectodermal oesophagus or mesenteries, such as are seen in the anthopolyp (see article ANTHOZOA); the mouth is usually raised above the peristome on a short conical elevation or hypostome; the ectoderm is without cilia. (2) With very few exceptions, the polyp is not the only type of individual that occurs, but alternates in the life-cycle of a given species, with a distinct type, the medusa (*q.v.*), while in other cases the polyp-stage may be absent altogether, so that only medusa-individuals occur in the life-cycle.

The Hydromedusae represent, therefore, a sub-class of the Hydrozoa. The only other sub-class is the Scyphomedusae (*q.v.*). The Hydromedusae contrast with the Scyphomedusae in the following points. (1) The polyp, when present, is without the strongly developed longitudinal retractor muscles, forming ridges (*taeniolae*) projecting into the digestive cavity, seen in the scyphistoma or scyphopolyp. (2) The medusa, when present, has a velum and is hence said to be *craspedote*; the nervous system forms two continuous rings running above and below the velum; the margin of the umbrella is not lobed (except in Narcomedusae) but entire; there are characteristic differences in the sense-organs (see below, and SCYPHOMEDUSAE); and gastral filaments (phacellae), subgenital pits, &c., are absent. (3) The gonads, whether formed in the polyp or the medusa, are developed in the ectoderm.

The Hydromedusae form a widespread, dominant and highly differentiated group of animals, typically marine, and found in all seas and in all zones of marine life. Fresh-water forms, however, are also known, very few as regards species or genera, but often extremely abundant as individuals. In the British fresh-water fauna only two genera, *Hydra* and *Cordylophora*, are found; in America occurs an additional genus, *Microhydra*. The paucity of fresh-water forms contrasts sharply with the great abundance of marine genera common in all seas and on every shore. The species of *Hydra*, however, are extremely common and familiar inhabitants of ponds and ditches.

In fresh-water Hydromedusae the life-cycle is usually secondarily simplified, but in marine forms the life-cycle may be extremely complicated, and a given species often passes in the course of its history through widely different forms adapted to different habitats and modes of life. Apart from larval or embryonic forms there are found typically two types of person, as already stated, the polyp and the medusa, each of which may vary independently of the other, since their environment and life-conditions are usually quite different. Hence both polyp and medusa present characters for classification, and a given species, genus or other taxonomic category may be defined by polyp-characters or medusa-characters or by both combined. If our knowledge of the life-histories of these organisms were perfect, their polymorphism would present no difficulties to classification; but unfortunately this is far from being the case. In the majority of cases we do not know the polyp corresponding to a given medusa, or the medusa that arises from a given polyp.[1] Even when a medusa is seen to be budded from a polyp under observation in an aquarium, the difficulty is not always solved, since the freshly-liberated, immature medusa may differ greatly from the full-grown, sexually-mature medusa after several months of life on the high seas (see figs. 11, B,C, and 59, *a*, *b*, *c*). To establish the exact relationship it is necessary not only to breed but to rear the medusa, which cannot always be done in

[1] In some cases hydroids have been reared in aquaria from ova of medusae, but these hydroids have not yet been found in the sea (Browne [10 *a*]).

confinement. The alternative is to fish all stages of the medusa in its growth in the open sea, a slow and laborious method in which the chance of error is very great, unless the series of stages is very complete.

At present, therefore, classifications of the Hydromedusae have a more or less tentative character, and are liable to revision with increased knowledge of the life-histories of these organisms. Many groups bear at present two names, the one representing the group as defined by polyp-characters, the other as defined by medusa-characters. It is not even possible in all cases to be certain that the polyp-group corresponds exactly to the medusa-group, especially in minor systematic categories, such as families.

The following is the main outline of the classification that is adopted in the present article. Groups founded on polyp-characters are printed in ordinary type, those founded on medusa-characters in italics. For definitions of the groups see below.

Sub-class Hydromedusae (*Hydrozoa Craspedota*).

Order I. Eleutheroblastea.
" II. Hydroidea (*Leptolinae*).
Sub-order 1. Gymnoblastea (*Anthomedusae*).
" 2. Calyptoblastea (*Leptomedusae*).
Order III. Hydrocorallinae.
" IV. Graptolitoidea.
" V. *Trachylinae.*
Sub-order 1. *Trachomedusae.*
" 2. *Narcomedusae.*
Order VI. Siphonophora.
Sub-order 1. Chondrophorida.
" 2. Calycophorida.
" 3. Physophorida.
" 4. Cystophorida.

Organization and Morphology of the Hydromedusae.

As already stated, there occur in the Hydromedusae two distinct types of person, the polyp and the medusa; and either of them is capable of non-sexual reproduction by budding, a process which may lead to the formation of colonies, composed of more or fewer individuals combined and connected together. The morphology of the group thus falls naturally into four sections—(1) the hydropolyp, (2) the polyp-colony, (3) the hydromedusa, (4) the medusa-colonies. Since, however, medusa-colonies occur only in one group, the Siphonophora, and divergent views are held with regard to the morphological interpretation of the members of a siphonophore, only the first three of the above sub-divisions of hydromedusa morphology will be dealt with here in a general way, and the morphology of the Siphonophora will be considered under the heading of the group itself.

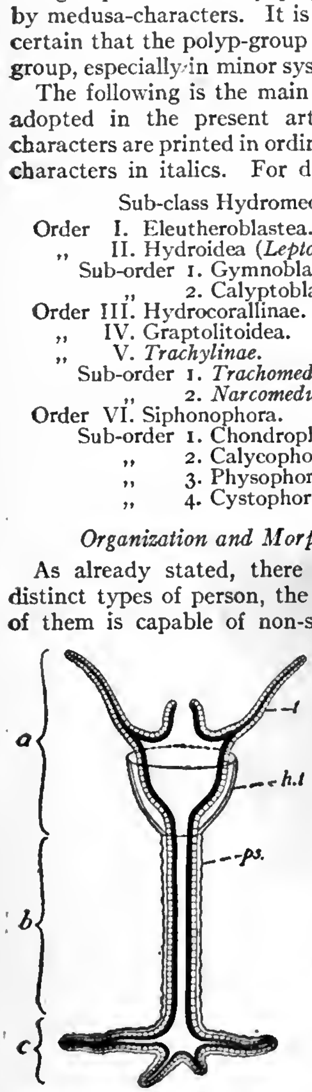

FIG. 1.—Diagram of a typical Hydropolyp.
a, Hydranth;
b, Hydrocaulus;
c, Hydrorhiza;
t, Tentacle;
ps, Perisarc, forming in the region of the hydranth a cup or hydrotheca (*h, t*),—which, however, is only found in polyps of the order Calyptoblastea.

1. *The Hydropolyp* (fig. 1)—The general characters of this organism are described above and in the articles HYDROZOA and POLYP. It is rarely free, but usually fixed and incapable of locomotion. The foot by which it is attached often sends out root-like processes—the *hydrorhiza* (*c*). The column (*b*) is generally long, slender and stalk-like (*hydrocaulus*). Just below the crown of tentacles, however, the body widens out to form a "head," termed the *hydranth* (*a*), containing a stomach-like dilatation of the digestive cavity. On the upper face of the hydranth the crown of tentacles (*t*) surrounds the peristome, from which rises the conical hypostome, bearing the mouth at its extremity. The general ectoderm covering the surface of the body has entirely lost the cilia present in the earlier larval stages (planula), and may be naked, or clothed in a cuticle or exoskeleton, the perisarc (*ps*), which in its simplest condition is a chitinous membrane secreted by the ectoderm. The perisarc when present invests the hydrorhiza and hydrocaulus; it may stop short below the hydranth, or it may extend farther. In general there are two types of exoskeleton, characteristic of the two principal divisions of the Hydroidea. In the Gymnoblastea the perisarc either stops below the hydranth, or, if continued on to it, forms a closely-fitting investment extending as a thin cuticle as far as the bases of the tentacles (*e.g. Bimeria*, see G. J. Allman [1],[1] pl. xii. figs. 1 and 3). In the Calyptoblastea the perisarc is always continued above the

FIG. 2.—*Stauridium productum*, portion of the colony magnified; *p*, polyp; *rh*, hydrorhiza.

hydrocaulus, and forms a cup, the hydrangium or hydrotheca (*h, t*), standing off from the body, into which the hydranth can be retracted for shelter and protection.

The architecture of the hydropolyp, simple though it be, furnishes a long series of variations affecting each part of the body. The greatest variation, however, is seen in the tentacles. As regards number, we find in the aberrant forms *Protohydra* and *Microhydra* tentacles entirely absent. In the curious hydroid *Monobrachium* a single tentacle is present, and the same is the case in *Clathrozoon*; in *Amphibrachium* and in *Lar* (fig. 11, A) the polyp bears two tentacles only. The reduction of the tentacles in all these forms may be correlated with their mode of life, and especially with living in a constant current of water, which brings food-particles always from one direction and renders a complete whorl or circle of tentacles unnecessary. Thus *Microhydra* lives amongst Bryozoa, and appears to utilize the currents produced by these animals. *Protohydra* occurs in oyster-banks and *Monobrachium* also grows on the shells of bivalves, and both these hydroids probably fish in the currents produced by the lamellibranchs. *Amphibrachium* grows in the tissues of a sponge, *Euplectella*, and protrudes its hydranth into the canal-system of the sponge; and *Lar* grows on the tubes of the worm *Sabella*. With the exception of these forms, reduced for the most part in correlation with a semi-parasitic mode of life, the tentacles are usually numerous. It is rare to find in the polyp a regular, symmetrical disposition of the tentacles as in the medusa. The primitive number of four in a whorl is seen, however, in *Stauridium* (fig. 2) and *Cladonema* (Allman [1], pl. xvii.), and in *Clavatella* each whorl consists regularly of eight (Allman, *loc. cit.* pl. xviii.). As a rule, however, the number in a whorl is irregular. The tentacles may form a single whorl, or more than one; thus in *Corymorpha* (fig. 3) and *Tubularia* (fig. 4) there are two circlets; in *Stauridium* (fig. 2) several; in *Coryne* and *Cordylophora* the tentacles are scattered irregularly over the elongated hydranth.

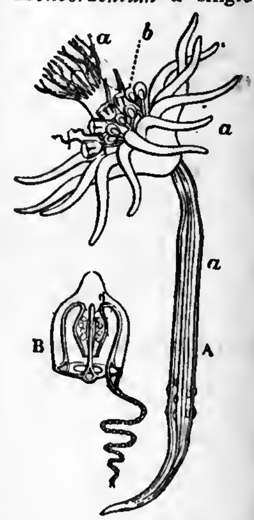

FIG. 3.—Diagram of *Corymorpha*. A, A hydriform person giving rise to medusiform persons by budding from the margin of the disk; B, free swimming medusa (*Steenstrupia* of Forbes) detached from the same, with manubrial genitalia (*Anthomedusae*) and only one tentacle. (After Allman).

As regards form, the tentacles show a number of types, of which the most important are (1) filiform, *i.e.* cylindrical or tapering from

[1] The numbers in square brackets [ ] refer to the bibliography at the end of this article; but when the number is preceded by the word Hydrozoa, it refers to the bibliography at the end of the article HYDROZOA.

base to extremity, as in *Clava* (fig. 5); (2) capitate, *i.e.* knobbed at the extremity, as in *Coryne* (see Allman, *loc. cit.* pl. iv.); (3) branched, a rare form in the polyp, but seen in *Cladocoryne* (see Allman, *loc. cit.* p. 380, fig. 82). Sometimes more than one type of form is found in the same polyp; in *Pennaria* and *Stauridium* (fig. 2) the upper whorls are capitate, the lower filiform. Finally, as regards structure, the tentacles may retain their primitive hollow nature, or become solid by obliteration of the axial cavity.

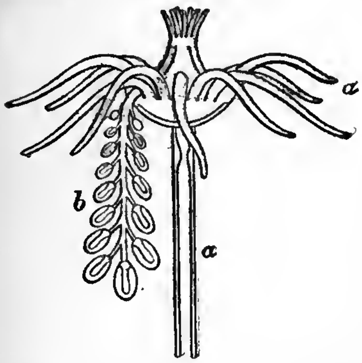

FIG. 4.—Diagram of *Tubularia indivisa*. A single hydriform person *a* bearing a stalk carrying numerous degenerate medusiform persons or sporosacs *b*. (After Allman.)

The hypostome of the hydropolyp may be small, or, on the other hand, as in *Eudendrium* (Allman, *loc. cit.* pls. xiii., xiv.), large and trumpet-shaped. In the curious polyp *Myriothela* the body of the polyp is differentiated into nutritive and reproductive portions.

Histology. — The ectoderm of the hydropolyp is chiefly sensory, contractile and protective in function. It may also be glandular in places. It consists of two regions, an external epithelial layer and a more internal sub-epithelial layer.

The epithelial layer consists of (1) so-called "indifferent" cells secreting the perisarc or cuticle and modified to form glandular cells in places; for example, the adhesive cells in the foot. (2) Sensory cells, which may be fairly numerous in places, especially on the tentacles, but which occur always scattered and isolated, never aggregated to form sense-organs as in the medusa. (3) Contractile

FIG. 5.—Colonies of *Clava*. A, *Clava squamata*, magnified. B, *C. multicornis*, natural size; *p*, *polyp*; *gon*, gonophores; *rh*, hydrorhiza.

or myo-epithelial cells, with the cell prolonged at the base into a contractile muscle-fibre (fig. 6, B). In the hydropolyp the ectodermal muscle-fibres are always directed longitudinally. Belonging primarily to the epithelial layer, the muscular cells may become secondarily sub-epithelial.

The sub-epithelial layer consists primarily of the so-called interstitial cells, lodged between the narrowed basal portions of the epithelial cells. From them are developed two distinct types of histological elements; the genital cells and the cnidoblasts or mother-cells of the nematocysts. The sub-epithelial layer thus primarily constituted may be recruited by immigration from without of other

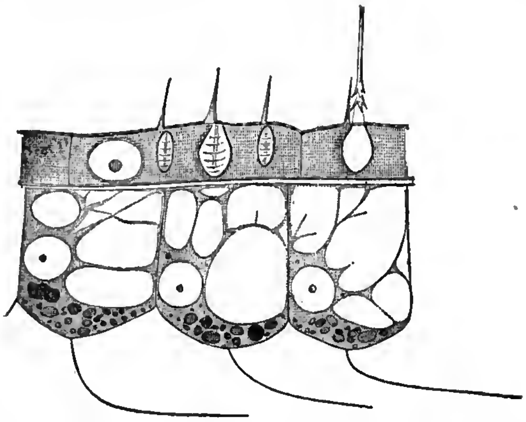

FIG. 6 A.—Portion of the body-wall of *Hydra*, showing ectoderm cells above, separated by "structureless lamella" from three flagellate endoderm cells below. The latter are vacuolated, and contain each a nucleus and several dark granules. In the middle ectoderm cell are seen a nucleus and three nematocysts, with trigger hairs projecting beyond the cuticle. A large nematocyst, with everted thread, is seen in the right-hand ectodermal cell. (After F. E. Schulze.)

elements, more especially by nervous (ganglion) cells and muscle-cells derived from the epithelial layer. In its fullest development, therefore, the sub-epithelial layer consists of four classes of cell-elements.

The genital cells are simple wandering cells (archaeocytes), at first minute and without any specially distinctive features, until they begin to develop into germ-cells. According to Wulfert [60] the primitive germ-cells of *Gonothyraea* can be distinguished soon after the fixation of the planula, appearing amongst the interstitial cells of the ectoderm. The germ-cells are capable of extensive migrations, not only in the body of the same polyp, but also from parent to bud through many non-sexual generations of polyps in a colony (A. Weismann [58]).

The cnidoblasts are the mother-cells of the nematocysts, each cell producing one nematocyst in its interior. The complete nematocyst (fig. 7) is a spherical or oval capsule containing a hollow thread, usually barbed, coiled in its interior. The capsule has a double wall, an outer one (*o.c.*), tough and rigid in nature, and an inner one (*i.c.*) of more flexible consistence. The outer wall of the capsule is incomplete at one pole, leaving an aperture through which the thread is discharged. The inner membrane is continuous with the wall of the hollow thread at a spot immediately below the aperture in the outer wall, so that the thread itself (*f*) is simply a hollow prolongation

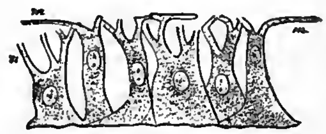

FIG. 6 B.—Epidermo-muscular cells of *Hydra*. *m*, muscular-fibre processes. (After Kleinenberg, from Gegenbaur.)

of the wall of the inner capsule inverted and pushed into its cavity. The entire nematocyst is enclosed in the cnidoblast which formed it. When the nematocyst is completely developed, the cnidoblast passes outwards so as to occupy a superficial position in the ectoderm, and a delicate protoplasmic process of sensory nature, termed the *cnidocil* (*cn*) projects from the cnidoblast like a fine hair or cilium. Many points in the development and mechanism of the nematocyst are disputed, but it is tolerably certain (1) that the cnidocil is of sensory nature, and that stimulation, by contact with prey or in other ways, causes a reflex discharge of the nematocyst; (2) that the discharge is an explosive change whereby the in-turned thread is suddenly everted and turned inside out, being thus shot through the opening in the outer wall of the capsule, and forced violently into the tissues of the prey, or, it may be, of an enemy; (3) that the thread inflicts not merely a mechanical wound, but instils an irritant poison, numbing and paralysing in its action. The points most in dispute are, first, how the explosive discharge is brought about, whether by pressure exerted external to the capsule (*i.e.* by contraction of the cnidoblast) or by internal pressure. N. Iwanzov [27] has brought forward strong grounds for the latter view, pointing out that the cnidoblast has no contractile mechanism and that measurements show discharged capsules to be on the average slightly larger than undischarged ones. He believes that the capsule contains a substance which swells very rapidly when brought into contact with water, and that in the undischarged condition the capsule has its opening closed by a plug of protoplasm (*x*, fig. 7) which prevents access of water to the contents; when the cnidocil is stimulated it sets in action a mechanism or perhaps a series of chemical changes by which the plug is dissolved or removed; as a result water penetrates into the capsule and causes its contents to swell, with the result that the thread is everted violently. A second point of dispute concerns the spot at which the poison is lodged. Iwanzov believes it to be contained within the thread itself before discharge, and to be introduced into the tissues of the prey by the eversion of the thread. A third point of dispute is whether the nematocysts are formed *in situ*, or whether the cnidoblasts migrate with them to the region where they are most needed; the fact that in *Hydra*, for example, there are no interstitial cells in the tentacles, where nematocysts are very abundant, is certainly in favour of the view that the cnidoblasts migrate on to the tentacles from the body, and that like the genital cells the cnidoblasts are wandering cells.

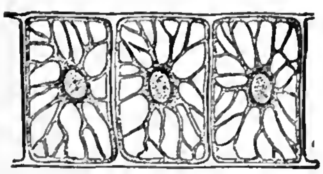
The muscular tissue consists primarily of processes from the bases of the epithelial cells, processes which are contractile in nature and may be distinctly striated. A further stage in evolution is that the muscle-cells lose their connexion with the epithelium and come to lie entirely beneath it, forming a sub-epithelial contractile layer, developed chiefly in the tentacles of the polyp. The evolution of the ganglion-cells is probably similar; an epithelial cell develops processes of nervous nature from the base, which come into connexion with the bases of the sensory cells, with the muscular cells, and with the similar processes of other nerve-cells; next the nerve-cell loses its connexion with the outer epithelium and becomes a sub-epithelial ganglion-cell which is closely connected with the muscular layer, conveying stimuli from the sensory cells to the contractile elements. The ganglion-cells of Hydromedusae are generally very small. In the polyp the nervous tissue is always in the form of a scattered plexus, never concentrated to form a definite nervous system as in the medusa.



From Gegenbaur's *Elements of Comparative Anatomy*.

FIG. 8.—Vacuolated Endoderm Cells of cartilaginous consistence from the axis of the tentacle of a Medusa (*Cunina*).

The endoderm of the polyp is typically a flagellated epithelium of large cells (fig. 6), from the bases of which arise contractile muscular processes lying in the plane of the transverse section of the body. In different parts of the coelenteron the endoderm may be of three principal types—(1) digestive endoderm, the primitive type, with cells of large size and considerably vacuolated, found in the hydranth; some of these cells may become special glandular cells, without flagella or contractile processes; (2) circulatory endoderm, without vacuoles and without basal contractile processes, found in the hydrorhiza and hydrocaulus; (3) supporting endoderm (fig. 8), seen in solid tentacles as a row of cubical vacuolated cells, occupying the axis of the tentacle, greatly resembling notochordal tissue, particularly that of *Amphioxus* at a certain stage of development; as a fourth variety of endodermal cells excretory cells should perhaps be reckoned, as seen in the pores in the foot of *Hydra* and elsewhere (cf. C. Chun, HYDROZOA [1], pp. 314, 315).

The mesogloea in the hydropolyp is a thin elastic layer, in which may be lodged the muscular fibres and ganglion cells mentioned above, but which never contains any connective tissue or skeletogenous cells or any other kind of special mesogloeal corpuscles.

2. *The Polyp-colony.*—All known hydropolyps possess the power of reproduction by budding, and the buds produced may become either polyps or medusae. The buds may all become detached after a time and give rise to separate and independent individuals, as in the common *Hydra*, in which only polyp-individuals are produced and sexual elements are developed upon the polyps themselves; or, on the other hand, the polyp-individuals produced by budding may remain permanently in connexion with the parent polyp, in which case sexual elements are never developed on polyp-individuals but only on medusa-individuals, and a true colony is formed. Thus the typical hydroid colony starts from a "founder" polyp, which in the vast majority of cases is fixed, but which may be floating, as in *Nemopsis*, *Pelagohydra*, &c. The founder-polyp usually produces by budding polyp-individuals, and these in their turn produce other buds. The polyps are all non-sexual individuals whose function is purely nutritive. After a time the polyps, or certain of them, produce by budding medusa-individuals, which sooner or later develop sexual elements; in some cases, however, the founder polyp remains solitary, that is to say, does not produce polyp-buds, but only medusa-buds, from the first (*Corymorpha*, fig. 3, *Myriothela*, &c.). In primitive forms the medusa-individuals are set free before reaching sexual maturity and do not contribute anything to the colony. In other cases, however, the medusa-individuals become sexually mature while still attached to the parent polyp, and are then not set free at all, but become appanages of the hydroid colony and undergo degenerative changes leading to reduction and even to complete obliteration of their original medusan structure. In this way the hydroid colony becomes composed of two portions of different function, the nutritive "trophosome," composed of non-sexual polyps, and the reproductive "gonosome," composed of sexual medusa-individuals, which never exercise a nutritive function while attached to the colony. As a general rule polyp-buds are produced from the hydrorhiza and hydrocaulus, while medusa-buds are formed on the hydranth. In some cases, however, medusa-buds are formed on the hydrorhiza, as in Hydrocorallines.

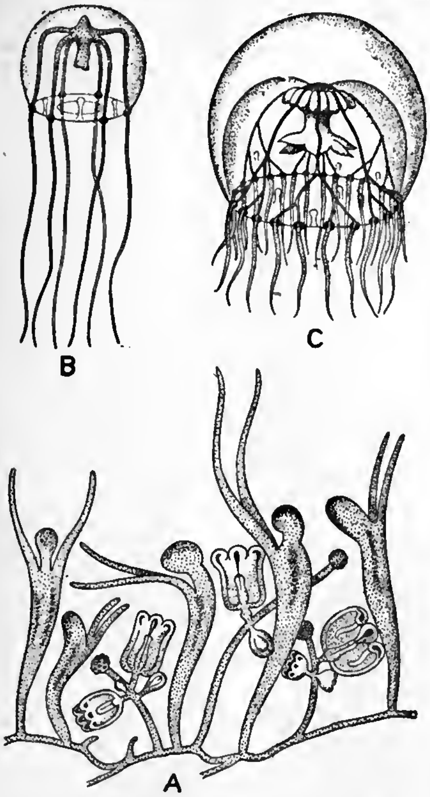
FIG. 10.—Polyps from a Colony of *Hydractinia*, magnified. *dz*, dactylozoid; *gz*, gastrozoid; *b*, blastostyle; *gon*, gonophores; *rh*, hydrorhiza.

In such a colony of connected individuals, the exact limits of the separate "persons" are not always clearly marked out. Hence it is necessary to distinguish between, first, the "zooids," indicated in the case of the polyps by the hydranths, each with mouth and tentacles; and, secondly, the "coenosarc," or common flesh, which cannot be assigned more to one individual than another, but consists of a more or less complicated network of tubes, corresponding to the hydrocaulus and hydrorhiza of the primitive independent polyp-individual. The coenosarc constitutes a system by which the digestive cavity of any one polyp is put into communication with that of any other individual either of the trophosome or gonosome. In this manner the food absorbed by one individual contributes to the welfare of the whole colony, and the coenosarc has the function of circulating and distributing nutriment through the colony.

The hydroid colony shows many variations in form and architecture which depend simply upon differences in the methods in which polyps are budded.



After Hincks, Forbes, and Browne. A and B modified from Hincks; C modified from Forbes's *Brit. Naked-eyed Medusae.*

FIG. 11.—*Lar sabellarum* and two stages of its Medusa, *Willia stellata*. A, colony of *Lar*; B and C, young and adult medusae.

In the first place, buds may be produced only from the hydrorhiza, which grows out and branches to form a basal *stolon*, typically net-like, spreading over the substratum to which the founder-polyp attached itself. From the stolon the daughter-polyps grow up vertically. The result is a spreading or creeping colony, with the coenosarc in the form of a root-like horizontal network (fig. 5, B; 11, A). Such a colony may undergo two principal modifications. The meshes of the basal network may become very small or virtually obliterated, so that the coenosarc becomes a crust of tubes tending to fuse together, and covered over by a common perisarc. Encrusting colonies of this kind are seen in *Clava squamata* (fig. 5, A) and *Hydractinia* (figs. 9, 10), the latter having the perisarc calcified. A further very important modification is seen when the tubes of the basal perisarc do not remain spread out in one plane, but grow in all planes forming a felt-work; the result is a massive colony, such as is seen in the so-called Hydrocorallines (fig. 60), where the interspaces between the coenosarcal tubes are filled up with calcareous matter, or *coenosteum*, replacing the chitinous perisarc. The result is a stony, solid mass, which contributes to the building up of coral reefs. In massive colonies of this kind no sharp distinction can be drawn between hydrorhiza and hydrocaulus in the coenosarc; it is practically all hydrorhiza. Massive colonies may assume various forms and are often branching or tree-like. A further peculiarity of this type of colony is that the entire coenosarcal complex is covered externally by a common layer of ectoderm; it is not clear how this covering layer is developed.

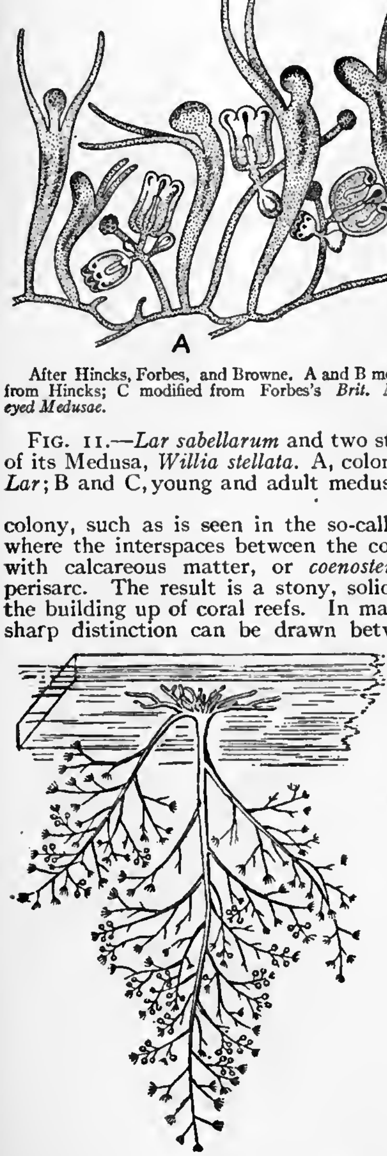


FIG. 12.—Colony of *Bougainvillea fruticosa*, natural size, attached to the underside of a piece of floating timber. (After Allman.)

In the second place, the buds may be produced from the hydrocaulus, growing out laterally from it; the result is an arborescent, tree-like colony (figs. 12, 13). Budding from the hydrocaulus may be combined with budding from the hydrorhiza, so that numerous branching colonies arise from a common basal stolon. In the formation of arborescent colonies, two sharply distinct types of budding are found, which are best described in botanical terminology as the monopodial or racemose, and the sympodial or cymose types respectively; each is characteristic of one of the two sub-orders of the Hydroidea, the Gymnoblastea and Calyptoblastea.

In the monopodial method (figs. 12, 14) the founder-polyp is, theoretically, of unlimited growth in a vertical direction, and as it grows up it throws out buds right and left alternately, so that the first bud produced by it is the lowest down, the second bud is above the first, the third above this again, and so on. Each bud produced

FIG. 13.—Portion of colony of *Bougainvillea fruticosa* (*Anthomedusae-Gymnoblastea*) more magnified. (From Lubbock, after Allman.)

by the founder proceeds to grow and to bud in the same way as the founder did, producing a side branch of the main stem. Hence, in a colony of gymnoblastic hydroids, the oldest polyp of each system, that is to say, of the main stem or of a branch, is the topmost polyp;

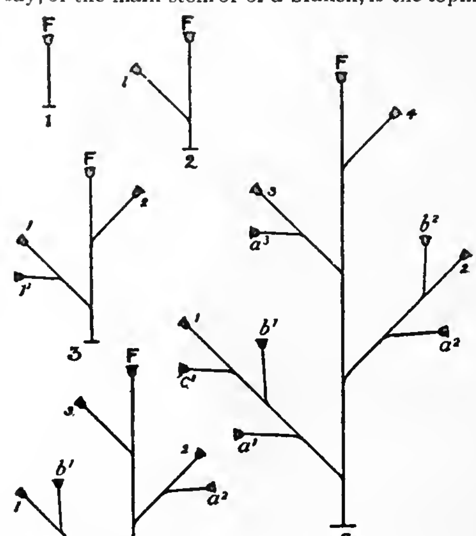

FIG. 14.—Diagrams of the monopodial method of budding, shown in five stages (1-5). F, the founder-polyp; 1, 2, 3, 4, the succession of polyps budded from the founder-polyp; a', b', c', the succession of polyps budded from 1; a^2, b^2, polyps budded from 2; a^3, polyp budded from 3.

the youngest polyp of the system is the one nearest to the topmost polyp; and the axis of the system is a true axis.

In the sympodial method of budding, on the other hand, the founder-polyp is of limited growth, and forms a bud from its side, which is also of limited growth, and forms a bud in its turn, and so on (figs. 15, 16). Hence, in a colony of calyptoblastic hydroids, the oldest polyp of a system is the lowest; the youngest polyp is the topmost one; and the axis of the system is a false axis composed of portions of each of the consecutive polyps. In this method of budding there are two types. In one, the biserial type (fig. 15), the polyps produce buds right and left alternately, so that the hydranths are arranged in a zigzag fashion, forming a "scorpioid cyme," as in *Obelia* and *Sertularia*. In the other, the uniserial type (fig. 16), the buds are formed always on the same side, forming a "helicoid cyme," as in *Hydrallmania*, according to H. Driesch, in which, however, the primitively uniserial arrangement becomes masked later by secondary torsions of the hydranths.

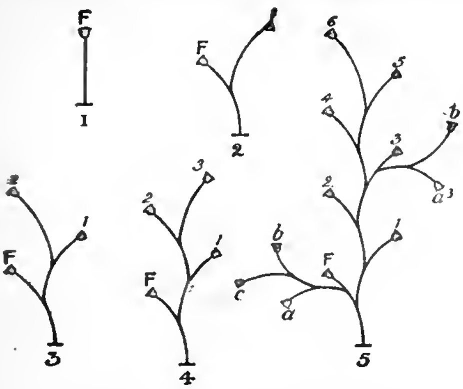

FIG. 15.—Diagram of sympodial budding, biserial type, shown in five stages (1-5). F, founder-polyp; 1, 2, 3, 4, 5, 6, succession of polyps budded from the founder; *a*, *b*, *c*, second series of polyps budded from the founder; a^3, b^3, series budded from 3.

In a colony formed by sympodial budding, a polyp always produces first a bud, which contributes to the system to which it belongs, *i.e.* continues the stem or branch of which its parent forms a part. The polyp may then form a second bud, which becomes the starting point of a new system, the beginning, that is, of a new branch; and even a third bud, starting yet another system, may be produced from the same polyp. Hence the colonies of Calyptoblastea may be complexly branched, and the budding may be biserial throughout, uniserial throughout, or partly one, partly the other. Thus in *Plumularidae* (figs. 17, 18) there is formed a main stem by biserial budding; each polyp on the main stem forms a second bud, which usually forms a side branch or *pinnule* by uniserial budding. In this way are formed the familiar feathery colonies of *Plumularia*, in which the pinnules are all in one plane, while in the allied *Antennularia* the pinnules are arranged in whorls round the main biserial stem. The pinnules never branch again, since in the uniserial mode of budding a polyp never forms a second polyp-bud. On the other hand, a polyp on the main stem may form a second bud which, instead of forming a pinnule by uniserial budding, produces by biserial budding a branch, from which pinnules arise as from the main stem (fig. 18—3, 6). Or a polyp on the main stem, after having budded a second time to form a pinnule, may give rise to a third bud, which starts a new biserial system, from which uniserial pinnules arise as from the main stem—type of *Aglaophenia* (fig. 19). The laws of budding in hydroids have been worked out in an interesting manner by H. Driesch [13], to whose memoirs the reader must be referred for further details.

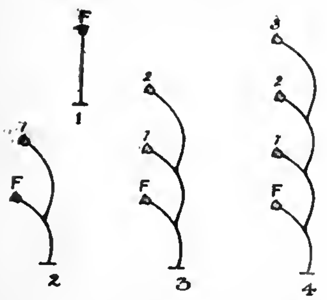

FIG. 16.—Diagram of sympodial budding, uniserial type, shown in four stages (1-4). F, founder-polyp; 1, 2, 3, succession of polyps budded from the founder.

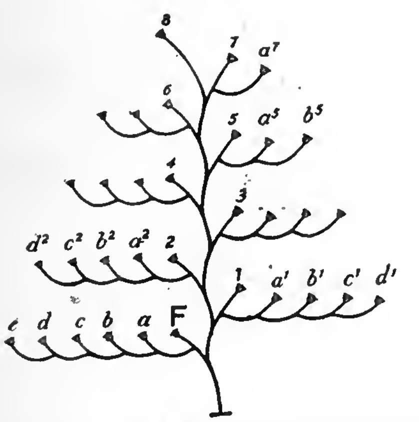

FIG. 17.—Diagram of sympodial budding, simple unbranched *Plumularia*-type. F, founder; 1-8, main axis formed by biserial budding from founder; *a-e*, pinnule formed by uniserial budding from founder; a^1-d^1, branch formed by similar budding from 1; a^2-d^2 from 2, and so forth.

Individualization of Polyp-Colonies.—As in other cases where animal colonies are formed by organic union of separate individuals, there is ever a tendency for the polyp-colony as a whole to act as a single individual, and for the members to become subordinated to the needs of the colony and to undergo specialization for particular functions, with the result that they simulate organs and their individuality becomes masked to a greater or less degree. Perhaps the earliest of such specializations is connected with the reproductive function. Whereas primitively any polyp in a colony may produce medusa-buds, in many hydroid colonies medusae are budded only by certain polyps termed *blastostyles* (fig. 10, *b*). At first not differing in any way from other polyps (fig. 5), the blastostyles gradually lose their nutritive function and the organs connected with it; the mouth and tentacles disappear, and the blastostyle obtains the nutriment necessary for its activity by way of the coenosarc. In the Calyptoblastea, where the polyps are protected by special capsules of the perisarc, the *gonothecae* enclosing the blastostyles differ from the hydrothecae protecting the hydranths (fig. 54).

FIG. 18.—Diagram showing method of branching in the *Plumularia*-type; compare with fig. 17. Polyps 3 and 6, instead of producing uniserial pinnules, have produced biserial branches (3^1, 3^2, 3^3, 3^4; 6^1-6^3), which give off uniserial branches in their turn.

In other colonies the two functions of the nutritive polyp, namely, capture and digestion of food, may be shared between different polyps (fig. 10). One class of polyps, the *dactylozoids* (*dz*), lose their mouth and stomach, and become elongated and tentacle-like, showing great activity of movement. Another class, the *gastrozoids* (*gz*), have the tentacles reduced or absent, but have the mouth and stomach enlarged. The dactylozoids capture food and pass it on to the gastrozoids, which swallow and digest it.

Besides the three types of individual above mentioned, there are other appendages of hydroid colonies, of which the individuality is doubtful. Such are the "guard-polyps" (machopolyps) of *Plumularidae*, which are often regarded as individuals of the nature of dactylozoids, but from a study of the mode of budding in this hydroid family Driesch concluded that the guard-polyps were not true polyp-individuals, although each is enclosed in a small protecting cup of the perisarc, known as a nematophore. Again, the spines arising from the basal crust of *Podocoryne* have been interpreted by some authors as reduced polyps.

3. *The Medusa.*—In the Hydromedusae the medusa-individual occurs, as already stated, in one of two conditions, either as an independent organism leading a true life in the open seas, or as a subordinate individuality in the hydroid colony, from which it is never set free; it then becomes a mere reproductive appendage or *gonophore*, losing successively its organs of sense, locomotion and nutrition, until its medusoid nature and organization become scarcely recognizable. Hence it is convenient to consider the morphology of the medusa from these two aspects.

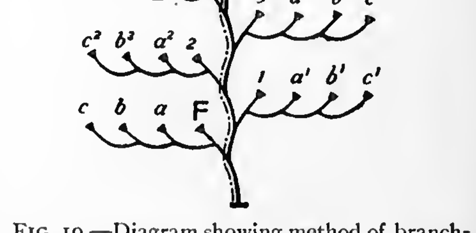

FIG. 19.—Diagram showing method of branching in the *Aglaophenia*-type. Polyp 7 has produced as its first bud, 8; as its second bud, a^7, which starts a uniserial pinnule; and as a third bud I^7, which starts a biserial branch (II^7-VI^7) that repeats the structure of the main stem and gives off pinnules. The main stem is indicated by —·—·—, the new stem by ······.

(*a*) *The Medusa as an Independent Organism.*—The general structure and characteristics of the medusa are described elsewhere (see articles HYDROZOA and MEDUSA), and it is only necessary here to deal with the peculiarities of the Hydromedusa.

As regards habit of life the vast majority of Hydromedusae are pelagic organisms, floating on the surface of the open sea, propelling themselves feebly by the pumping movements of the umbrella produced by contraction of the sub-umbral musculature, and capturing their prey with their tentacles. The genera *Cladonema* (fig. 20) and *Clavatella* (fig. 21), however, are ambulatory, creeping forms, living in rock-pools and walking, as it were, on the tips of the proximal branches of each of the tentacles, while the remaining branches serve for capture of food. *Cladonema* still has the typical medusan structure, and is able to swim about, but in *Clavatella* the umbrella is so much reduced that swimming is no longer possible. The remarkable medusa *Mnestra parasites* is ecto-parasitic throughout life on the pelagic mollusc *Phyllirrhoe*, attached to it by the sub-umbral surface, and its tentacles have become rudimentary or absent. It is interesting to note that *Mnestra* has been shown by J. W. Fewkes [15] and R. T. Günther [19] to belong to the same family (*Cladonemidae*) as *Cladonema* and *Clavatella*, and it is reasonable to suppose that the non-parasitic ancestor of *Mnestra* was, like the other two genera, an ambulatory medusa which acquired louse-like habits. In some species of the genus *Cunina* (Narcomedusae) the youngest individuals (actinulae) are parasitic on other medusae (see below), but in later life the parasitic habit is abandoned. No other instances are known of sessile habit in Hydromedusae.

FIG. 21.—*Clavatella prolifera*, ambulatory medusa. *t*, tentacles; *oc*, ocelli.

The external form of the Hydromedusae varies from that of a deep bell or thimble, characteristic of the Anthomedusae, to the shallow saucer-like form characteristic of the Leptomedusae. It is usual for the umbrella to have an even, circular, uninterrupted margin; but in the order Narcomedusae secondary down-growths between the tentacles produce a lobed, indented margin to the umbrella. The marginal tentacles are rarely absent in non-parasitic forms, and are typically four in number, corresponding to the four perradii marked by the radial canals. Interradial tentacles may be also developed, so that the total number present may be increased to eight or to an indefinitely large number. In *Willia*, *Geryonia*, &c., however, the tentacles and radial canals are on the plan of six instead of four (figs. 11 and 26). On the other hand, in some cases the tentacles are less in number than the perradii; in *Corymorpha* (figs. 3 and 22) there is but a single tentacle, while two are found in *Amphinema* and *Gemmaria* (Anthomedusae), and in *Solmundella bitentaculata* (fig. 67) and *Aeginopsis hensenii* (fig. 23) (Narcomedusae). The tentacles also vary considerably in other ways than in number: first, in form, being usually simple, with a basal bulb, but in *Cladonemidae* they are branched, often in complicated fashion; secondly, in grouping, being usually given off singly, and at regular intervals from the margin of the umbrella, but in *Margelidae* and in some Trachomedusae they are given off in tufts or bunches (fig. 24); thirdly, in position and origin, being usually implanted on the extreme edge of the umbrella, but in Narcomedusae they become secondarily shifted and are given off high up on the ex-umbrella (figs. 23 and 25); and, fourthly, in structure, being hollow or solid, as in the polyp. In some medusae, for instance, the remarkable deep-sea family *Pectyllidae*, the tentacles may bear suckers, by which the animal may attach itself temporarily. It should be mentioned finally that the tentacles are very contractile and extensible, and may therefore present themselves, in one and the same individual, as long, drawn-out threads, or in the form of short corkscrew-like ringlets; they may stream downwards from the sub-umbrella, or be held out horizontally, or be directed upwards over the ex-umbrella (fig. 23). Each species of medusa usually has a characteristic method of carrying its tentacles.

FIG. 24.—*Rathkea octonemalis.*

The sub-umbrella invariably shows a velum as an inwardly projecting ridge or rim at its margin, within the circle of tentacles; hence the medusae of this sub-class are termed craspedote. The manubrium is absent altogether in the fresh-water medusa *Limnocnida*, in which the diameter of the mouth exceeds half that of the umbrella; on the other hand, the manubrium may attain a great length, owing to the centre of the sub-umbrella with the stomach being drawn into it, as it were, to form a long proboscis, as in *Geryonia*. The mouth may be a simple, circular pore at the extremity of the manubrium, or by folding of the edges it may become square or shaped like a Maltese cross, with four corners and four lips. The corners of the mouth may then be drawn out into lobes or lappets, which may have a branched or fringed outline (fig. 27), and in *Margelidae* the subdivisions of the fringe simulate tentacles (fig. 24).

The internal anatomy of the Hydromedusae shows numerous variations. The stomach may be altogether lodged in the manubrium, from which the radial canals then take origin directly as in *Geryonia* (Trachomedusae); it may be with or without gastric pouches. The radial canals may be simple or branched, primarily four, rarely six in number. The ring-canal is drawn out in Narcomedusae into festoons corresponding with the lobes of the margin, and may be obliterated altogether (*Solmaris*). In this order the radial canals are represented only by wide gastric pouches, and in the family Solmaridae are suppressed altogether, so that the tentacles and the festoons of the ring-canal arise directly from the stomach. In *Geryonia*, centripetal canals, ending blindly, arise from the ring-canal and run in a radial direction towards the centre of the umbrella (fig. 26).

FIG. 25.—*Aeginura grimaldii*, natural size.

Histology of the Hydromedusa.—The histology described above for the polyp may be taken as the primitive type, from which that of the medusa differs only in greater elaboration and differentiation of the cell-elements, which are also more concentrated to form distinct tissues.

The ectoderm furnishes the general epithelial covering of the body, and the muscular tissue, nervous system and sense-organs. The

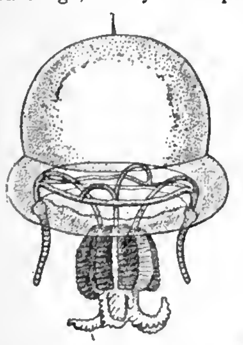
external epithelium is flat on the ex-umbral surface, more columnar on the sub-umbral surface, where it forms the muscular tissue of the sub-umbrella and the velum. The nematocysts of the ectoderm may be grouped to form batteries on the tentacles, umbrellar margin and oral lappets. In places the nematocysts may be crowded so thickly as to form a tough, supporting, "chondral" tissue, resembling cartilage, chiefly developed at the margin of the umbrella and forming streaks or bars supporting the tentacles ("Tentakelspangen," *peronia*) or the tentaculocysts ("Gehorspangen," *otoporpae*).



After O. Maas in *Results of the "Albatross" Expedition*, Museum of Comparative Zoology, Cambridge, Mass., U.S.A.

FIG. 27.—*Stomotoca divisa*, one of the *Tiaridae* (Anthomedusae).

The muscular tissue of the Hydromedusae is entirely ectodermal. The muscle-fibres arise as processes from the bases of the epithelial cells; such cells may individually become sub-epithelial in position, as in the polyp; or, in places where muscular tissue is greatly developed, as in the velum or sub-umbrella, the entire muscular epithelium may be thrown into folds in order to increase its surface, so that a deeper sub-epithelial muscular layer becomes separated completely from a more superficial body-epithelium.

In its arrangement the muscular tissue forms two systems: the one composed of striated fibres arranged circularly, that is to say, concentrically round the central axis of the umbrella; the other of non-striated fibres running longitudinally, that is to say, in a radial direction from, or (in the manubrium) parallel to, the same ideal axis. The circular system is developed continuously over the entire sub-umbral surface, and the velum represents a special local development of this system, at a region where it is able to act at the greatest mechanical advantage in producing the contractions of the umbrella by which the animal progresses. The longitudinal system is discontinuous, and is subdivided into proximal, medial and distal portions. The proximal portion forms the retractor muscles of the manubrium, or proboscis, well developed, for example, in *Geryonia*. The medial portion forms radiating tracts of fibres, the so-called "bell-muscles" running underneath, and parallel to, the radial canals; when greatly developed, as in *Tiaridae*, they form ridges, so-called mesenteries, projecting into the sub-umbral cavity. The distal portions form the muscles of the tentacles. In contrast with the polyp, the longitudinal muscle-system is entirely ectodermal, there being no endodermal muscles in craspedote medusae.

The nervous system of the medusa consists of sub-epithelial ganglion-cells, which form, in the first place, a diffuse plexus of nervous tissue, as in the polyp, but developed chiefly on the sub-umbral surface; and which are concentrated, in the second place, to form a definite central nervous system, never found in the polyp. In Hydromedusae the central nervous system forms two concentric nerve-rings at the margin of the umbrella, near the base of the velum. One, the "upper" or ex-umbral nerve-ring, is derived from the ectoderm on the ex-umbral side of the velum; it is the larger of the two rings, containing more numerous but smaller ganglion-cells, and innervates the tentacles. The other, the "lower" or sub-umbral nerve-ring, is derived from the ectoderm on the sub-umbral side of the velum; it contains fewer but larger ganglion-cells and innervates the muscles of the velum (see diagram in article MEDUSAE). The two nerve-rings are connected by fibres passing from one to the other.

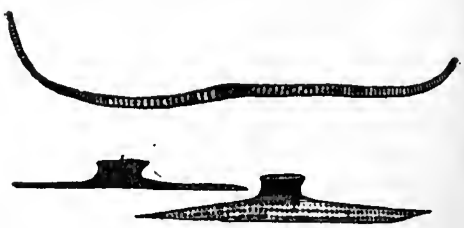


FIG. 28.—Muscular Cells of Medusae (*Lizzia*). The uppermost is a purely muscular cell from the sub-umbrella; the two lower are epidermo-muscular cells from the base of a tentacle; the upstanding nucleated portion forms part of the epidermal mosaic on the free surface of the body. (After Hertwig.)

The sensory cells are slender epithelial cells, often with a cilium or stiff protoplasmic process, and should perhaps be regarded as the only ectoderm-cells which retain the primitive ciliation of the larval ectoderm, otherwise lost in all Hydrozoa. The sense-cells form, in the first place, a diffuse system of scattered sensory cells, as in the polyp, developed chiefly on the manubrium, the tentacles and the margin of the umbrella, where they form a sensory ciliated epithelium covering the nerve-centres; in the second place, the sense-cells are concentrated to form definite sense-organs, situated always at the margin of the umbrella, hence often termed "marginal bodies." The possession of definite sense-organs at once distinguishes the medusa from the polyp, in which they are never found.

The sense-organs of medusae are of two kinds—first, organs sensitive to light, usually termed *ocelli* (fig. 29); secondly, organs commonly termed *otocysts*, on account of their resemblance to the auditory vesicles of higher animals, but serving for the sense of balance and orientation, and therefore given the special name of *statocysts* (fig. 30). The sense-organs may be *tentaculocysts*, *i.e.* modifications of a tentacle, as in Trachylinae, or developed from the margin of the umbrella, in no connexion with a tentacle (or, if so connected, not producing any modification in the tentacle), as in Leptolinae. In Hydromedusae the sense-organs are always exposed at the umbrellar margin (hence *Gymnophthalmata*), while in Scyphomedusae they are covered over by flaps of the umbrellar margin (hence *Steganophthalmata*).

FIG. 29.—*Tiaropsis rosea* (Ag. and Mayer) showing the eight adradial Statocysts, each close to an Ocellus. Cf. fig. 30.

The *statocysts* present in general the structure of either a knob or a closed vesicle, composed of (1) indifferent supporting epithelium; (2) sensory, so-called auditory epithelium of slender cells, each bearing at its free upper end a stiff bristle and running out at its base into a nerve-fibre; (3) concrement-cells, which produce intercellular concretions, so-called otoliths. By means of vibrations or shocks transmitted through the water, or by displacements in the balance or position of the animal, the otoliths are caused to impinge against the bristles of the sensory cells, now on one side, now on the other, causing shocks or stimuli which are transmitted by the basal nerve-fibre to the central nervous system. Two stages in the development of the otocyst can be recognized, the first that of an open pit on a freely-projecting knob, in which the otoliths are exposed, the second that of a closed vesicle, in which the otoliths are covered over. Further, two distinct types of otocyst can be recognized in the Hydromedusae; that of the Leptolinae, in which the entire organ is ectodermal, concrement-cells and all, and the organ is not a tentaculocyst; and that of the Trachylinae, in which the organ is a tentaculocyst, and the concrement-cells are endodermal, derived from the endoderm of the modified tentacle, while the rest of the organ is ectodermal.

In the Leptolinae the otocysts are seen in their first stage in *Mitrocoma annae* (fig. 31) and *Tiaropsis* (figs. 29, 30) as an open pit at the base of the velum, on its sub-umbral side. The pit has its opening turned towards the sub-umbral cavity, while its base or *fundus* forms a bulge, more or less pronounced, on the ex-umbral side of the velum. At the fundus are placed the concrement-cells with their conspicuous otoliths (*con*) and the inconspicuous auditory cells, which are connected with the sub-umbral nerve-ring. From the open condition arises the closed condition very simply by closing up of the aperture of the pit. We then find the typical otocyst of the Leptomedusae, a vesicle bulging on the ex-umbral side of the velum (figs. 32, 33). The otocysts are placed on the outer wall of the vesicle (the fundus of the original pit) or on its sides; their arrangement and number vary greatly and furnish useful characters for distinguishing genera. The sense-cells are innervated, as before, from the sub-umbral nerve-ring. The inner wall of the vesicle

(region of closure) is frequently thickened to form a so-called "sense-cushion," apparently a ganglionic offshoot from the sub-umbral nerve-ring. In many Leptomedusae the otocysts are very small, inconspicuous and embedded completely in the tissues; hence they may be easily overlooked in badly-preserved material, and perhaps are present in many cases where they have been said to have been wanting.

In the Trachylinae the simplest condition of the otocyst is a freely projecting club, a so-called *statorhabd* (figs. 34, 35), representing a tentacle greatly reduced in size, covered with sensory ectodermal epithelium (*ect.*), and containing an endodermal core (*end.*), which is at first continuous with the endoderm of the ring-canal, but later becomes separated from it. In the endoderm large concretions are formed (*con.*). Other sensory cells with long cilia cover a sort of cushion (*n.c.*) at the base of the club; the club may be long and the cushion small, or the cushion large and the club small. The whole structure is innervated, like the tentacles, from the ex-umbral nerve-ring. An advance towards the second stage is seen in such a form as *Rhopalonema* (fig. 36), where the ectoderm of the cushion rises up in a double fold to enclose the club in a protective covering forming a cup or vesicle, at first open distally; finally the opening closes and the closed vesicle may sink inwards and be found far removed from the surface, as in *Geryonia* (fig. 37).

The *ocelli* are seen in their simplest form as a pigmented patch of ectoderm, which consists of two kinds of cells—(1) pigment-cells, which are ordinary indifferent cells of the epithelium containing pigment-granules, and (2) visual cells, slender sensory epithelial cells of the usual type, which may develop visual cones or rods at their free extremity. The ocelli occur usually either on the inner or outer sides of the tentacles; if on the inner side, the tentacle is turned upwards and carried over the ex-umbrella, so as to expose the ocellus to the light; if the ocellus be on the outer side of a tentacle, two nerves run round the base of the tentacle to it. In other cases ocelli may occur between tentacles, as in *Tiaropsis* (fig. 29).

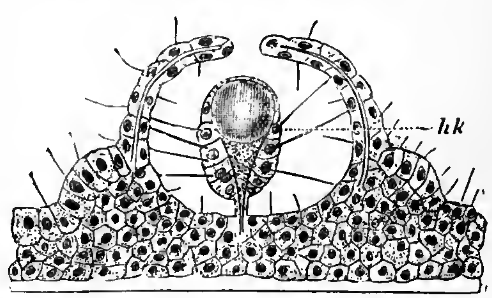

FIG. 36.—Simple tentaculocyst of *Rhopalonema velatum*. The process carrying the otolith or concretion *hk*, formed by endoderm cells, is enclosed by an upgrowth forming the "vesicle," which is not yet quite closed in at the top. (After Hertwig.)

The simple form of ocellus described in the foregoing paragraph may become folded into a pit or cup, the interior of which becomes filled with a clear gelatinous secretion forming a sort of vitreous body. The distal portion of the vitreous body may project from the cavity of the cup, forming a non-cellular lens as in *Lizzia* (fig. 28). Beyond this simple condition the visual organs of the Hydromedusae do not advance, and are far from reaching the wonderful development of the eyes of Scyphomedusae (*Charybdaea*).

Besides the ordinary type of ocellus just described, there is found in one genus (*Tiaropsis*) a type of ocellus in which the visual elements are inverted, and have their cones turned away from the light, as in the human retina (fig. 30). In this case the pigment-cells are endodermal, forming a cup of pigment in which the visual cones are embedded. A similar ocellus is formed in *Aurelia* among the Scyphomedusae (*q.v.*).

Other sense organs of Hydromedusae are the so-called *sense-clubs* or *cordyli* found in a few Leptomedusae, especially in those genera in which otocysts are inconspicuous or absent (fig. 39). Each cordylus is a tentacle-like structure with an endodermal axis containing an axial cavity which may be continuous with the ring-canal, or may be partially occluded. Externally the cordylus is covered by very flattened ectoderm, and bears no otoliths or sense-cells, but the base of the club rests upon the ex-umbral nerve-ring. Brooks regards these organs as sensory, serving for the sense of balance, and representing a primitive stage of the tentaculocysts of Trachylinae; Linko, on the other hand, finding no nerve-elements connected with them, regards them as digestive (?) in function.

The sense-organs of the two fresh-water medusae *Limnocodium* and *Limnocnida* are peculiar and of rather doubtful nature (see E. T. Browne [**10**]).

The endoderm of the medusa shows the same general types of structure as in the polyp, described above. We can distinguish (1) digestive endoderm, in the stomach, often with special glandular elements; (2) circulatory endoderm, in the radial and ring-canals; (3) supporting endoderm in the axes of the tentacles and in the endoderm-lamella; the latter is primitively a double layer of cells, produced by concrescence of the ex-umbral and sub-umbral layers of the coelenteron, but it is usually found as a single layer of flattened cells (fig. 40); in *Geryonia*, however, it remains double, and the centripetal canals arise by parting of the two layers; (4) excretory endoderm, lining pores at the margin of the umbrella, occurring in certain Leptomedusae as so-called "marginal tubercles," opening, on the one hand, into the ring-canal and, on the other hand, to the exterior by "marginal funnels," which debouch into the sub-umbral cavity above the velum. As has been described above, the endoderm may also contribute to the sense-organs, but such contributions are always of an accessory nature, for instance, concrement-cells in the otocysts, pigment in the ocelli, and never of sensory nature, sense-cells being in all cases ectodermal.

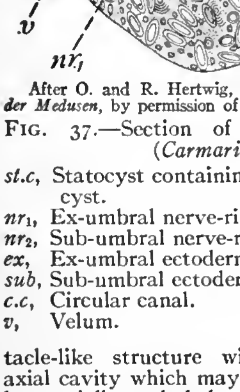

FIG. 38.—Ocellus of *Lizzia koellikeri*. *oc*, Pigmented ectodermal cells; *l*, lens. (After Hertwig.)

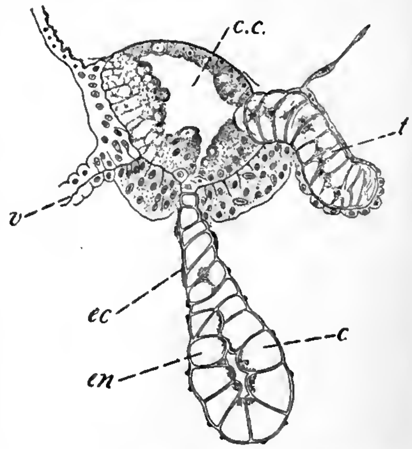
The reproductive cells may be regarded as belonging primarily to neither ectoderm nor endoderm, though lodged in the ectoderm in all Hydromedusae. As described for the polyp, they are wandering cells capable of extensive migrations before reaching the particular spot at which they ripen. In the Hydromedusae they usually, if not invariably, ripen in the ectoderm, but in the neighbourhood of the main sources of nutriment, that is to say, not far from the stomach. Hence the gonads are found on the manubrium in Anthomedusae generally; on the base of the manubrium, or under the gastral pouches, or in both these situations (*Octorchidae*), or under the radial canals, in Trachomedusae; under the gastral pouches or radial canals, in Narcomedusae. When ripe, the germ-cells are dehisced directly to the exterior.

Hydromedusae are of separate sexes, the only known exception being *Amphogona apsteini*, one of the Trachomedusae (Browne [**9**]). Moreover, all the medusae budded from a given hydroid colony are either male or female, so that even the non-sexual polyp must be considered to have a latent sex. (In *Hydra*, on the other hand, the individual is usually hermaphrodite.) The medusa always reproduces itself sexually, and in some cases non-sexually also. The non-sexual reproduction takes the form of fission, budding or sporogony, the details of which are described below. Buds may be produced from the manubrium, radial canals, ring-canal, or tentacle-bases, or from an aboral stolon (Narcomedusae). In all cases only medusa-buds are produced, never polyp-buds.



After W. K. Brooks, *Journal of Morphology*, x., by permission of Ginn & Co.

FIG. 39.—Section of a Cordylus of *Laodice*.

c.c, Circular canal.
v, Velum.
t, Tentacle.
c, Cordylus, composed of flattened ectoderm *ec* covering a large-celled endodermal axis *en*.

The mesogloea of the medusa is largely developed and of great thickness in the umbrella. The sub-epithelial tissues, *i.e.* the nervous and muscular cells, are lodged in the mesogloea, but in Hydromedusae it never contains tissue-cells or mesogloeal corpuscles.

(*b*) *The Medusae as a Subordinate Individuality.*—It has been shown above that polyps are budded only from polyps and that the medusae may be budded either from polyps or from medusae. In any case the daughter-individuals produced from the buds may be imagined as remaining attached to the parent and forming a colony of individuals in organic connexion with one another, and thus three possible cases arise. The first case gives a colony entirely composed of polyps, as in many Hydroidea. The second case gives a colony partly composed of polyp-individuals, partly of medusa-individuals, a possibility also realized in many colonies of Hydroidea. The third case gives a colony entirely composed of medusa-individuals, a possibility perhaps realized in the Siphonophora, which will be discussed in dealing with this group.

The first step towards the formation of a mixed hydroid colony is undoubtedly a hastening of the sexual maturity of the medusa-individual. Normally the medusae are liberated in quite an immature state; they swim away, feed, grow and become adult mature individuals. From the bionomical point of view, the medusa is to be considered as a means of spreading the species, supplementing the deficiencies of the sessile polyp. It may be, however, that increased reproductiveness becomes of greater importance to the species than wide diffusion; such a condition will be brought about if the medusae mature quickly and are either set free in a mature condition or remain in the shelter of the polyp-colony, protected from risks of a free life in the open sea. In this way the medusa sinks from an independent personality to an organ of the polyp-colony, becoming a so-called *medusoid gonophore*, or bearer of the reproductive organs, and losing gradually all organs necessary for an independent existence, namely those of sense, locomotion and nutrition.

en, Endoderm lining the enteric cavity.
e, Wandering endoderm cells of the gelatinous substance.

In some cases both free medusae and gonophores may be produced from the same hydroid colony. This is the case in *Syncoryne mirabilis* (Allman [**1**], p. 278) and in *Campanularia volubilis*; in the latter, free medusae are produced in summer, gonophores in winter (Duplessis [**14**]). Again in *Pennaria*, the male medusae are set free in a state of maturity, and have ocelli; the female medusae remain attached and have no sense organs.

The gonophores of different hydroids differ greatly in structure from one another, and form a series showing degeneration of the medusa-individual, which is gradually stripped, as it were, of its characteristic features of medusan organization and finally reduced to the simplest structure. A very early stage in the degeneration is well exemplified by the so-called "meconidium" of *Gonothyraea* (fig. 41, A). Here the medusoid, attached by the centre of its ex-umbral surface, has lost its velum and sub-umbral muscles, its sense organs and mouth, though still retaining rudimentary tentacles. The gonads (*g*) are produced on the manubrium, which has a hollow endodermal axis, termed the spadix (*sp.*), in open communication with the coenosarc of the polyp-colony and serving for the nutrition of the generative cells. A very similar condition is seen in *Tubularia* (fig. 41, B), where, however, the tentacles have quite disappeared, and the circular rim formed by the margin of the umbrella has nearly closed over the manubrium leaving only a small aperture through which the embryos emerge. The next step is illustrated by the female gonophores of *Cladocoryne*, where the radial and ring-canals

have become obliterated by coalescence of their walls, so that the entire endoderm of the umbrella is in the condition of the endoderm-lamella. Next the opening of the umbrella closes up completely and disappears, so that the sub-umbral cavity forms a closed space surrounding the manubrium, on which the gonads are developed; such a condition is seen in the male gonophore of *Cladocoryne* and in *Garveia* (fig. 41, C), where, however, there is a further complication in the form of an adventitious envelope or ectotheca (*ect.*) split off from the gonophore as a protective covering, and not present in *Cladocoryne*. The sub-umbral cavity (*s.c.*) functions as a brood-space for the developing embryos, which are set free by rupture of the wall. It is evident that the outer envelope of the gonophore represents the ex-umbral ectoderm (*ex.*), and that the inner ectoderm lining the cavity represents the sub-umbral ectoderm of the free medusa. The next step is the gradual obliteration of the sub-umbral cavity (*s.c.*) by disappearance of which the sub-umbral ectoderm comes into contact with the ectoderm of the manubrium. Such a type is found in *Plumularia* and also in *Agalma* (fig. 41, D); centrally is seen the spadix (*sp.*), bearing the generative cells (*g*), and external to these (1) a layer of ectoderm representing the epithelium of the manubrium; (2) the layer of sub-umbral ectoderm; (3) the endoderm-lamella (*e.l.*); (4) the ex-umbral ectoderm (*ex.*); and (5) there may or may not be present also an ectotheca. Thus the gonads are covered over by at least four layers of epithelium, and since these are unnecessary, presenting merely obstacles to the dehiscence of the gonads, they gradually undergo reduction. The sub-umbral ectoderm and that covering the manubrium undergo concrescence to form a single layer (fig. 41, E), which finally disappears altogether, and the endoderm-lamella disappears. The gonophore is now reduced to its simplest condition, known as the *sporosac* (fig. 41, F, G, H), and consists of the spadix bearing the gonads covered by a single layer of ectoderm (*ex.*), with or without the addition of an ectotheca. It cannot be too strongly emphasized, however, that the sporosac should not be compared simply with the manubrium of the medusa, as is sometimes done. The endodermal spadix (*sp*) of the sporosac represents the endoderm of the manubrium; the ectodermal lining of the sporosac (*ex.*) represents the ex-umbral ectoderm of the medusa; and the intervening layers, together with the sub-umbral cavity, have disappeared. The spadix, as the organ of nutrition for the gonads, may be developed in various ways, being simple (fig. 41, F) or branched (fig. 41, H); in *Eudendrium* (fig. 41, G) it curls round the single large ovum.

The hydroid *Dicoryne* is remarkable for the possession of gonophores, which are ciliate and become detached and swim away by means of their cilia. Each such sporosac has two long tentacle-like processes thickly ciliated.

It has been maintained that the gonads of *Hydra* represent sporosacs or gonophores greatly reduced, with the last traces of medusoid structure completely obliterated. There is, however, no evidence whatever for this, the gonads of *Hydra* being purely ectodermal structures, while all medusoid gonophores have an endodermal portion. *Hydra* is, moreover, bisexual, in contrast with what is known of hydroid colonies.

In some Leptomedusae the gonads are formed on the radial canals and form protruding masses resembling sporosacs superficially, but not in structure. Allman, however, regarded this type of gonad as equivalent to a sporosac, and considered the medusa bearing them as a non-sexual organism, a "blastocheme" as he termed it, producing by budding medusoid gonophores. As medusae are known to bud medusae from the radial canals there is nothing impossible in Allman's theory, but it cannot be said to have received satisfactory proof.

Reproduction and Ontogeny of the Hydromedusae.

Nearly every possible method of reproduction occurs amongst the Hydromedusae. In classifying methods of generation it is usual to make use of the sexual or non-sexual nature of the reproduction as a primary difference, but a more scientific classification is afforded by the distinction between tissue-cells (histocytes) and germinal cells, actual or potential (archaeocytes), amongst the constituent cells of the animal body. In this way we may distinguish, first, *vegetative* reproduction, the result of discontinuous growth of the tissues and cell-layers of the body as a whole, leading to (1) *fission*, (2) *autotomy*, or (3) *vegetative budding*; secondly, *germinal* reproduction, the result of the reproductive activity of the archaeocytes or germinal tissue. In germinal reproduction the proliferating cells may be *undifferentiated*, so-called primitive germ-cells, or they may be *differentiated* as sexual cells, male or female, *i.e.* spermatozoa and ova. If the germ-cells are *undifferentiated*, the offspring may arise from many cells or from a single cell; the first type is (4) *germinal budding*, the second is (5) *sporogony*. If the germ-cells are *differentiated*, the offspring arises by *syngamy* or sexual union of the ordinary type between an ovum and spermatozoon, so-called fertilization of the ovum, or by *parthenogenesis*, *i.e.* development of an ovum without fertilization. The only one of these possible modes of reproduction not known to occur in Hydromedusae is parthenogenesis.

(1) True *fission* or longitudinal division of an individual into two equal and similar daughter-individuals is not common but occurs in *Gastroblasta*, where it has been described in detail by Arnold Lang [**30**].

(2) *Autotomy*, sometimes termed transverse fission, is the name given to a process of unequal fission in which a portion of the body separates off with subsequent regeneration. In *Tubularia* by a process of decapitation the hydranths may separate off and give rise to a separate individual, while the remainder of the body grows a new hydranth. Similarly in *Schizocladium* portions of the hydrocaulus are cut off to form so-called "spores," which grow into new individuals (see Allman [**1**]).

(3) *Vegetative budding* is almost universal in the Hydromedusae. By budding is understood the formation of a new individual from a fresh growth of undifferentiated material. It is convenient to distinguish buds that give rise to polyps from those that form medusae.

(*a*) *The Polyp.*—The buds that form polyps are very simple in mode of formation. Four stages may be distinguished; the first is a simple outgrowth of both layers, ectoderm and endoderm, containing a prolongation of the coelenteric cavity; in the second stage the tentacles grow out as secondary diverticula from the side of the first outgrowth; in the third stage the mouth is formed as a perforation of the two layers; and, lastly, if the bud is to be separated, it becomes nipped off from the parent polyp and begins a free existence.

(*b*) *The Medusae.*—Two types of budding must be distinguished—the direct, so-called palingenetic type, and the *indirect*, so-called coenogenetic type.

The direct type of budding is rare, but is seen in *Cunina* and *Millepora*. In *Cunina* there arises, first, a simple outgrowth of both layers, as in a polyp-bud (fig. 43, A); in this the mouth is formed distally as a perforation (B); next the sides of the tube so formed bulge out laterally near the attachment to form the umbrella, while the distal undilated portion of the tube represents the manubrium (C); the umbrella now grows out into a number of lobes or lappets, and the tentacles and tentaculocysts grow out, the former in a notch between two lappets, the latter on the apex of each lappet (D, E); finally, the velum arises as a growth of the ectoderm alone, the whole bud shapes itself, so to speak, and the little medusa is separated off by rupture of the thin stalk connecting it with the parent (F). The direct method of medusa-budding only differs from the polyp-bud by its greater complexity of parts and organs.

The indirect mode of budding (figs. 44, 45) is the commonest method by which medusa-buds are formed. It is marked by the formation in the bud of a characteristic structure termed the *entocodon* (*Knospenkern, Glockenkern*).

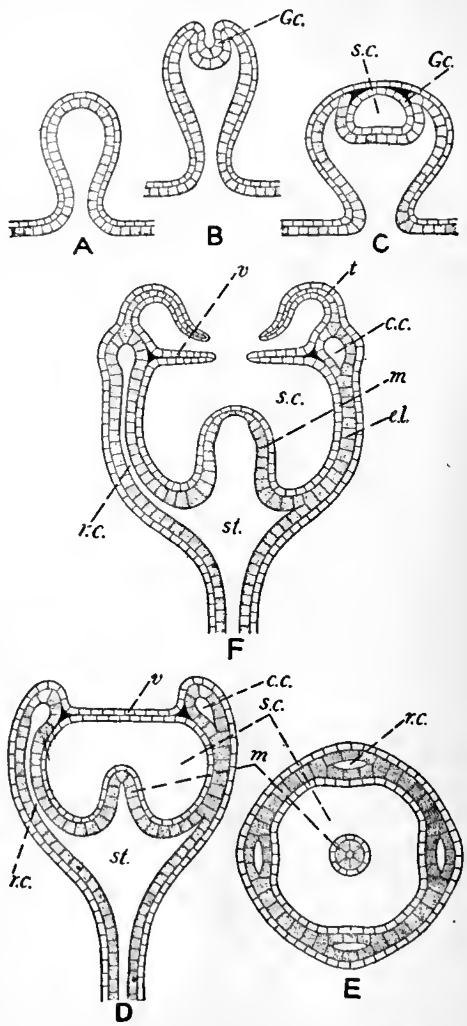

FIG. 44.—Diagrams of Medusa budding with the formation of an entocodon. The endoderm is shaded, the ectoderm left clear.

		e.l,	Endoderm lamella.
Gc,	Entocodon.	*m*,	Manubrium.
s.c,	Cavity of entocodon, forming the future	*v*,	Velum.
		t,	Tentacle.

The first stage is a simple hollow outgrowth of both body-layers (fig. 44, A); at the tip of this is formed a thickening of the ectoderm, arising primitively as a hollow ingrowth (fig. 44, B), but more usually as a solid mass of ectoderm-cells (fig. 45, A). The ectodermal ingrowth is the entocodon (*Gc.*); it bulges into, and pushes down, the endoderm at the apex of the bud, and if solid it soon acquires a cavity (fig. 44, C, *s.c.*). The cavity of the entocodon increases continually in size, while the endoderm pushes up at the sides of it to form a cup with hollow walls, enclosing but not quite surrounding the entocodon, which remains in contact at its outer side with the ectoderm covering the bud (fig. 44, D, *v*). The next changes that take place are chiefly in the endoderm-cup (fig. 44, D, E); the cavity between the two walls of the cup becomes reduced by concrescence to form the radial canals (*r.c.*), ring-canal (*c.c.*), and endoderm-lamella (*e.l.*, fig. 44, E), and at the same time the base of the cup is thrust upwards to form the manubrium (*m*), converting the cavity of the entocodon into a

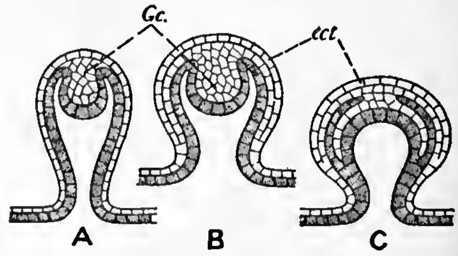

FIG. 45.—Modifications of the method of budding shown in fig. 44, with solid Entocodon (*Gc.*) and formation of an ectotheca (*ect.*).

space which is crescentic or horse-shoe-like in section. Next tentacles (*t*, fig. 44, F) grow out from the ring-canal, and the double plate of ectoderm on the distal side of the entocodon becomes perforated, leaving a circular rim composed of two layers of ectoderm, the velum (*v*) of the medusa. Finally, a mouth is formed by breaking through at the apex of the manubrium, and the now fully-formed medusa becomes separated by rupture of the stalk of the bud and swims away.

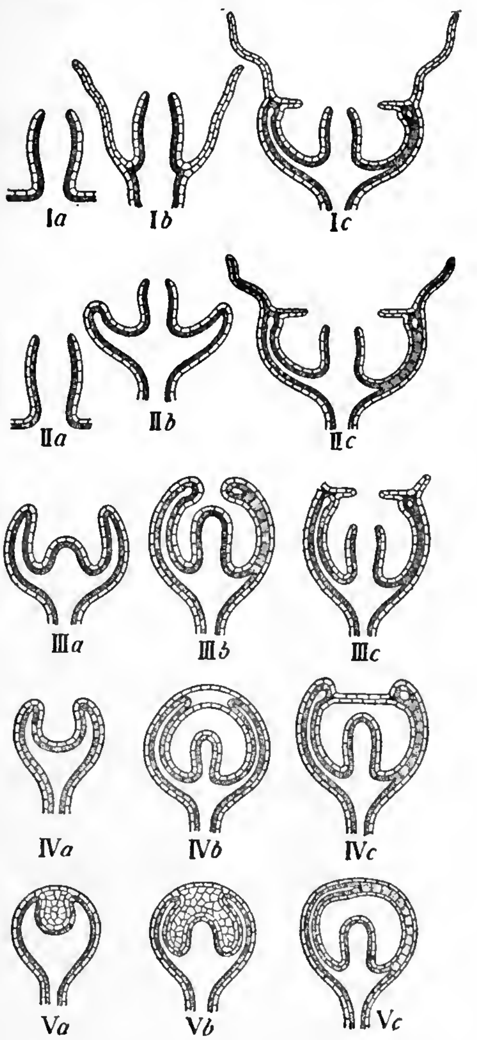

FIG. 46.—Diagrams to show the significance of the Entocodon in Medusa-buds. (Modified from a diagram given by A. Weismann.)

I, Ideally primitive method of budding, in which the mouth is formed first (I*a*), next the tentacles (I*b*), and lastly the umbrella.

II, Method of *Cunina*; (*a*) the mouth arises, next the umbrella (*b*), and lastly the tentacles (*c*).

III, Hypothetical transition from II to the indirect method with an entocodon; the formation of the manubrium is retarded, that of the umbrella hastened (III*a*, *b*).

IV, *a*, *b*, *c*, budding with an entocodon (cf. fig. 44).

V, Budding with a solid entocodon (cf. fig. 45).

If the bud, however, is destined to give rise not to a free medusa, but to a gonophore, the development is similar but becomes arrested at various points, according to the degree to which the gonophore is degenerate. The entocodon is usually formed, proving the medusoid nature of the bud, but in sporosacs the entocodon may be rudimentary or absent altogether. The process of budding as above described may be varied or complicated in various ways; thus a secondary, amnion-like, ectodermal covering or ectotheca (fig. 45, C, *ect.*) may be formed over all, as in *Garveia*, &c.; or the entocodon may remain solid and without cavity until after the formation of the manubrium, or may never acquire a cavity at all, as described above for the gonophores.

Phylogenetic Significance of the Entocodon.—It is seen from the foregoing account of medusa-budding that the entocodon is a very important constituent of the bud, furnishing some of the most essential portions of the medusa; its cavity becomes the sub-umbral cavity, and its lining furnishes the ectodermal epithelium of the manubrium and of the sub-umbral cavity as far as the edge of the velum. Hence the entocodon represents a precocious formation of the sub-umbral surface, equivalent to the peristome of the polyp, differentiated in the bud prior to other portions of the organism which must be regarded as antecedent to it in phylogeny.

If the three principal organ-systems of the medusa, namely mouth, tentacles and umbrella, be considered in the light of phylogeny, it is evident that the manubrium bearing the mouth must be the oldest, as representing a common property of all the Coelentera, even of the gastrula embryo of all Enterozoa. Next in order come the tentacles, common to all Cnidaria. The special property of the medusa is the umbrella, distinguishing the medusa at once from other morphological types among the Coelentera. If, therefore, the formation of these three systems of organs took place according to a strictly phylogenetic sequence, we should expect them to appear in the order set forth above (fig. 46, I*a*, *b*, *c*). The nearest approach to the phylogenetic sequence is seen in the budding of *Cunina*, where the manubrium and mouth appear first, but the umbrella is formed before the tentacles (fig. 46, II*a*, *b*, *c*). In the indirect or coenogenetic method of budding, the first two members of the sequence exhibited by *Cunina* change places, and the umbrella is formed first, the manubrium next, and then the tentacles; the actual mouth-perforation being delayed to the very last (fig. 46, IV*a*, *b*, *c*). Hence the budding of medusae exemplifies very clearly a common phenomenon in development, a phylogenetic series of events completely dislocated in the ontogenetic time-sequence.

The entocodon is to be regarded, therefore, not as primarily an ingrowth of ectoderm, but rather as an upgrowth of both body-layers, in the form of a circular rim (IV*a*), representing the umbrellar margin; it is comparable to the bulging that forms the umbrella in the direct method of budding, but takes place before a manubrium is formed, and is greatly reduced in size, so as to become a little pit. By a simple modification, the open pit becomes a solid ectodermal ingrowth, just as in Teleostean fishes the hollow medullary tube, or the auditory pit of other vertebrate embryos, is formed at first as a solid cord of cells, which acquires a cavity secondarily. Moreover, the entocodon, however developed, gives rise at first to a closed cavity, representing a closing over of the umbrella, temporary in the bud destined to be a free medusa, but usually permanent in the sessile gonophore. As has been shown above, the closing up of the sub-umbral cavity is one of the earliest degenerative changes in the evolution of the gonophore, and we may regard it as the umbrellar fold taking on a protective function, either temporarily for the bud or permanently for the gonophore.

To sum up, the entocodon is a precocious formation of the umbrella, closing over to protect the organs in the umbrellar cavity. The possession of an entocodon proves the medusa-nature of the bud, and can only be explained on the theory that gonophores are degenerate medusae, and is inexplicable on the opposed view that medusae are derived from gonophores secondarily set free. In the sporosac, however, the medusa-individual has become so degenerate that even the documentary proof, so to speak, of its medusoid nature may have been destroyed, and only circumstantial evidence of its nature can be produced.

4. *Germinal Budding.*—This method of budding is commonly described as budding from a single body-layer, instead of from both layers. The layer that produces the bud is invariably the ectoderm, *i.e.* the layer in which, in Hydromedusae, the generative cells are lodged; and in some cases the buds are produced in the exact spot in which later the gonads appear. From these facts, and from those of the sporogony, to be described below, we may regard budding to this type as taking place from the germinal epithelium rather than from ordinary ectoderm.

(*a*) *The Polyp.*—Budding from the ectoderm alone has been described by A. Lang [29] in *Hydra* and other polyps. The tissues of the bud become differentiated into ectoderm and endoderm, and the endoderm of the bud becomes secondarily continuous with that of the parent, but no part of the parental endoderm contributes to the building up of the daughter-polyp. Lang regarded this method of budding as universal in polyps, a notion disproved by O. Seeliger [52] who went to the opposite extreme and regarded the type of budding described by Lang as non-existent. In view, however, both of the statements and figures of Lang and of the facts to be described presently for medusae (*Margellium*), it is at least theoretically possible that both germinal and vegetative budding may occur in polyps as well as in medusae.

(*b*) *The Medusa.*—The clearest instance of germinal budding is furnished by *Margellium* (*Rathkea*) *octopunctatum*, one of the *Margelidae*. The budding of this medusa has been worked out in detail by Chun (HYDROZOA, [1]), to whom the reader must be referred for the interesting laws of budding regulating the sequence and order of formation of the buds.

The buds of *Margellium* are produced on the manubrium in each of the four interradii, and they arise from the ectoderm, that is to say, the germinal epithelium, which later gives rise to the gonads. The buds do not appear simultaneously but successively on each of the four sides of the manubrium, thus:

$$\begin{array}{ccc} & 1 & \\ 3 & & 4 \\ & 2 & \end{array}$$

and secondary buds may be produced on the medusa-buds before the latter are set free as medusae. Each bud arises as a thickening of the epithelium, which first forms two or three layers (fig. 47, A), and becomes separated into a superficial layer, future ectoderm, surrounding a central mass, future endoderm (fig. 47, B). The ectodermal epithelium on the distal side of the bud becomes thickened, grows inwards, and forms a typical entocodon (fig. 37, D, E, F). The remaining development of the bud is just as described above for the indirect method of medusa-budding (fig. 47, G, H). When the bud is nearly complete, the body-wall of the parent immediately below it becomes perforated, placing the coelenteric cavity of the parent in secondary communication with that of the bud (H), doubtless for the better nutrition of the latter.

Especially noteworthy in the germinal budding of *Margellium* is the formation of the entocodon, as in the vegetative budding of the indirect type.

5. *Sporogony.*—This method of reproduction has been described by E. Metchnikoff in *Cunina* and allied genera. In individuals either of the male or female sex, germ-cells which are quite undifferentiated and neutral in character, become amoeboid, and wander into the endoderm. They divide each into two sister-cells, one of which—the spore—becomes enveloped by the other. The spore-cell multiplies by division, while the enveloping cell is nutrient and protective. The spore cell gives rise to a "spore-larva," which is set free in the coelenteron and grows into a medusa. Whether sporogony occurs also in the polyp or not remains to be proved.

6. *Sexual Reproduction and Embryology.*—The ovum of Hydromedusae is usually one of a large number of oögonia, and grows at the expense of its sister-cells. No regular follicle is formed, but the oöcyte absorbs nutriment from the remaining oögonia. In *Hydra* the oöcyte is a large amoeboid cell, which sends out pseudopodia amongst the oögonia and absorbs nutriment from them. When the oöcyte is full grown, the residual oögonia die off and disintegrate.

The spermatogenesis and maturation and fertilization of the germ-cells present nothing out of the common and need not be described here. These processes have been studied in detail by A. Brauer [2] for *Hydra*.

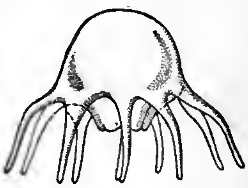
The general course of the development is described in the article Hydrozoa. We may distinguish the following series of stages: (1) ovum; (2) cleavage, leading to formation of a blastula; (3) formation of an inner mass or parenchyma, the future endoderm, by immigration or delamination, leading to the so-called parenchymula-stage; (4) formation of an archenteric cavity, the future coelenteron, by a splitting of the internal parenchyma, and of a blastopore, the future mouth, by perforation at one pole, leading to the gastrula-stage; (5) the outgrowth of tentacles round the mouth (blastopore), leading to the actinula-stage; and (6) the actinula becomes the polyp or medusa in the manner described elsewhere (see articles Hydrozoa, Polyp and Medusa). This is the full, ideal development, which is always contracted or shortened to a greater or less extent. If the embryo is set free as a free-swimming, so-called planula-larva, in the blastula, parenchymula, or gastrula stage, then a free actinula stage is not found; if, on the other hand, a free actinula occurs, then there is no free planula stage.

The cleavage of the ovum follows two types, both seen in *Tubularia* (Brauer [3]). In the first, a cleavage follows each nuclear division; in the second, the nuclei multiply by division a number of times, and then the ovum divides into as many blastomeres as there are nuclei present. The result of cleavage in all cases is a typical blastula, which when set free becomes oval and develops a flagellum to each cell, but when not set free, it remains spherical in form and has no flagella.

The germ-layer formation is always by immigration or delamination, never by invagination. When the blastula is oval and free-swimming the inner mass is formed by unipolar immigration from the hinder pole. When the blastula is spherical and not set free, the germ-layer formation is always multipolar, either by immigration or by delamination, *i.e.* by tangential division of the cells of the blastoderm, as in *Geryonia*, or by a mixture of immigration and delamination, as in *Hydra*, *Tubularia*, &c. The blastopore is formed as a secondary perforation at one spot, in free-swimming forms at the hinder pole. Formation of archenteron and blastopore may, however, be deferred till a later stage (actinula or after).

The actinula stage is usually suppressed or not set free, but it is seen in *Tubularia* (fig. 48), where it is ambulatory, in *Gonionemus* (Trachomedusae), and in *Cunina* (Narcomedusae), where it is parasitic.



Modified from a plate by L. Agassiz, *Contributions to Nat. Hist. U.S.*, iv.

Fig. 48.—Free Actinula of *Tubularia*.

In Leptolinae the embryonic development culminates in a polyp, which is usually formed by fixation of a planula (parenchymula), rarely by fixation of an actinula. The planula may fix itself (1) by one end, and then becomes the hydrocaulus and hydranth, while the hydrorhiza grows out from the base; or (2) partly by one side and then gives rise to the hydrorhiza as well as to the other parts of the polyp; or (3) entirely by its side, and then forms a recumbent hydrorhiza from which a polyp appears to be budded as an upgrowth.

In Trachylinae the development produces always a medusa, and there is no polyp-stage. The medusa arises direct from the actinula-stage and there is no entocodon formed, as in the budding described above.

Life-cycles of the Hydromedusae.—The life-cycle of the Leptolinae consists of an alternation of generations in which non-sexual individuals, polyps, produce by budding sexual individuals, medusae, which give rise by the sexual process to the non-sexual polyps again, so completing the cycle. Hence the alternation is of the type termed metagenesis. The Leptolinae are chiefly forms belonging to the inshore fauna. The Trachylinae, on the other hand, are above all oceanic forms, and have no polyp-stage, and hence there is typically no alternation in their life-cycle. It is commonly assumed that the Trachylinae are forms which have lost the alternation of generations possessed by them ancestrally, through secondary simplification of the life-cycle. Hence the Trachylinae are termed "hypogenetic" medusae to contrast them with the metagenetic Leptolinae. The whole question has, however, been argued at length by W. K. Brooks [4], who adduces strong evidence for a contrary view, that is to say, for regarding the direct type of development seen in Trachylinae as more primitive, and the metagenesis seen in Leptolinae as a secondary complication introduced into the life-cycle by the acquisition of *larval budding*. The polyp is regarded, on this view, as a form phylogenetically older than the medusa, in short, as nothing more than a sessile actinula. In Trachylinae the polyp-stage is passed over, and is represented only by the actinula as a transitory embryonic stage. In Leptolinae the actinula becomes the sessile polyp which has acquired the power of budding and producing individuals either of its own or of a higher rank; it represents a persistent larval stage and remains in a sexually immature condition as a neutral individual, sex being an attribute only of the final stage in the development, namely the medusa. The polyp of the Leptolinae has reached the limit of its individual development and is incapable of becoming itself a medusa, but only produces medusa-buds; hence a true alternation of generations is produced. In Trachylinae also the beginnings of a similar metagenesis can be found. Thus in *Cunina octonaria*, the ovum develops into an actinula which buds daughter-actinulae; all of them, both parent and offspring, develop into medusae, so that there is no alternation of generations, but only larval multiplication. In *Cunina parasitica*, however, the ovum develops into an actinula, which buds actinulae as before, but only the daughter-actinulae develop into medusae, while the original, parent-actinula dies off; here, therefore, larval budding has led to a true alternation of generations. In *Gonionemus* the actinula becomes fixed and polyp-like, and reproduces by budding, so that here also an alternation of generations may occur. In the Leptolinae we must first substitute polyp for actinula, and then a condition is found which can be compared to the case of *Cunina parasitica* or Gonionemus, if we suppose that neither the parent-actinula (*i.e.* founder-polyp) nor its offspring by budding (polyps of the colony) have the power of becoming medusae, but only of producing medusae by budding. For further arguments and illustrations the reader must be referred to Brooks's most interesting memoir. The whole theory is one most intimately connected with the question of the relation between polyp and medusa, to be discussed presently. It will be seen elsewhere, however, that whatever view may be held as to the origin of metagenesis in Hydromedusae, in the case of Scyphomedusae (*q.v.*) no other view is possible than that the alternation of generations is the direct result of larval proliferation.

To complete our survey of life-cycles in the Hydromedusae it is necessary to add a few words about the position of *Hydra* and its allies. If we accept the view that *Hydra* is a true sexual polyp, and that its gonads are not gonophores (*i.e.* medusa-buds) in the extreme of degeneration, then it follows from Brooks's theory that *Hydra* must be descended from an archaic form in which the medusan type of organization had not yet been evolved. *Hydra* must, in short, be a living representative of the ancestor of which the actinula-stage is a transient reminiscence in the development of higher forms. It may be pointed out in this connexion that the fixation of *Hydra* is only temporary, and that the animal is able at all times to detach itself, to move to a new situation, and to fix itself again. There is no difficulty whatever in regarding *Hydra* as bearing the same relation to the actinula-stage of other Hydromedusae that a Rotifer bears to a trochophore-larva or a fish to a tadpole.

The Relation of Polyp and Medusa.—Many views have been put forward as to the morphological relationship between the two types of person in the Hydromedusae. For the most part, polyp and medusa have been regarded as modifications of a common type, a view supported by the existence, among Scyphomedusae (*q.v.*), of sessile polyp-like medusae (*Lucernaria*, &c.). R. Leuckart in 1848 compared medusae in general terms to flattened polyps. G. J. Allman **[1]** put forward a more detailed view, which was as follows. In some polyps the tentacles are webbed at the base, and it was supposed that a medusa was a polyp of this kind set free, the umbrella being a greatly developed web or membrane extending between the tentacles. A very different theory was enunciated by E. Metchnikoff. In some hydroids the founder-polyp, developed from a planula after fixation, throws out numerous outgrowths from the base to form the hydrorhiza; these outgrowths may be radially arranged so as to form by contact or coalescence a flat plate. Mechnikov considered the plate thus formed at the base of the polyp as equivalent to the umbrella, and the body of the polyp as equivalent to the manubrium, of the medusa; on this view the marginal tentacles almost invariably present in medusae are new formations, and the tentacles of the polyp are represented in the medusa by the oral arms which may occur round the mouth, and which sometimes, *e.g.* in *Margelidae*, have the appearance and structure of tentacles. Apart from the weighty arguments which the development furnishes against the theories of Allman and Mechnikov, it may be pointed out that neither hypothesis gives a satisfactory explanation of a structure universally present in medusae of whatever class, namely the endoderm-lamella, discovered by the brothers O. and R. Hertwig. It would be necessary to regard this structure as a secondary extension of the endoderm in the tentacle-web, on Allman's theory, or between the outgrowths of the hydrorhiza, on Mechnikov's hypothesis. The development, on the contrary, shows unequivocally that the endoderm-lamella arises as a local coalescence of the endodermal linings of a primitively extensive gastral space.

The question is one intimately connected with the view taken as to the nature and individuality of polyp, medusa and gonophore respectively. On this point the following theories have been put forward.

1. The theory that the medusa is simply an *organ*, which has become detached and has acquired a certain degree of independence, like the well-known instance of the hectocotyle of the cuttle-fish. On this view, put forward by E. van Beneden and T. H. Huxley, the sporosac is the starting-point of an evolution leading up through the various types of gonophores to the free medusa as the culminating point of a phyletic series. The evidence against this view may be classed under two heads: first, comparative evidence; hydroids very different in their structural characters and widely separate in the systematic classification of these organisms may produce medusae very similar, at least so far as the essential features of medusan organization are concerned; on the other hydroids closely allied, perhaps almost indistinguishable, may produce gonophores in the one case, medusae in the other; for example, *Hydractinia* (gonophores) and *Podocoryne* (medusae), *Tubularia* (gonophores) and *Ectopleura* (medusae), *Coryne* (gonophores) and *Syncoryne* (medusae), and so on. If it is assumed that all these genera bore gonophores ancestrally, then medusa of similar type must have been evolved quite independently in a great number of cases. Secondly, there is the evidence from the development, namely, the presence of the entocodon in the medusa-bud, a structure which, as explained above, can only be accounted for satisfactorily by derivation from a medusan type of organization. Hence it may be concluded that the gonophores are degenerate medusae, and not that the medusae are highly elaborated gonophores, as the organ-theory requires.

2. The theory that the medusa is an independent individual, fully equivalent to the polyp in this respect, is now universally accepted as being supported by all the facts of comparative morphology and development. The question still remains open, however, which of the two types of person may be regarded as the most primitive, the most ancient in the race-history of the Hydromedusae. F. M. Balfour put forward the view that the polyp was the more primitive type, and that the medusa is a special modification of the polyp for reproductive purposes, the result of division of labour in a polyp-colony, whereby special reproductive persons become detached and acquire organs of locomotion for spreading the species. W. K. Brooks, on the other hand, as stated above, regards the medusa as the older type and looks upon both polyp and medusa, in the Hydromedusae, as derived from a free-swimming or floating actinula, the polyp being thus merely a fixed nutritive stage, possessing secondarily acquired powers of multiplication by budding.

The Hertwigs when they discovered the endoderm-lamella showed on morphological grounds that polyp and medusa are independent types, each produced by modification in different directions of a more primitive type represented in development by the actinula-stage. If a polyp, such as *Hydra*, be regarded simply as a sessile actinula, we must certainly consider the polyp to be the older type, and it may be pointed out that in the Anthozoa only polyp-individuals occur. This must not be taken to mean, however, that the medusa is derived from a sessile polyp; it must be regarded as a direct modification of the more ancient free actinula form, without primitively any intervening polyp-stage, such as has been introduced secondarily into the development of the Leptolinae and represents a revival, so to speak, of an ancestral form or larval stage, which has taken on a special role in the economy of the species.

Systematic Review of the Hydromedusae

Order I. **Eleutheroblastea.**—Simple polyps which become sexually mature and which also reproduce non-sexually, but without any medusoid stage in the life-cycle.

The sub-order includes the family *Hydridae*, containing the common fresh-water polyps of the genus *Hydra*. Certain other forms of doubtful affinities have also been referred provisionally to this section.

Hydra.—This genus comprises fresh-water polyps of simple structure. The body bears tentacles, but shows no division into hydrorhiza, hydrocaulus or hydranth; it is temporarily fixed and has no perisarc. The polyp is usually hermaphrodite, developing both ovaries and testes in the same individual. There is no free-swimming planula larva, but the stage corresponding to it is passed over in an enveloping cyst, which is secreted round the embryo by its own ectodermal layer, shortly after the germ-layer formation is complete, *i.e.* in the parenchymula-stage. The envelope is double, consisting of an external chitinous stratified shell, and an internal thin elastic membrane. Protected by the double envelope, the embryo is set free as a so-called "egg," and in Europe it passes the winter in this condition. In the spring the embryo bursts its shell and is set free as a minute actinula which becomes a *Hydra*.

Many species are known, of which three are common in European waters. It has been shown by C. F. Jickeli **(28)** that the species are distinguishable by the characters of their nematocysts. They also show characteristic differences in the egg (Brauer **[2]**). In *Hydra viridis* the polyp is of a green colour and produces a spherical egg with a smooth shell which is dropped into the mud. *H. grisea* is greyish in tint and produces a spherical egg with a spiky shell, which also is dropped into the mud. *H. fusca* (=*H. vulgaris*) is brown in colour, and produces a bun-shaped egg, spiky on the convex surface, and attached to a water-weed or some object by its flattened side. Brauer found a fourth species, similar in appearance to *H. fusca*, but differing from the three other species in being of separate sexes, and in producing a spherical egg with a knobby shell, which is attached like that of *H. fusca*.

The fact already noted that the species of *Hydra* can be distinguished by the characters of their nematocysts is a point of great interest. In each species, two or three kinds of nematocysts occur, some large, some small, and for specific identification the nematocysts must be studied collectively in each species. It is very remarkable that this method of characterizing and diagnozing species has never been extended to the marine hydroids. It is quite possible that the characters of the nematocysts might afford data as useful to the systematist in this group as do the spicules of sponges, for instance. It would be particularly interesting to ascertain how the nematocysts of a polyp are related to those possessed by the medusa budded from it, and it is possible that in this manner obscure questions of relationship might be cleared up.

Protohydra is a marine genus characterized by the absence of tentacles, by a great similarity to *Hydra* in histological structure, and by reproduction by transverse fission. It was found originally in an oyster-farm at Ostend. The sexual reproduction is unknown. For further information see C. Chun (HYDROZOA [1],Pl. I.).

Polypodium hydriforme Ussow is a fresh-water form parasitic on the eggs of the sterlet. A "stolon" of unknown origin produces thirty-two buds, which become as many *Polypodia*; each has twenty-four tentacles and divides by fission repeated twice into four individuals, each with six tentacles. The daughter-individuals grow, form the full number of twenty-four tentacles and divide again. The polyps are free and walk on their tentacles. See Ussow [54].

Tetraplatia volitans Viguier is a remarkable floating marine form. See C. Viguier [56] and Delage and Hérouard (HYDROZOA [2]).

Haleremita Schaudinn. See F. Schaudinn [50] and Delage and Hérouard (HYDROZOA [2]).

In all the above-mentioned genera, with the exception of *Hydra*, the life-cycle is so imperfectly known that their true position cannot be determined in the present state of our knowledge. They may prove eventually to belong to other orders. Hence only the genus *Hydra* can be considered as truly representing the order Eleutheroblastea. The phylogenetic position of this genus has been discussed above.

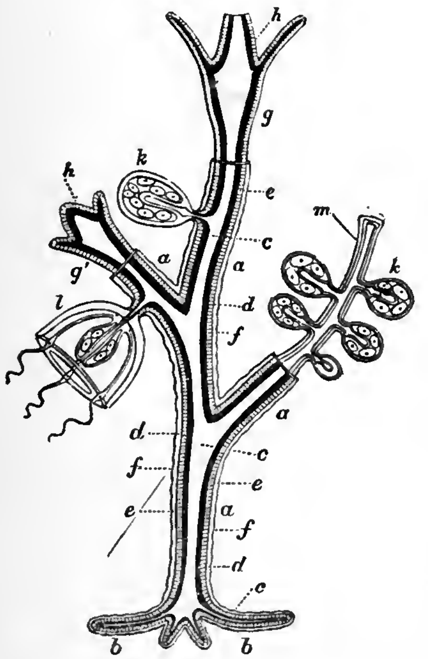


FIG. 49.—Diagram showing possible modifications of persons of a gymnoblastic *Hydromedusa*. (After Allman.)

a, Hydrocaulus (stem).
b, Hydrorhiza (root).
c, Enteric cavity.
d, Endoderm.
e, Ectoderm.
f, Perisarc, (horny case).
g, Hydranth (hydriform person) expanded.
g', Hydranth (hydriform person) contracted.
h, Hypostome, bearing mouth at its extremity.
k, Sporosac springing from the hydrocaulus.
k', Sporosac springing from *m*, a modified hydriform person (blastostyle): the genitalia are seen surrounding the spadix or manubrium.
l, Medusiform person or medusa.
m, Blastostyle.

ORDER II. **Hydroidea seu Leptolinae.**—Hydromedusae with alternation of generations (metagenesis) in which a non-sexual polyp-generation (trophosome) produces by budding a sexual medusa-generation (gonosome). The polyp may be solitary, but more usually produces polyps by budding and forms a polyp-colony. The polyp usually has the body distinctly divisible into hydranth, hydrocaulus and hydrorhiza, and is usually clothed in a perisarc. The medusae may be set free or may remain attached to the polyp-colony and degenerate into a gonophore. When fully developed the medusa is characterized by the sense organs being composed entirely of ectoderm, developed independently of the tentacles, and innervated from the sub-umbral nerve-ring.

The two kinds of persons present in the typical Hydroidea make the classification of the group extremely difficult, for reasons explained above. Hence the systematic arrangement that follows must be considered purely provisional. A natural classification of the Hydroidea has yet to be put forward. Many genera and families are separated by purely artificial characters, mere shelf-and-bottle groupings devised for the convenience of the museum curator and the collector. Thus many subdivisions are diagnosed by setting free medusae in one case, or producing gonophores in another; although it is very obvious, as pointed out above, that a genus producing medusae may be far more closely allied to one producing gonophores than to another producing medusae, or vice versa, and that in some cases the production of medusae or gonophores varies with the season or the sex. Moreover, P. Hallez [22] has recently shown that hydroids hitherto regarded as distinct species are only forms of the same species grown under different conditions.

SUB-ORDER I. HYDROIDEA GYMNOBLASTEA (ANTHOMEDUSAE).—Trophosome without hydrothecae or gonothecae, with monopodial type of budding. Gonosome with free medusae or gonophores; medusae usually with ocelli, never with otocysts. The gymnoblastic polyp usually has a distinct perisarc investing the hydrorhiza and the hydrocaulus, sometimes also the hydranth as far as the bases of the tentacles (*Bimeria*); but in such cases the perisarc forms a closely-fitting investment or cuticule on the hydranth, never a hydrotheca standing off from it, as in the next sub-order. The polyps may be solitary, or form colonies, which may be of the spreading or encrusting type, or arborescent, and then always of monopodial growth and budding. In some cases, any polyp of the colony may bud medusae; in other cases, only certain polyps, the blastostyles, have this power. When blastostyles are present, however, they are never enclosed in special gonothecae as in the next sub-order. In this sub-order the characters of the hydranth are very variable, probably owing to the fact that it is exposed and not protected by a hydrotheca, as in Calyptoblastea.

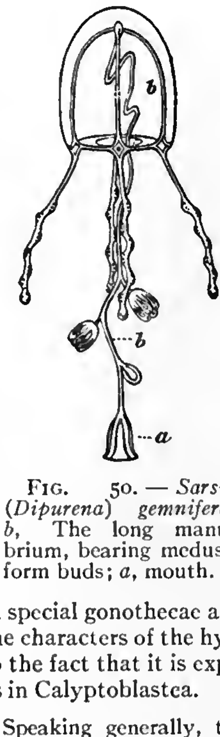

FIG. 50. — *Sarsia (Dipurena) gemmifera.* *b*, The long manubrium, bearing medusiform buds; *a*, mouth.

FIG. 51.—*Sarsia prolifera.* Ocelli are seen at the base of the tentacles, and also (as an exception) groups of medusiform buds.

Speaking generally, three principal types of hydranth can be distinguished, each with subordinate varieties of form.

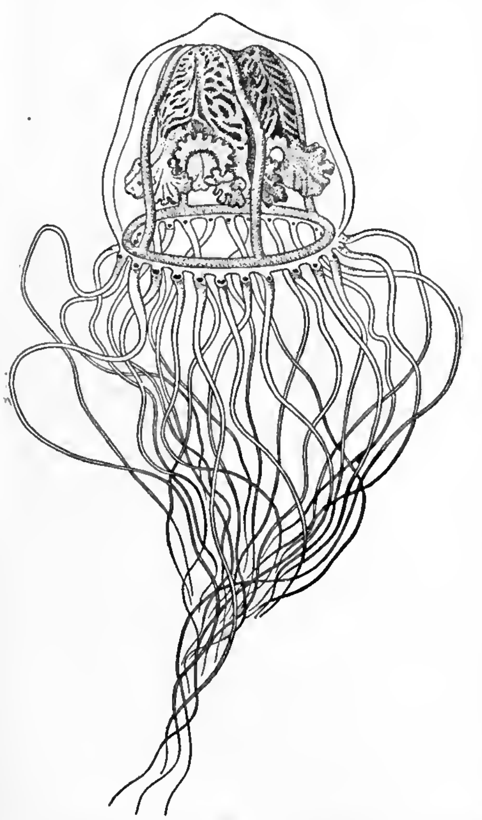
1. Club-shaped hydranths with numerous tentacles, generally scattered irregularly, sometimes with a spiral arrangement, or in whorls ("verticillate").
   (*a*) Tentacles filiform; type of *Clava* (fig. 5), *Cordylophora*, &c.
   (*b*) Tentacles capitate, simple; type of *Coryne* and *Syncoryne*; *Myriothela* is an aberrant form with some of the tentacles modified as "claspers" to hold the ova.
   (*c*) Tentacles capitate, branched, wholly or in part; type of *Cladocoryne*.
   (*d*) Tentacles filiform or capitate, tending to be arranged in definite whorls; type of *Stauridium* (fig. 2), *Cladonema* and *Pennaria*.
2. Hydranth more shortened, daisy-like in form, with two whorls of tentacles, oral and aboral.
   (*a*) Tentacles filiform, simple, radially arranged or scattered irregularly; type of *Tubularia* (fig. 4), *Corymorpha* (fig. 3), *Nemopsis*, *Pelagohydra*, &c.
   (*b*) Tentacles with a bilateral arrangement, branched tentacles in addition to simple filiform ones; type of *Branchiocerianthus*.
3. Hydranth with a single circlet of tentacles.
   (*a*) With filiform tentacles; the commonest type, seen in *Bougainvillea* (fig. 13), *Eudendrium*, &c.
   (*b*) With capitate tentacles; type of *Clavatella*.
4. Hydranth with tentacles reduced below four; type of *Lar* (fig. 11), *Monobrachium*, &c.

The *Anthomedusa* in form is generally deep, bell-shaped. The sense organs are typically ocelli, never otocysts. The gonads are borne on the manubrium, either forming a continuous ring (Codonid type), or four masses or pairs of masses (Oceanid type). The tentacles may be scattered singly round the margin of the umbrella (" monerenematous ") or arranged in tufts (" lophonematous "); in form they may be simple or branched (Cladonemid type); in structure they may be hollow (" coelomerinthous "); or solid (" pycnomerinthous "). When sessile gonophores are produced, they may show all stages of degeneration.

Classification.—Until quite recently the hydroids (Gymnoblastea) and the medusae (Anthomedusae) have been classified separately, since the connexion between them was insufficiently known. Delage and Hérouard (HYDROZOA [2]) were the first to make an heroic attempt to unite the two classifications into one, to which Hickson (HYDROZOA [4]) has made some additions and slight modifications. The classification given here is for the most part that of Delage and Hérouard. It is certain, however, that no such classification can be considered final at present, but must undergo continual revision in the future. With this reservation we may recognize fifteen well-characterized families and others of more doubtful nature. Certain discrepancies must also be noted.

1. *Margelidae* (=medusa-family *Margelidae*+hydroid families *Bougainvillidae*, *Dicorynidae*, *Bimeridae* and *Eudendridae*). Trophosome arborescent, with hydranths of *Bougainvillea*-type; gonosome free medusae or gonophores, the medusae with solid tentacles in tufts (lophonematous). Common genera are the hydroid *Bougainvillea* (figs. 12, 13), and the medusae *Hippocrene* (budded from *Bougainvillea*), *Margelis*, *Rathkea* (fig. 24), and *Margellium*. Other hydroids are *Garveia*, *Bimeria*, *Eudendrium* and *Heterocordyle*, with gonophores, and *Dicoryne* with peculiar sporosacs.

2. *Podocorynidae*(=medusa-families *Thamnostomidae* and *Cytaeidae* +hydroid families *Podocorynidae* and *Hydractiniidae*). Trophosome encrusting with hydranths of *Bougainvillea*-type, polyps differentiated into blastostyles, gastrozoids and dactylozoids; gonosome free medusae or gonophores. The typical genus is the well-known hydroid *Podocoryne*, budding the medusa known as *Dysmorphosa*; *Thamnostylus*, *Cytaeis*, &c., are other medusae with unknown hydroids. *Hydractinia* (figs. 9, 10) is a familiar hydroid genus, bearing gonophores.



After Haeckel, *System der Medusen*, by permission of Gustav Fischer.

FIG. 52.—*Tiara pileata*, L. Agassiz.

3. *Cladonemidae.*—Trophosome, polyps with two whorls of tentacles, the lower filiform, the upper capitate; gonosome, free medusae, with tentacles solid and branched. The type-genus *Cladonema* (fig. 20) is a common British form.

4. *Clavatellidae.*—Trophosome, polyps with a single whorl of capitate tentacles; gonosome, free medusae, with tentacles branched, solid. *Clavatella* (fig. 21), with a peculiar ambulatory medusa is a British form.

5. *Pennariidae.*—Trophosome, polyps with an upper circlet of numerous capitate tentacles, and a lower circlet of filiform tentacles. *Pennaria*, with a free medusa known as *Globiceps*, is a common Mediterranean form. *Stauridium* (fig. 2) is a British hydroid.

6. *Tubulariidae.*—Trophosome, polyps with two whorls of tentacles, both filiform. *Tubularia* (fig. 4), a well-known British hydroid, bears gonophores.

7. *Corymorphidae* (including the medusa-family *Hybocodonidae*).—Trophosome solitary polyps, with two whorls of tentacles; gonosome, free medusae or gonophores. *Corymorpha* (fig. 3), a well-known British genus, sets free a medusa known as *Steenstrupia* (fig. 22). Here belong the deep-sea genera *Monocaulus* and *Branchiocerianthus*, including the largest hydroid polyps known, both genera producing sessile gonophores.

8. *Dendroclavidae.*—Trophosome, polyp with filiform tentacles in three or four whorls. *Dendroclava*, a hydroid, produces the medusa known as *Turritopsis*.

9. *Clavidae* (including the medusa-family *Tiaridae* (figs. 27 and 51). Trophosome, polyps with scattered filiform tentacles; gonosome, medusae or gonophores, the medusae with hollow tentacles. *Clava* (fig. 5), a common British hydroid, produces gonophores; so also does *Cordylophora*, a form inhabiting fresh or brackish water. *Turris* produces free medusae. *Amphinema* is a medusan genus of unknown hydroid.

10. *Bythotiaridae.*—Trophosome unknown; gonosome, free medusae, with deep, bell-shaped umbrella, with interradial gonads on the base of the stomach, with branched radial canals, and correspondingly numerous hollow tentacles. *Bythotiara*, *Sibogita*.

11. *Corynidae*(=hydroid families *Corynidae*, *Syncorynidae* and *Cladocorynidae*+medusan family *Sarsiidae*).—Trophosome polyps with capitate tentacles, simple or branched, scattered or verticillate; gonosome, free medusae or gonophores. *Coryne*, a common British hydroid, produces gonophores; *Syncoryne*, indistinguishable from it, produces medusae known as *Sarsia* (fig. 51). *Cladocoryne* is another hydroid genus; *Codonium* and *Dipurena* (fig. 50) are medusan genera.

After Haeckel, *System der Medusen*, by permission of Gustav Fischer.

FIG. 53.—*Pteronema darwinii.* The apex of the stomach is prolonged into a brood pouch containing embryos.

12. *Myriothelidae.*—The genus *Myriothela* is a solitary polyp with scattered capitate tentacles, producing sporosacs.

13. *Hydrolaridae.*—Trophosome (only known in one genus), polyps with two tentacles forming a creeping colony; gonosome, free medusae with four, six or more radial canals, giving off one or more lateral branches which run to the margin of the umbrella, with the stomach produced into four, six or more lobes, upon which the gonads are developed; the mouth with four lips or with a folded margin; the tentacles simple, arranged evenly round the margin of the umbrella. The remarkable hydroid *Lar* (fig. 11) grows upon the tubes of the worm *Sabella* and produces a medusa known as *Willia*. Another medusan genus is *Proboscidactyla*.

14. *Monobrachiidae.*—The genus *Monobrachium* is a colony-forming hydroid which grows upon the shells of bivalve molluscs, each polyp having but a single tentacle. It buds medusae, which, however, are as yet only known in an immature condition (C. Mereschkowsky [41]).

15. *Ceratellidae.*—Trophosome polyps forming branching colonies of which the stem and main branches are thick and composed of a network of anastomosing coenosarcal tubes covered by a common ectoderm and supported by a thick chitinous perisarc; hydranths similar to those of *Coryne*; gonosome, sessile gonophores. *Ceratella*, an exotic genus from the coast of East Africa, New South Wales and Japan. The genera *Dehitella* Gray and *Dendrocoryne* Inaba should perhaps be referred to this family; the last-named is regarded by S. Goto [16] as the type of a distinct family, *Dendrocorynidae*.

Doubtful families, or forms difficult to classify, are: *Pteronemidae*, Medusae of Cladonemid type, with hydroids for the most part unknown. The British genus *Gemmaria*, however, is budded from a hydroid referable to the family *Corynidae*. *Pteronema* (fig. 53).

Nemopsidae, for the floating polyp *Nemopsis*, very similar to *Tubularia* in character; the medusa, on the other hand, is very similar to *Hippocrene* (*Margelidae*). See C. Chun (HYDROZOA[1]).

Pelagohydridae, for the floating polyp *Pelagohydra*, Dendy, from New Zealand. The animal is a solitary polyp bearing a great number of medusa-buds. The body, representing the hydranth of an ordinary hydroid, has the aboral portion modified into a float, from which hangs down a proboscis bearing the mouth. The float is covered with long tentacles and bears the medusa-buds. The proboscis bears at its extremity a circlet of smaller oral tentacles. Thus the affinities of the hydranth are clearly, as Dendy points out, with a form such as *Corymorpha*, which also is not fixed but only rooted in the mud. The medusae, on the other hand, have the tentacles in four tufts of (in the buds) five each, and thus resemble the medusae of the family *Margelidae*. See A. Dendy [12].

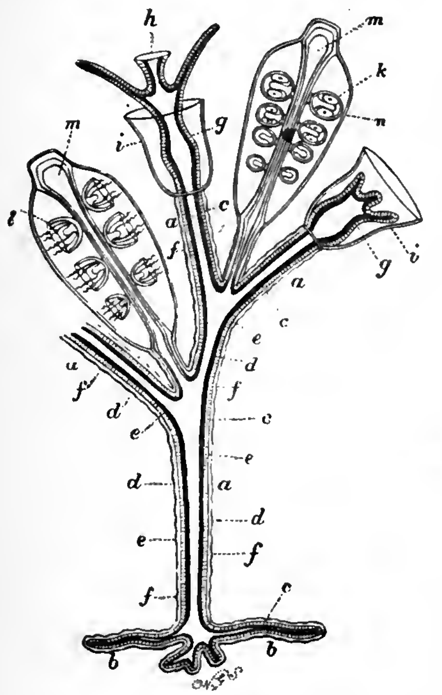


FIG. 54.—Diagram showing possible modifications of the persons of a Calyptoblastic Hydromedusa. Letters *a* to *h* same as in fig. 49. *i*, The horny cup or hydrotheca of the hydriform persons; *l*, medusiform person springing from *m*, a modified hydriform person (blastostyle); *n*, the horny case or gonangium enclosing the blastostyle and its buds. This and the hydrotheca *i* give origin to the name *Calyptoblastea*. (After Allman.)

Perigonimus.—This common British hydroid belongs by its characters to the family *Bougainvillidae*; it produces, however, a medusa of the genus *Tiara* (fig. 52), referable to the family *Clavidae*; a fact sufficient to indicate the tentative character of even the most modern classifications of this order.

SUB-ORDER II. HYDROIDEA CALYPTOBLASTEA (LEPTOMEDUSAE).—Trophosome with polyps always differentiated into nutritive and reproductive individuals (blastostyles) enclosed in hydrothecae and gonothecae respectively; with sympodial type of budding. Gonosome with free medusae or gonophores; the medusae typically with otocysts, sometimes with cordyli or ocelli (figs. 54, 55).

The calyptoblastic polyp of the nutritive type is very uniform in character, its tendency to variation being limited, as it were, by the enclosing hydrotheca. The hydranth almost always has a single circlet of tentacles, like the *Bougainvillea*-type in the preceding sub-order; an exception is the curious genus *Clathrozoon*, in which the hydranth has a single tentacle. The characteristic hydrotheca is formed by the bud at an early stage (fig. 56); when complete it is an open cup, in which the hydranth develops and can be protruded from the opening for the capture of food, or is withdrawn into it for protection. Solitary polyps are unknown in this sub-order; the colony may be creeping or arborescent in form; if the latter, the budding of the polyps, as already stated, is of the sympodial type, and either biserial, forming stems capable of further branching, or uniserial, forming pinnules not capable of further branching. In the biserial type the polyps on the two sides of the stem have primitively an alternating, zigzag arrangement; but, by a process of differential growth, quickened in the 1st, 3rd, 5th, &c., members of the stem, and retarded in the 2nd, 4th, 6th, &c., members, the polyps may assume secondarily positions opposite to one another on the two sides of the stem. Other variations in the mode of growth or budding bring about further differences in the building up of the colony, which are not in all cases properly understood and cannot be described in detail here. The stem may contain a single coenosarcal tube ("monosiphonic") or several united in a common perisarc ("polysiphonic"). An important variation is seen, in the form of the hydrotheca itself, which may come off from the main stem by a stalk, as in *Obelia*, or may be sessile, without a stalk, as in *Sertularia*.

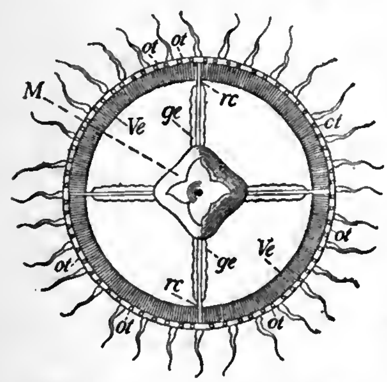

FIG. 55.—View of the Oral Surface of one of the *Leptomedusae* (*Irene pellucida*, Haeckel), to show the numerous tentacles and the otocysts.

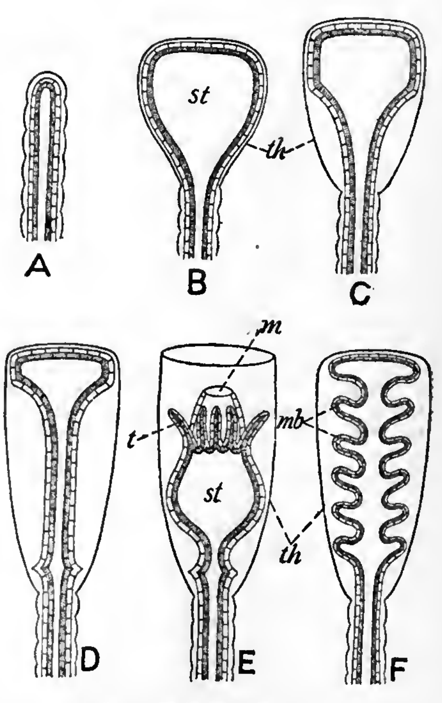
ge, Genital glands. *rc*, The four radiating canals. *M*, Manubrium. *ot*, Otocysts. *Ve*, The velum.

In many Calyptoblastea there occur also reduced defensive polyps or dactylozoids, which in this sub-order have received the special name of *sarcostyles*. Such are the "snake-like zoids" of *Ophiodes* and other genera, and as such are generally interpreted the "macho-polyps" of the *Plumularidae*. These organs are supported by cup-like structures of the perisarc, termed nematophores, regarded as modified hydrothecae supporting the specialized polyp-individuals. They are specially characteristic of the family *Plumularidae*.



After Allman, *Gymnoblastic Hydroids*, by permission of the council of the Ray Society.

FIG. 56.—Diagrams to show the mode of formation of the Hydrotheca and Gonotheca in Calyptoblastic Hydroids. A-D are stages common to both; from D arises the hydrotheca (E) or the gonotheca (F); *th*, theca; *st*, stomach; *t*, tentacles; *m*, mouth; *mb*, medusa-buds.

The medusa-buds, as already stated, are always produced from blastostyles, reduced non-nutritive polyps without mouth or tentacles. An apparent, but not real, exception is *Halecium halecinum*, in which the blastostyle is produced from the side of a nutritive polyp, and both are enclosed in a common theca without a partition between them (Allman [1] p. 50, fig. 24). The gonotheca is formed in its early stage in the same way as the hydrotheca, but the remains of the hydranth persists as an operculum closing the capsule, to be withdrawn when the medusae or genital products are set free (fig. 56).

The blastostyles, gonophores and gonothecae furnish a series of variations which can best be considered as so many stages of evolution.

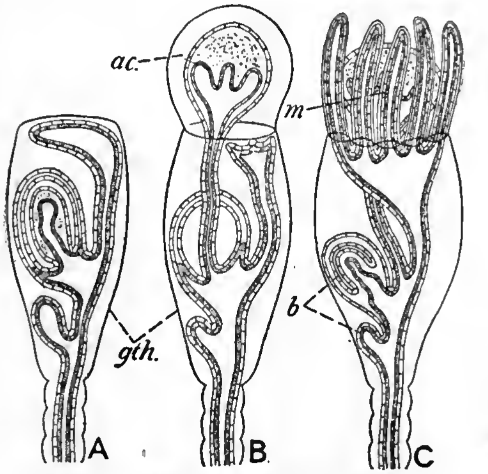
Stage 1, seen in *Obelia*. Numerous medusae are budded successively within the gonotheca and set free; they swim off and mature in the open sea (Allman [1], p. 48, figs. 18, 19).

Stage 2, seen in *Gonothyraea*. Medusae, so-called "meconidia," are budded but not liberated; each in turn, when it reaches sexual maturity, is protruded from the gonotheca by elongation of the stalk, and sets free the embryos, after which it withers and is replaced by another (Allman [1], p. 57, fig. 28).

Stage 3, seen in *Sertularia*.—The gonophores are reduced in varying degree, it may be to sporosacs; they are budded successively from the blastostyle, and each in turn, when ripe, protrudes the spadix through the gonotheca (fig. 57, A, B). The spadix forms a gelatinous cyst, the so-called acrocyst (*ac*), external to the gonotheca (*gth*), enclosing and protecting the embryos. Then the spadix withers, leaving the embryos in the acrocyst, which may be further protected by a so-called marsupium, a structure formed by tentacle-like processes growing out from the blastostyle to enclose the acrocyst, each such process being covered by perisarc like a glove-finger secreted by it (fig. 57, C). (Allman [1], pp. 50, 51, figs., 21-24; Weismann [58], p. 170, pl. ix., figs. 7, 8.)

Stage 4, seen in *Plumularidae*.—The generative elements are produced in structures termed corbulae, formed by reduction and modification of branches of the colony. Each corbula contains a central row of blastostyles enclosed and protected by lateral rows of branches representing stunted buds (Allman [**1**], p. 60, fig. 30).

The *Leptomedusa* in form is generally shallow, more or less saucer-like, with velum less developed than in Anthomedusae (fig. 55). The characteristic sense-organs are ectodermal otocysts, absent, however, in some genera, in which case cordyli may replace them. When otocysts are present, they are at least eight in number, situated adradially, but are often very numerous. The cordyli are scattered on the ring-canal. Ocelli, if present, are borne on the tentacle-bulbs. The tentacles are usually hollow, rarely solid (*Obelia*). In number they are rarely less than four, but in *Dissonema* there are only two. Primitively there are four perradial tentacles, to which may be added four interradial, or they may become very numerous and are then scattered evenly round the margin, never arranged in tufts or clusters. In addition to tentacles, there may be marginal cirri (*Laodice*) with a solid endodermal axis, spirally coiled, very contractile, and bearing a terminal battery of nematocysts. The gonads are developed typically beneath the radial canals or below the stomach or its pouches, often stretching as long bands on to the base of the manubrium. In *Octorchidae* (fig. 58) each such band is interrupted, forming one mass at the base of the manubrium and another below the radial canal in each radius, in all eight separate gonad-masses, as the name implies. In some Leptomedusae excretory "marginal tubercles" are developed on the ring-canal.



After Allman, *Gymnoblastic Hydroids*, by permission of the council of the Ray Society.

FIG. 57.—Diagrams to show the mode of formation of an Acrocyst and a Marsupium. In A two medusa-buds are seen within the gonotheca (*gth*), the upper more advanced than the lower one. In B the spadix of the upper bud has protruded itself through the top of the gonotheca and the acrocyst (*ac*) is secreted round it. In C the marsupium (*m*) is formed as finger-like process from the summit of the blastostyle, enclosing the acrocyst; *b*, medusa-buds on the blastostyle.

Classification.—As in the Gymnoblastea, the difficulty of uniting the hydroid and medusan systems into one scheme of classification is very great in the present state of our knowledge. In a great many Leptomedusae the hydroid stage is as yet unknown, and it is by no means certain even that they possess one. It is quite possible that some of these medusae will be found to be truly hypogenetic, that is to say, with a life-cycle secondarily simplified by suppression of metagenesis. At present, ten recent and one extinct family of Calyptoblastea (Leptomedusae) may be recognized provisionally:

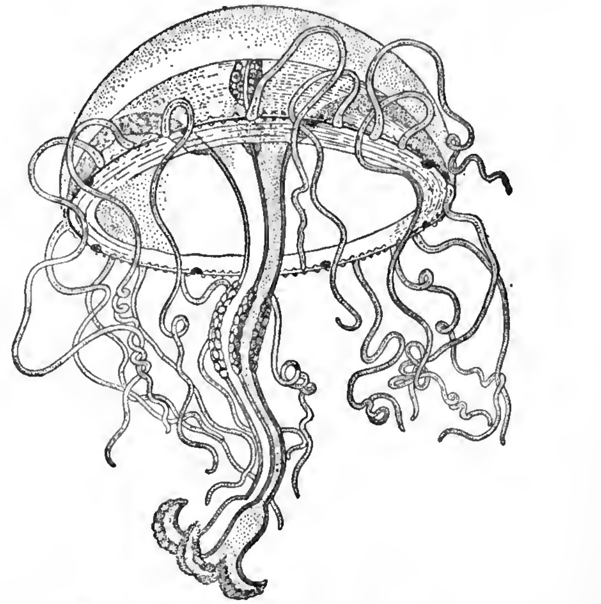
1. *Eucopidae* (figs. 55, 59).—Trophosome with stalked hydrothecae; gonosome, free medusae with otocysts and four, rarely six or eight, unbranched radial canals. Two of the commonest British hydroids belong to this family, *Obelia* and *Clytia*. *Obelia* forms numerous polyserial stems of the characteristic zigzag pattern growing up from a creeping basal stolon, and buds the medusa of the same name. In *Clytia* the polyps arise singly from the stolon, and the medusa is known as *Phialidium* (fig. 59).

2. *Aequoridae*.—Trophosome only known in one genus (*Polycanna*), and similar to the preceding; gonosome, free medusae with otocysts and with at least eight radial canals, often a hundred or more, simple or branched. *Aequorea* is a common medusa.

3. *Thaumantidae*.—Trophosome only known in one genus (*Thaumantias*), similar to that of the *Eucopidae*; gonosome, free medusae with otocysts inconspicuous or absent, with usually four, sometimes eight, rarely more than eight, radial canals, simple and unbranched, along which the gonads are developed, with numerous tentacles bearing ocelli and with marginal sense-clubs. *Laodice* and *Thaumantias* are representative genera.

4. *Berenicidae*.—Trophosome unknown; gonosome, free medusae, with four or six radial canals, bearing the gonads, with numerous tentacles, between which occur sense-clubs, without otocysts. *Berenice*, *Staurodiscus*, &c.

5. *Polyorchidae*.—Trophosome unknown; gonosome, free medusae of deep form, with radial canals branched in a feathery manner, and bearing gonads on the main canal, but not on the branches, with numerous hollow tentacles bearing ocelli, and without otocysts. *Polyorchis*, *Spirocodon*.



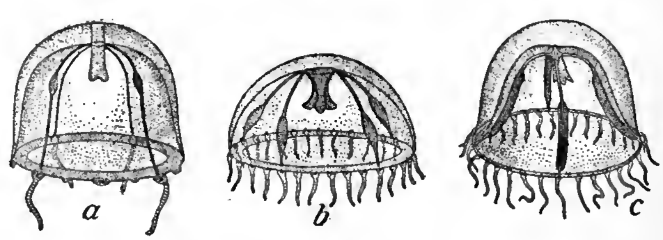
After Haeckel, *System der Medusen*, by permission of Gustav Fischer.

FIG. 58.—*Octorchandra canariensis*, from life, magnified 4 diameters.

6. *Campanularidae*.—Trophosome as in *Eucopidae*; gonosome, sessile gonophores. Many common or well-known genera belong here, such as *Halecium*, *Campanularia*, *Gonothyraea*, &c.

7. *Lafoëidae*.—Trophosome as in the preceding; gonosome, free medusae or gonophores, the medusae with large open otocysts. The hydroid genus *Lafoëa* is remarkable for producing gonothecae on the hydrorhiza, each containing a blastostyle which bears a single gonophore; this portion of the colony was formerly regarded as an independent parasitic hydroid, and was named *Coppinia*. Medusan genera are *Mitrocoma*, *Halopsis*, *Tiaropsis* (fig. 29, &c.).

(So far as the characters of the trophosome are concerned, the seven preceding families are scarcely distinguishable, and they form a section apart, contrasting sharply with the families next to be mentioned, in none of which are free medusae liberated from the colony, so that only the characters of the trophosome need be considered.)



After E. T. Browne, *Proc. Zool. Soc. of London*, 1896.

FIG. 59.—Three stages in the development of *Phialidium temporarium*. *a*, The youngest stage, is magnified 22 diameters; *b*, older, is magnified 8 diameters; *c*, the adult medusa, is magnified 6 diameters.

8. *Sertularidae*.—Hydrothecae sessile, biserial, alternating or opposite on the stem. *Sertularia* and *Sertularella* are two very common genera of this family.

9. *Plumularidae*.—Hydrothecae sessile, biserial on the main stem, uniserial on the lateral branches or pinnules, which give the colony its characteristic feathery form; with nematophores. A very abundant and prolific family; well-known British genera are *Plumularia*, *Antennularia* and *Aglaophenia*.

10. *Hydroceratinidae*.—This family contains the single Australian species *Clathrozoon wilsoni* Spencer, in which a massive hydrorhiza

bears sessile hydrothecae, containing hydranths each with a single tentacle, and numerous nematophores. See W. B. Spencer [53].

11. *Dendrograptidae*, containing fossil (Silurian) genera, such as *Dendrograptus* and *Thamnograptus*, of doubtful affinities.

Order III. **Hydrocorallinae.**—Metagenetic colony-forming Hydromedusae, in which the polyp-colony forms a massive, calcareous *corallum* into which the polyps can be retracted; polyp-individuals always of two kinds, gastrozoids and dactylozoids; gonosome either free medusae or sessile gonophores. The trophosome consists of a mass of coenosarcal tubes anastomosing in all planes. The interspaces between the tubes are filled up by a solid mass of lime, consisting chiefly of calcium carbonate, which replaces the chitinous perisarc of ordinary hydroids and forms a stony corallum or *coenosteum* (fig. 60). The surface of the coenosteum is covered by a layer of common ectoderm, containing large nematocysts, and is perforated by pores of two kinds, gastropores and dactylopores, giving exit to gastrozoids and dactylozoids respectively, which are lodged in vertical pore-canals of wider calibre than the coenosarcal canals of the general network. The coenosteum increases in size by new growth at the surface; and in the deeper, older portions of massive forms the tissues die off after a certain time, only the superficial region retaining its vitality down to a certain depth. The living tissues at the surface are cut off from the underlying dead portions by horizontal partitions termed *tabulae*, which are formed successively as the coenosteum increases in age and size. If the coenosteum of *Millepora* be broken across, each pore-canal (perhaps better termed a polyp-canal) is seen to be interrupted by a series of transverse partitions, representing successive periods of growth with separation from the underlying dead portions.

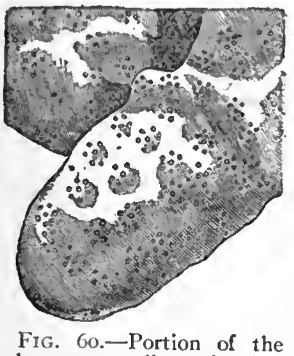


Fig. 60.—Portion of the calcareous corallum of *Millepora nodosa*, showing the cyclical arrangement of the pores occupied by the "persons" or hydranths. Twice the natural size. (From Moseley.)

Besides the wider vertical pore-canals and the narrower, irregular coenosarcal canals, the coenosteum may contain, in its superficial portion, chambers or *ampullae*, in which the reproductive zoids (medusae or gonophores) are budded from the coenosarc.

Fig. 61.—Enlarged view of the surface of a living *Millepora*, showing five dactylozooids surrounding a central gastrozooid. (From Moseley.)

The gastropores and dactylopores are arranged in various ways at the surface, a common pattern being the formation of a cyclosystem (fig. 60), in which a central gastrozoid is surrounded by a ring of dactylozoids (fig. 61). In such a system the dactylopores may be confluent with the gastropore, so that the entire cyclosystem presents itself as a single aperture subdivided by radiating partitions, thus having a superficial resemblance to a madreporarian coral with its radiating septa (figs. 62 and 63).

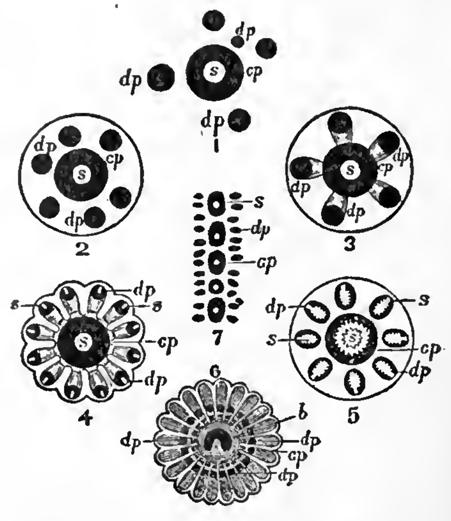

Fig. 62.—Diagrams illustrating the successive stages in the development of the cyclosystems of the *Stylasteridae*. (After Moseley.)

1, *Sporadopora dichotoma*.
2, 3, *Allopora nobilis*.
4, *Allopora profunda*.
5, *Allopora miniacea*.
6, *Astylus subviridis*.
7, *Distichopora coccinea*.

s, Style.
dp, Dactylopore.
gp, Gastropore.
b, In fig. 6, inner horseshoe-shaped mouth of gastropore.

The gastrozoids usually bear short capitate tentacles, four, six or twelve in number; but in *Astylus* (fig. 63) they have no tentacles. The dactylozoids have no mouth; in *Milleporidae* they have short capitate tentacles, but lack tentacles in *Stylasteridae*.

The gonosome consists of free medusae in *Milleporidae*, which are budded from the apex of a dactylozoid in *Millepora murrayi*, but in other species from the coenosarcal canals. The medusae are produced by direct budding, without an entocodon in the bud. They are liberated in a mature condition, and probably live but a short time, merely sufficient to spread the species. The manubrium bearing the gonads is mouthless, and the umbrella is without tentacles, sense-organs, velum or radial canals. In the *Stylasteridae* sessile gonophores are formed, always by budding from the coenosarc. In *Distichopora* the gonophores have radial canals, but in other genera they are sporosacs with no trace of medusoid structure.

Classification.—Two families are known:—

1. *Milleporidae.*—Coenosteum massive, irregular in form; pores scattered irregularly or in cyclosystems, without styles, with transverse tabulae; free medusae. A single genus, *Millepora* (figs. 60, 61).

2. *Stylasteridae.*—Coenosteum arborescent, sometimes fanlike, with pores only on one face, or on the lateral margins of the branches; gastropores with tabulae only in two genera, but with (except in *Astylus*) a *style*, *i.e.* a conical, thorn-like projection from the base of the pore, sometimes found also in dactylopores; sessile gonophores. *Sporadopora* has the pores scattered irregularly. *Distichopora* has the pores arranged in rows. *Stylaster* has cyclosystems. In *Allopora* the cyclostems resemble the calyces of Anthozoan corals. In *Cryptohelia* the cyclosystem is covered by a cap or operculum. In *Astylus* (fig. 63) styles are absent.

Fig. 63.—Portion of the corallum of *Astylus subviridis* (one of the *Stylasteridae*), showing cyclosystems placed at intervals on the branches, each with a central gastropore and zone of slit-like dactylopores. (After Moseley.)

Affinities of the Hydrocorallinae.—There can be no doubt that the forms comprised in this order bear a close relationship to the Hydroidea, especially the sub-order Gymnoblastea, with which they should perhaps be classed in a natural classification. A hydrocoralline may be regarded as a form of hydroid colony in which the coenosarc forms a felt-work ramifying in all planes, and in which the chitinous perisarc is replaced by a massive calcareous skeleton. So far as the trophosome is concerned, the step from an encrusting hydroid such as *Hydractinia* to the hydrocoralline *Millepora* is not great.

Hickson considers that the families *Milleporidae* and *Stylasteridae* should stand quite apart from one another and should not be united in one order. The nearest approach to the *Stylasteridae* is perhaps to be found in *Ceratella*, with its arborescent trophosome formed of anastomosing coenosarcal tubes supported by a thick perisarc and covered by a common ectoderm. *Ceratella* stands in much the same relation to the *Stylasteridae* that *Hydractinia* does to the *Milleporidae*, in both cases the chitinous perisarc being replaced by the solid coenosteum to which the hydrocorallines owe the second half of their name.

ORDER IV. **Graptolitoidea** (Rhabdophora, Allman).—This order has been constituted for a peculiar group of palaeozoic fossils, which have been interpreted as the remains of the skeletons of Hydrozoa of an extinct type.

A typical graptolite consists of an axis bearing a series of tooth-like projections, like a saw. Each such projection is regarded as representing a cup or hydrotheca, similar to those borne by a calyptoblastic hydroid, such as *Sertularia*. The supposed hydrothecae may be present on one side of the axis only (monoprionid) or on both sides (diprionid); the first case may be conjectured to be the result of uniserial (helicoid) budding, the second to be produced by biserial (scorpioid) budding. In one division (*Retiolitidae*) the axis is reticulate. In addition to the stems bearing cups, there are found vesicles associated with them, which have been interpreted as gonothecae or as floats, that is to say, air-bladders, acting as hydrostatic organs for a floating polyp-colony.

Since no graptolites are known living, or, indeed, since palaeozoic times, the interpretation of their structure and affinities must of necessity be extremely conjectural, and it is by no means certain that they are Hydrozoa at all. It can only be said that their organization, so far as the state of their preservation permits it to be ascertained, offers closer analogies with the Hydrozoa, especially the Calyptoblastea, than with any other existing group of the animal kingdom.

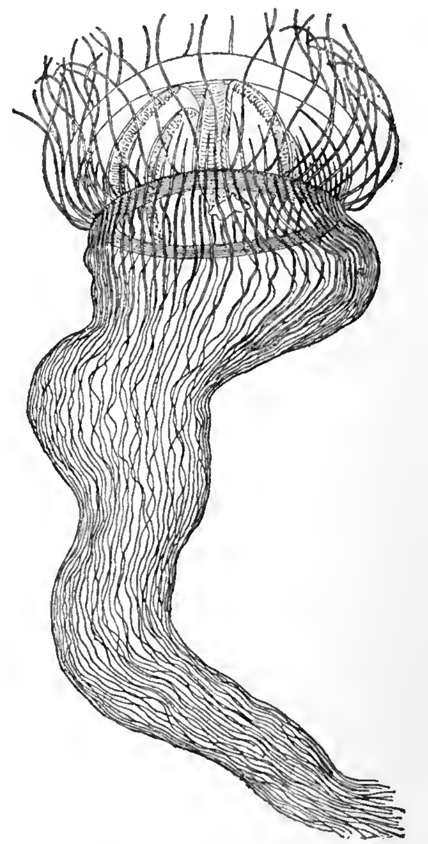
See the treatise of Delage and Hérouard (HYDROZOA, [4]), and the article GRAPTOLITES.

ORDER V. **Trachylinea.**—Hydromedusae without alternation of generations, *i.e.* without a hydroid phase; the medusa develops directly from the actinula larva, which may, however, multiply by budding. Medusae with sense-organs represented by otocysts derived from modified tentacles (tentaculocysts), containing otoliths of endodermal origin, and innervated from the ex-umbral nerve-ring.

This order, containing the typical oceanic medusae, is divided into two sub-orders.

SUB-ORDER 1. TRACHOMEDUSAE.—Tentacles given off from the margin of the umbrella, which is entire, *i.e.* not lobed or indented; tentaculocysts usually enclosed in vesicles; gonads on the radial canals. The medusae of this order are characterized by the tough, rigid consistence of the umbrella, due partly to the dense nature of the mesogloea, partly to the presence of a marginal rim of chondral tissue, consisting of thickened ectoderm containing great numbers of nematocysts, and forming, as it were, a cushion-tyre supporting the edge of the umbrella. Prolongations from the rim of chondral tissue may form clasps or *peronia* supporting the tentacles. The tentacles are primarily four in number, perradial, alternating with four interradial tentaculocysts, but both tentacles and sense-organs may be multiplied and the primary perradii may be six instead of four (fig. 26). The tentacles are always solid, containing an axis of endoderm-cells resembling notochordal tissue or plant-parenchyma, and are but moderately flexible. The sense-organs are tentaculocysts which are usually enclosed in vesicles and may be sunk far below the surface. The gonads are on the radial canals or on the stomach (*Ptychogastridae*), and each gonad may be divided into two by a longitudinal sub-umbral muscle-tract. The radial canals are four, six, eight or more, and in some genera blindly-ending centripetal canals are present (fig. 26). The stomach may be drawn out into the manubrium, forming a proboscis (" Magenstiel ") of considerable length.

The development of the Trachomedusae, so far as it is known, shows an actinula-stage which is either free (larval) or passed over in the egg (foetal) as in *Geryonia*; in no case does there appear to be a free planula-stage. The actinula, when free, may multiply by larval budding, but in all cases both the original actinula and all its descendants become converted into medusae, so that there is no alternation of generations. In *Gonionemus* the actinula becomes attached and polyp-like and reproduces by budding.



After Haeckel, *System der Medusen*, by permission of Gustav Fischer.

FIG. 64.—*Olindias mülleri*, twice natural size.

The Trachomedusae are divided into the following families:

1. *Petasidae* (*Petachnidae*).—Four radial canals, four gonads; stomach not prolonged into the manubrium, which is relatively short; tentaculocysts free. *Petasus* and other genera make up this family, founded by Haeckel, but no other naturalist has ever seen them, and it is probable that they are simply immature forms of other genera.

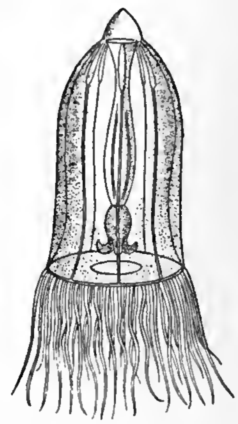
2. *Olindiadae*, with four radial canals and four gonads; manubrium short; ring-canals giving off blind centripetal canals; tentaculocysts enclosed. *Olindias mülleri* (fig. 64) is a common Mediterranean species. Other genera are *Aglauropsis*, *Gossea* and *Gonionemus*; the last named bears adhesive suckers on the tentacles. Some doubt attaches to the position of this family. It has been asserted that the tentaculocysts are entirely ectodermal and that either the family should be placed amongst the Leptomedusae, or should form, together with certain Leptomedusae, an entirely distinct order. In *Gonionemus*, however, the concrement-cells are endodermal.

3. *Trachynemidae*.—Eight radial canals, eight gonads, stomach not prolonged into manubrium; tentaculocysts enclosed. *Rhopalonema*, *Trachynema*, &c.

4. *Ptychogastridae* (*Pectyllidae*).—As in the preceding, but with suckers on the tentacles. *Ptychogastria* Allman (= *Pectyllis*), a deep-sea form.

5. *Aglauridae*.—Eight radial canals, two, four or eight gonads; tentacles numerous; tentaculocysts free; stomach prolonged into manubrium. *Aglaura*, *Aglantha* (fig. 65), &c., with eight gonads; *Stauraglaura* with four; *Persa* with two. *Amphogona*, hermaphrodite, with male and female gonads on alternating radial canals.

6. *Geryonidae*.—Four or six radial canals; gonads band-like; stomach prolonged into a manubrium of great length; tentaculocysts enclosed. *Liriope*, &c., with four radial canals; *Geryonia*, *Carmarina* (fig. 26), &c., with six.



After E. T. Browne, *Proc. Zool. Soc. of London*.

FIG. 65.—*Aglantha rosea* (Forbes), a British medusa, ×5.

7. *Halicreidae*.—Eight very broad radial canals; ex-umbrella often provided with lateral outgrowths; tentacles differing in size, but in a single row. *Halicreas*.

SUB-ORDER 2. NARCOMEDUSAE.—Margin of the umbrella lobed, tentacles arising from the ex-umbrella at some distance from the margin; tentaculocysts exposed, not enclosed in vesicles; gonads on the sub-umbral floor of the stomach or of the gastric pouches.

The Narcomedusae exhibit peculiarities of form and structure which distinguish them at once from all other Hydromedusae. The umbrella is shallow and has the margin supported by a rim of thickened ectoderm, as in the Trachomedusae, but not so strongly developed. The tentacles are not inserted on the margin of the umbrella, but arise high up on the ex-umbral surface, and the umbrella is prolonged into lobes corresponding to the interspaces between the tentacles. The condition of things can be imagined by supposing that in a medusa primitively of normal build, with tentacles at the margin, the umbrella has grown down past the insertion of the tentacles. As a result of this extension of the umbrellar margin, all structures belonging to this region, namely, the ring-canal, the nerve-rings, and the rim of thickened ectoderm, do not run an even course, but are thrown into festoons, caught up under the insertion of each tentacle in such a way that the ring-canal and its accompaniments form in each notch of the umbrellar margin an inverted V, the apex of which corresponds to the insertion of the tentacle; in some cases the limbs of the V may run for some distance parallel to one another, and may be fused into one, giving a figure better compared to an inverted Y. Thus the ectodermal rim runs round the edge of each lobe of the umbrella and then passes upwards towards the base of the tentacle from the re-entering angle between two adjacent lobes, to form with its fellow of the next lobe a tentacle-clasp or *peronium*, *i.e.* a streak of thickened ectoderm supporting the tentacle. Similarly the ring-canal runs round the edge of the lobe as the so-called festoon-canal, and then runs upwards under the peronium to the base of the tentacle as one of a pair of peronial canals, the limbs of the V-like figure already mentioned. The nerve-rings have a similar course. The tentaculocysts are implanted round the margins of the lobes of the umbrella and may be supported by prolongations of the ectodermal rim termed *otoporpae* (*Gehörspangen*). The radial canals are represented by wide gastric pouches, and may be absent, so that the tentacles arise directly from the stomach (*Solmaridae*). The tentacles are always solid, as in Trachomedusae.

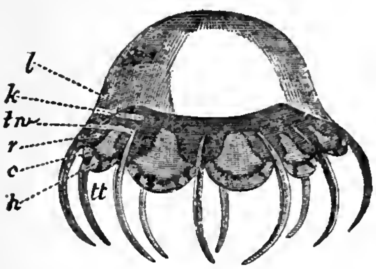


FIG. 66.—*Cunina rhododactyla*, one of the *Narcomedusae*. (After Haeckel.)
c, Circular canal.
h, "Otoporpae" or centripetal process of the marginal cartilaginous ring connected with tentaculocyst.
k, Stomach.
l, Jelly of the disk.
r, Radiating canal (pouch of stomach).
tt, Tentacles.
tw, Tentacle root.

The development of the Narcomedusae is in the main similar to that of the Trachomedusae, but shows some remarkable features. In *Aeginopsis* a planula is formed by multipolar immigration. The two ends of the planula become greatly lengthened and give rise to the two primary tentacles of the actinula, of which the mouth arises from one side of the planula. Hence the principal axis of the future medusa corresponds, not to the longitudinal axis of the planula, but to a transverse axis. This is in some degree parallel to the cases described above, in which a planula gives rise to the hydrorhiza, and buds a polyp laterally.

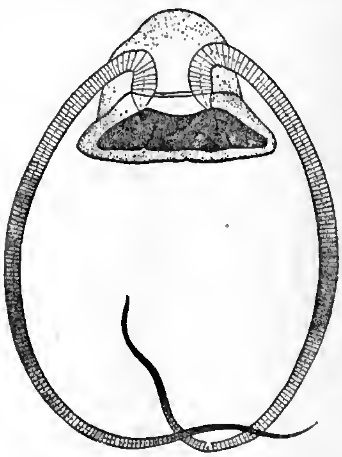
In *Cunina* and allied genera the actinula, formed in the manner described, has a hypostome of great length, quite disproportionate to the size of the body, and is further endowed with the power of producing buds from a stolon arising from the aboral side of the body. In these species the actinula is parasitic upon another medusa; for instance, *Cunoctantha octonaria* upon *Turritopsis*, *C. proboscidea* upon *Liriope* or *Geryonia*. The parasite effects a lodgment in the host either by invading it as a free-swimming planula, or, apparently, in other cases, as a spore-embryo which is captured and swallowed as food by the host. The parasitic actinula is found attached to the proboscis of the medusa; it thrusts its greatly elongated hypostome into the mouth of the medusa and nourishes itself upon the food in the digestive cavity of its host. At the same time it produces buds from an aboral stolon. The buds become medusae by the direct method of budding described above. In some cases the buds do not become detached at once, but the stolon continues to grow and to produce more buds, forming a "bud-spike" (*Knospenähre*), which consists of the axial stolon bearing medusa-buds in all stages of development. In such cases the original parent-actinula does not itself become a medusa, but remains arrested in development and ultimately dies off, so that a true alternation of generations is brought about. It is in these parasitic forms that we meet with the method of reproduction by sporogony described above.

In other Narcomedusae, *e.g. Cunoctantha fowleri* Browne, buds are formed from the sub-umbrella on the under side of the stomach pouches, where later the gonads are developed.

Classification.—Three families of Narcomedusae are recognized (see O. Maas [40]):

1. *Cunanthidae.*—With broad gastric pouches which are simple, *i.e.* undivided, and "pernemal," *i.e.* correspond in position with the tentacles. *Cunina* (fig. 66) with more than eight tentacles; *Cunoctantha* with eight tentacles, four perradial, four interradial.

2. *Aeginidae.*—Radii a multiple of four, with radial gastric pouches bifurcated or subdivided; the tentacles are implanted in the notch between the two subdivisions of each (primary) gastric pouch, hence the (secondary) gastric pouches appear to be "internemal" in position, *i.e.* to alternate in position with the tentacles. *Aegina*, with four tentacles and eight pouches; *Aeginura* (fig. 25), with eight tentacles and sixteen pouches; *Solmundella* (fig. 67), with two tentacles and eight pouches; *Aeginopsis* (fig. 23), with two or four tentacles and sixteen pouches.



After O. Maas, *Craspedoten Medusen der Siboga Expedition*, by permission of E. S. Brill & Co.

FIG. 67.—*Solmundella bitentaculata* (Quoy and Gaimard).

3. *Solmaridae.*—No gastric pouches; the numerous tentacles arise direct from the stomach, into which also the peronial canals open, so that the ring-canal is cut up into separate festoons. *Solmaris*, *Pegantha*, *Polyxenia*, &c. To this family should be referred, probably, the genus *Hydroctena*, described by C. Dawydov [11a] and regarded by him as intermediate between Hydromedusae and Ctenophora. See O. Maas [35].

Appendix to the Trachylinae.

Of doubtful position, but commonly referred to the Trachylinae, are the two genera of fresh-water medusae, *Limnocodium* and *Limnocnida*.

Limnocodium sowerbyi was first discovered in the *Victoria regia* tank in the Botanic Gardens, Regent's Park, London. Since then it has been discovered in other botanic gardens in various parts of Europe, its two most recent appearances being at Lyons (1901) and Munich (1905), occurring always in tanks in which the *Victoria regia* is cultivated, a fact which indicates that tropical South America is its original habitat. In the same tanks a small hydroid, very similar to *Microhydra*, has been found, which bears medusa-buds and is probably the stock from which the medusa is budded. It is a remarkable fact that all specimens of *Limnocodium* hitherto seen have been males; it may be inferred from this either that only one polyp-stock has been introduced into Europe, from which all the medusae seen hitherto have been budded, or perhaps that the female medusa is a sessile gonophore, as in *Pennaria*. The male gonads are carried on the radial canals.

Limnocnida tanganyicae was discovered first in Lake Tanganyika, but has since been discovered also in Lake Victoria and in the river Niger. It differs from *Limnocodium* in having practically no manubrium but a wide mouth two-thirds the diameter of the umbrella across. It buds medusae from the margin of the mouth in May and June, and in August and September the gonads are formed in the place where the buds arose. The hydroid phase, if any, is not known.

Both these medusae have sense-organs of a peculiar type, which are said to contain an endodermal axis like the sense-organs of Trachylinae, but the fact has recently been called in question for

Limnocodium by S. Goto, who considers the genus to be allied to *Olindias*. Allman, on the other hand, referred *Limnocodium* to the Leptomedusae.

In this connexion must be mentioned, finally, the medusae budded from the fresh-water polyp *Microhydra*. The polyp-stages of *Limnocodium* and *Microhydra* are extremely similar in character. In both cases the hydranth is extremely reduced and has no tentacles, and the polyp forms a colony by budding from the base. In *Limnocodium* the body secretes a gelatinous mucus to which adhere particles of mud, &c., forming a protective covering. In *Microhydra* no such protecting case is formed. In view of the great resemblance between *Microhydra* and the polyp of *Limnocodium*, it might be expected that the medusae to which they give origin would also be similar. As yet, however, the medusa of *Microhydra* has only been seen in an immature condition, but it shows some well-marked differences from *Limnocodium*, especially in the structure of the tentacles, which furnish useful characters for distinguishing species amongst medusae. The possession of a polyp-stage by *Limnocodium* and *Microhydra* furnishes an argument against placing them in the Trachylinae. Their sense-organs require renewed investigations. (Browne [10] and [10*a*].)

ORDER VI. **Siphonophora.**—Pelagic floating Hydrozoa with great differentiation of parts, each performing a special function; generally regarded as colonies showing differentiation of individuals in correspondence with a physiological division of labour.

A typical Siphonophore is a stock or *cormus* consisting of a number of *appendages* placed in organic connexion with one another by means of a *coenosarc*. The coenosarc does not differ in structure from that already described in colonial Hydrozoa. It consists of a hollow tube, or tubes, of which the wall is made up of the two body-layers, ectoderm and endoderm, and the cavity is a continuation of the digestive cavities of the nutritive and other appendages, *i.e.* of the coelenteron. The coenosarc may consist of a single elongated tube or stolon, forming the stem or axis of the cormus on which, usually, the appendages are arranged in groups termed *cormidia*; or it may take the form of a compact mass of ramifying, anastomosing tubes, in which case the cormus as a whole has a compact form and cormidia are not distinguishable. In the Disconectae the coenosarc forms a spongy mass, the "*centradenia*," which is partly hepatic in function, forming the so-called liver, and partly excretory.

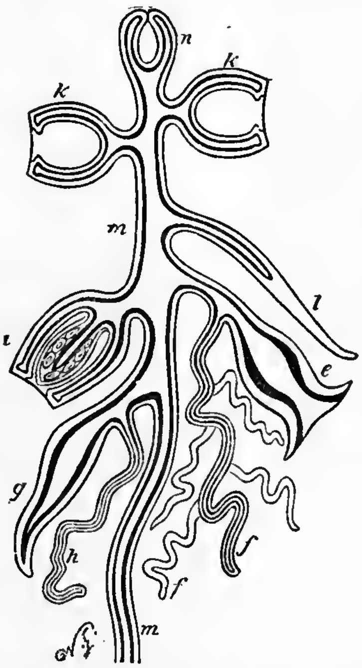


FIG. 68.—Diagram showing possible modifications of medusiform and hydriform persons of a colony of *Siphonophora*. The thick black line represents endoderm, the thinner line ectoderm. (After Allman.)

n, Pneumatocyst.
k, Nectocalyces (swimming bells).
l, Hydrophyllium (covering-piece).
i, Generative medusiform person.
g, Palpon with attached palpacle, *h*.
e, Siphon with branched grappling tentacle, *f*.
m, Stem.

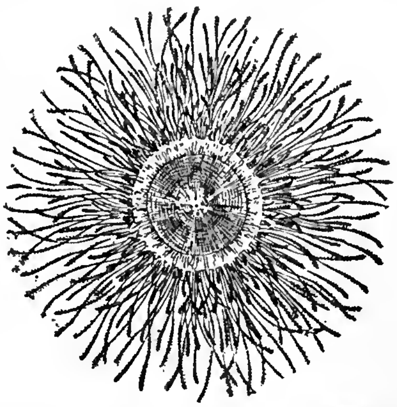
The appendages show various types of form and structure corresponding to different functions. The cormus is always differentiated into two parts; an upper portion termed the *nectosome*, in which the appendages are locomotor or hydrostatic in function, that is to say, serve for swimming or floating; and a lower portion termed the *siphosome*, bearing appendages which are nutritive, reproductive or simply protective in function.

Divergent views have been held by different authors both as regards the nature of the cormus as a whole, and as regards the homologies of the different types of appendages borne by it.

The general theories of Siphonophoran morphology are discussed below, but in enumerating the various types of appendages it is convenient to discuss their morphological interpretation at the same time.

In the nectosome one or more of the following types of appendage occur:—

1. Swimming-bells, termed *nectocalyces* or *nectophores* (fig. 68, *k*), absent in *Chondrophorida* and *Cystophorida*; they are contractile and resemble, both in appearance, structure and function, the umbrella of a medusa, with radial canals, ring-canal and velum; but they are without manubrium, tentacles or sense-organs, and are always bilaterally symmetrical, a peculiarity of form related with the fact that they are attached on one side to the stem. A given cormus may bear one or several nectocalyces, and by their contractions they propel the colony slowly along, like so many medusae harnessed together. In cases where the cormus has no pneumatophore the topmost swimming bell may contain an oil-reservoir or *oleocyst*.



After A. Agassiz, from Lankester's *Treatise on Zoology*.

FIG. 69.—*Porpita*, seen from above, showing the pneumatophore and expanded palpons.

2. The pneumatophore or air-bladder (fig. 68, *n*), for passive locomotion, forming a float which keeps the cormus at or near the surface of the water. The pneumatophore arises from the ectoderm as a pit or invagination, part of which forms a gas-secreting gland, while the rest gives rise to an air-sack lined by a chitinous cuticle. The orifice of invagination forms a pore which may be closed up or may form a protruding duct or funnel. As in the analogous swim-bladder of fishes, the gas in the pneumatophore can be secreted or absorbed, whereby the specific gravity of the body can be diminished or increased, so as to cause it to float nearer the surface or at a deeper level. Never more than one pneumatophore is found in a cormus, and when present it is always situated at the highest point above the swimming bells, if these are present also. In *Velella* the pneumatophore becomes of complex structure and sends air-tubes, lined by a chitin and resembling tracheae, down into the compact coenosarc, thus evidently serving a respiratory as well as a hydrostatic function.

Divergent views have been held as to the morphological significance of the pneumatophore. E. Haeckel regarded the whole structure as a glandular ectodermal pit formed on the exumbral surface of a medusa-person. C. Chun and, more recently, R. Woltereck [59], on the other hand, have shown that the ectodermal pit which gives rise to the pneumatophore represents an entocodon. Hence the cavity of the air-sack is equivalent to a sub-umbral cavity in which no manubrium is formed, and the pore or orifice of invagination would represent the margin of the umbrella. In the wall of the sack is a double layer of endoderm, the space between which is a continuation of the coelenteron. By coalescence of the endoderm-layers, the coelenteron may be reduced to vessels, usually eight in number, opening into a ring-sinus surrounding the pore. Thus the disposition of the endoderm-cavities is roughly comparable to the gastrovascular system of a medusa.

The difference between the theories of Haeckel and Chun is connected with a further divergence in the interpretation of the stem or axis of the cormus. Haeckel regards it as the equivalent of the manubrium, and as it is implanted on the blind end of the pneumatophore, such a view leads necessarily to the air-sack and gland being a development on the ex-umbral surface of the medusa-person. Chun and Woltereck, on the other hand, regard the stem as a *stolo prolifer* arising from the aboral pole, that is to say, from the ex-umbrella, similar to that which grows out from the ex-umbral surface of the embryo of the Narcomedusae and produces buds, a view which is certainly supported by the embryological evidence to be adduced shortly.

In the siphosome the following types of appendages occur:—

1. *Siphons* or nutritive appendages, from which the order takes its name; never absent and usually present in great numbers (fig. 68, *e*). Each is a tube dilated at or towards the base and containing a mouth at its extremity, leading into a stomach placed in the dilatation already mentioned. The siphons have been compared to the manubrium of a medusa-individual, or to polyps, and hence are sometimes termed gastrozoids.

2. *Palpons* (fig. 68, *g*), present in some genera, especially in Physonectae; similar to the siphons but without a mouth, and purely tactile in function, hence sometimes termed dactylozoids. If a distal pore or aperture is present, it is excretory in function; such varieties have been termed "cystons" by Haeckel.

3. *Tentacles* (" *Fangfäden* "), always present, and implanted one at the base of each siphon (fig. 68, *f*). The tentacles of siphonophores may reach a great length and have a complex structure. They may bear accessory filaments or *tentilla* (*f'*), covered thickly with batteries of nematocysts, to which these organisms owe their great powers of offence and defence.

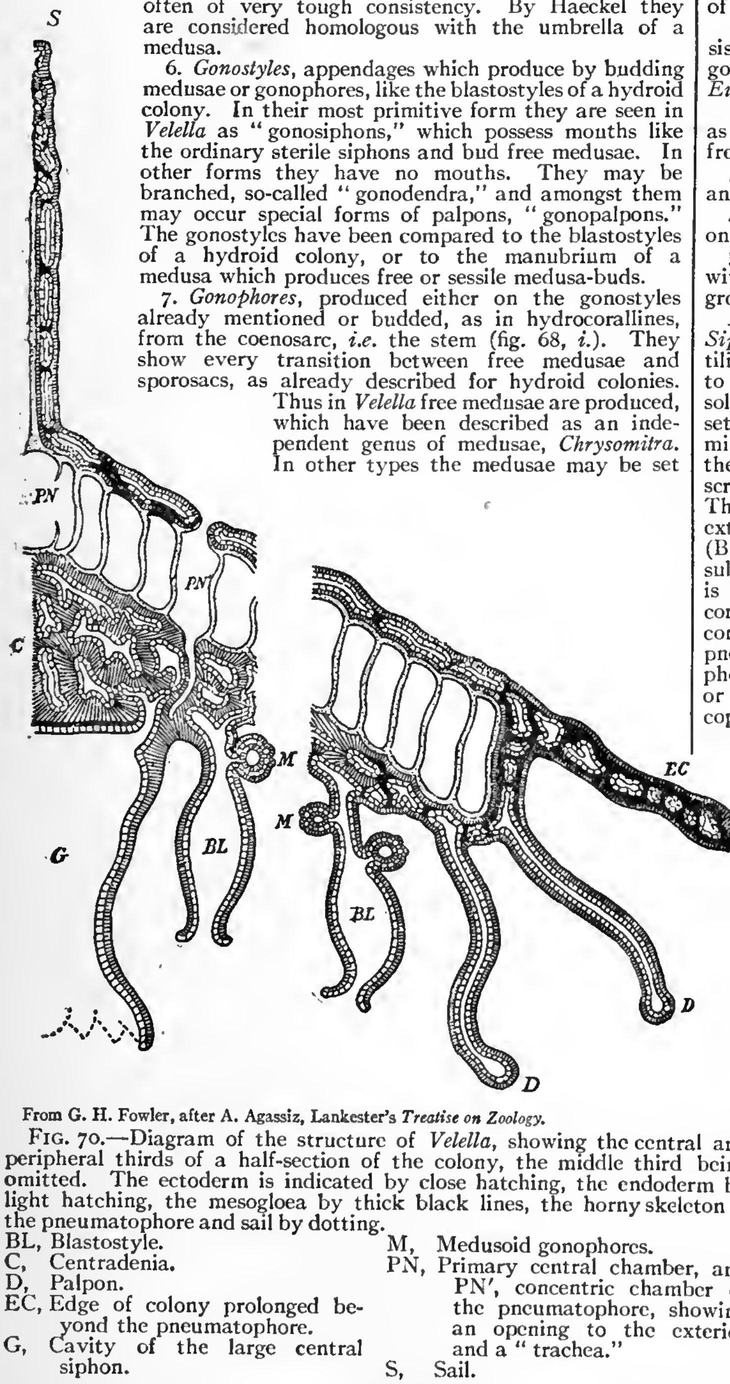
4. *Palpacles* (" *Tastfäden* "), occurring together with palpons, one implanted at the base of each palpon (fig. 68, *h*). Each palpacle is a tactile filament, very extensile, without accessory filaments or nematocysts.

5. *Bracts* (" *hydrophyllia* "), occur in *Calycophorida* and some *Physophorida* as scale-like appendages protecting other parts (fig. 68, *l*). The mesogloea is greatly developed in them and they are often of very tough consistency. By Haeckel they are considered homologous with the umbrella of a medusa.

6. *Gonostyles*, appendages which produce by budding medusae or gonophores, like the blastostyles of a hydroid colony. In their most primitive form they are seen in *Velella* as "gonosiphons," which possess mouths like the ordinary sterile siphons and bud free medusae. In other forms they have no mouths. They may be branched, so-called "gonodendra," and amongst them may occur special forms of palpons, "gonopalpons." The gonostyles have been compared to the blastostyles of a hydroid colony, or to the manubrium of a medusa which produces free or sessile medusa-buds.

7. *Gonophores*, produced either on the gonostyles already mentioned or budded, as in hydrocorallines, from the coenosarc, *i.e.* the stem (fig. 68, *i.*). They show every transition between free medusae and sporosacs, as already described for hydroid colonies. Thus in *Velella* free medusae are produced, which have been described as an independent genus of medusae, *Chrysomitra*. In other types the medusae may be set free in a mature condition as the so-called "genital swimming bells," comparable to the *Globiceps of Pennaria*. The most usual condition, however, is that in which sessile medusoid gonophores or sporosacs are produced.

The various types of appendages described in the foregoing may be arranged in groups termed *cormidia*. In forms with a compact coenosarc such as *Velella*, *Physalia*, &c., the separate cormidia cannot be sharply distinguished, and such a condition is described technically as one with "scattered" cormidia. In forms in which, on the other hand, the coenosarc forms an elongated, tubular axis or stem, the appendages are arranged as regularly recurrent cormidia along it, and the cormidia are then said to be "ordinate." In such cases the oldest cormidia, that is to say, those furthest from the nectosome, may become detached (like the segments or proglottides of a tape-worm) and swim off, each such detached cormidium then becoming a small free cormus which, in many cases, has been given an independent generic name. A cormidium may contain a single nutritive siphon (" monogastric ") or several siphons (" polygastric ").



From G. H. Fowler, after A. Agassiz, Lankester's *Treatise on Zoology*.

FIG. 70.—Diagram of the structure of *Velella*, showing the central and peripheral thirds of a half-section of the colony, the middle third being omitted. The ectoderm is indicated by close hatching, the endoderm by light hatching, the mesogloea by thick black lines, the horny skeleton of the pneumatophore and sail by dotting.

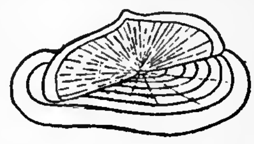
S, Sail.



From G. H. Fowler, after G. Cuvier, Lankester's *Treatise on Zoology*.

FIG. 71.—Upper surface of *Velella*, showing pneumatophore and sail.

The following are some of the forms of cormidia that occur:—

1. The *eudoxome* (Calycophorida), consisting of a bract, siphon, tentacle and gonophore; when free it is known as *Eudoxia*.

2. The *ersaeome* (Calycophorida), made up of the same appendages as the preceding type but with the addition of a nectocalyx; when free termed *Ersaea*.

3. The *rhodalome* of some *Rhodalidae*, consisting of siphon, tentacle and one or more gonophores.

4. The *athorome* of *Physophora*, &c., consisting of siphon, tentacle, one or more palpons with palpacles, and one or more gonophores.

5. The *crystallome* of *Anthemodes*, &c., similar to the athorome but with the addition of a group of bracts.

Embryology of the Siphonophora.—The fertilized ovum gives rise to a parenchymula, with solid endoderm, which is set free as a free-swimming planula larva, in the manner already described (see HYDROZOA). The planula has its two extremities dissimilar (Bipolaria-larva). The subsequent development is slightly different according as the future cormus is headed by a pneumatophore (Physophorida, Cystophorida) or by a nectocalyx (Calycophorida).

(i.) Physophorida, for example *Halistemma* (C. Chun, HYDROZOA [1]). The planula becomes elongated and broader towards one pole, at which a pit or invagination of the ectoderm arises. Next the pit closes up to form a vesicle with a pore, and so gives rise to the pneumatophore. From the broader portion of the planula an outgrowth arises which becomes the first tentacle of the cormus. The endoderm of the planula now acquires a cavity, and at the narrower pole a mouth is formed, giving rise to the primary siphon. Thus from the original planula three appendages are, as it were, budded off, while the planula itself mostly gives rise to coenosarc, just as in some hydroids the planula is converted chiefly into hydrorhiza.

(ii.) Calycophorida, for example, *Muggiaea*. The planula develops, on the whole, in a similar manner, but the ectodermal invagination arises, not at the pole of the planula, but on the side of its broader portion, and gives rise, not to a pneumatophore, but to a nectocalyx, the primary swimming bell or *protocodon* (" *Fallschirm* ") which is later thrown off and replaced by secondary swimming bells, *metacodons*, budded from the coenosarc.

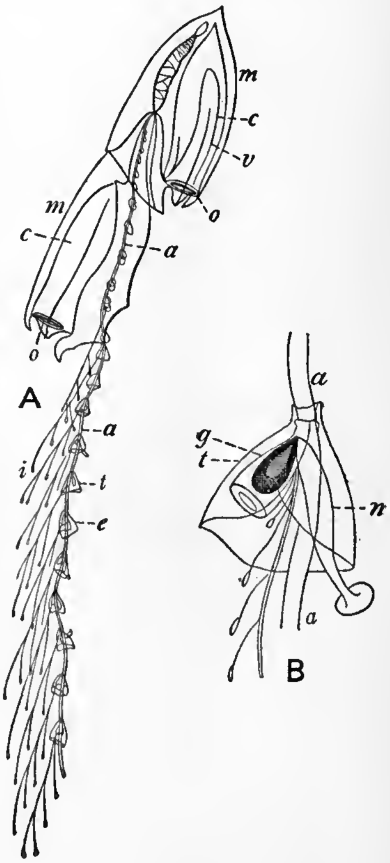


FIG. 72.—A, *Diphyes campanulata*; B, a group of appendages (cormidium) of the same *Diphyes*. (After C. Gegenbaur.)

a, Axis of the colony.

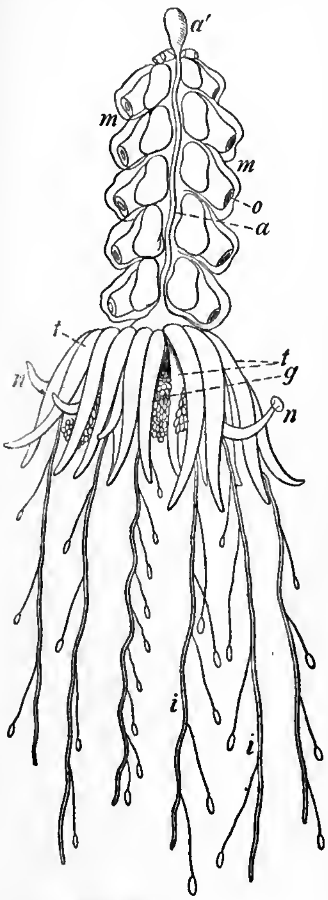
v, Radial canals of nectocalyx.
o, Orifice of nectocalyx.
t, Bract.
n, Siphon.
g, Gonophore.
i, Tentacle.

From a comparison of the two embryological types there can be no doubt on two points; first, that the pneumatophore and the protocodon are strictly homologous, and, therefore if the nectocalyx is comparable to the umbrella of a medusa, as seems obvious, the pneumatophore must be so too; secondly, that the coenosarcal axis arises from the ex-umbrella of the medusa and cannot be compared to a manubrium, but is strictly comparable to the "bud-spike" of a Narcomedusan.

Theories of Siphonophore Morphology.—The many theories that have been put forward as to the interpretation of the cormus and the various parts are set forth and discussed in the treatise of Y. Delage and E. Hérouard (HYDROZOA [4]) and more recently by R. Woltereck [59], and only a brief analysis can be given here.

In the first place the cormus has been regarded as a single individual and its appendages as *organs*. This is the so-called "polyorgan" theory, especially connected with the name of Huxley; but it must be borne in mind that Huxley regarded all the forms produced, in any animal, between one egg-generation and the next, as constituting in the lump one single individual. Huxley, therefore, considered a hydroid colony, for example, as a single individual, and each separate polyp or medusa budded from it as having the value of an organ and not of an individual. Hence Huxley's view is not so different from those held by other authors as it seems to be at first sight.



After C. Gegenbaur.

- *i*, Tentacle.

In more recent years Woltereck [59] has supported Huxley's view of individuality, at the same time drawing a fine distinction between "individual" and "person." The individual is the product of sexual reproduction; a person is an individual of lower rank, which may be produced asexually. A Siphonophore is regarded as a single individual composed of numerous zoids, budded from the primary zoid (siphon) produced from the planula. Any given zoid is a person-zoid if equivalent to the primary zoid, an organ-zoid if equivalent only to a part of it. Woltereck considers the siphonophores most nearly allied to the Narcomedusae, producing like the buds from an aboral stolon, the first bud being represented by the pneumatophore or protocodon, in different cases.

Contrasting, in the second place, with the polyorgan theory are the various "polyperson" theories which interpret the Siphonophore cormus as a colony composed of more or fewer individuals in organic union with one another. On this interpretation there is still room for considerable divergence of opinion as regards detail. To begin with, it is not necessary on the polyperson theory to regard each appendage as a distinct individual; it is still possible to compare appendages with parts of an individual which have become separated from one another by a process of "dislocation of organs." Thus a bract may be regarded, with Haeckel, as a modified umbrella of a medusa, a siphon as its manubrium, and a tentacle as representing a medusan tentacle shifted in attachment from the margin to the sub-umbrella; or a siphon may be compared with a polyp, of which the single tentacle has become shifted so as to be attached to the coenosarc and so on. Some authors prefer, on the other hand, to regard every appendage as a separate individual, or at least as a portion of an individual, of which other portions have been lost or obliterated.

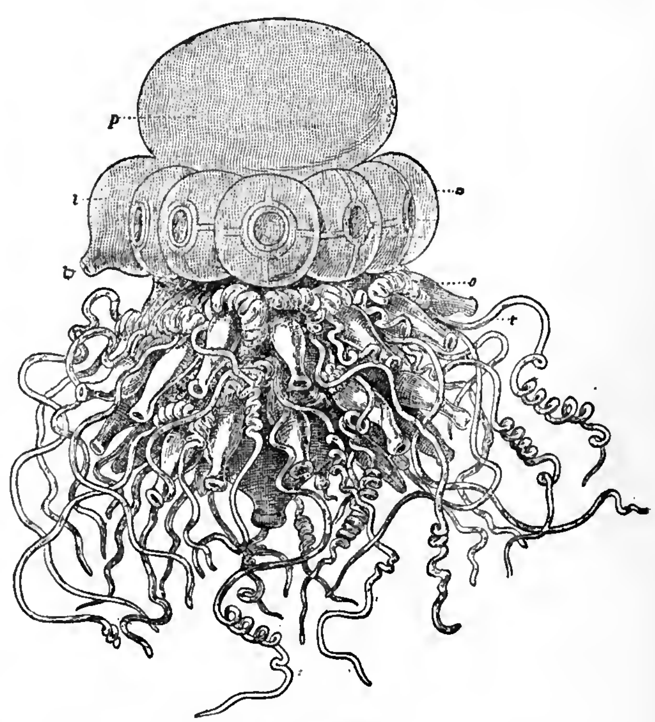
A further divergence of opinion arises from differences in the interpretation of the persons composing the colony. It is possible to regard the cormus (1) as a colony of medusa-persons, (2) as a colony of polyp-persons, (3) as composed partly of one, partly of the other. It is sufficient here to mention briefly the views put forward on this point by C. Chun and E. Haeckel.

Chun (HYDROZOA [1]) maintains the older views of Leuckart and Claus, according to which the cormus is to be compared to a floating hydroid colony. It may be regarded as derived from floating polyps similar to *Nemopsis* or *Pelagohydra*, which by budding produce a colony of polyps and also form medusa-buds. The polyp-individuals form the nutritive siphosome or trophosome. The medusa-buds are either fertile or sterile. If fertile they become free medusae or sessile gonophores. If sterile they remain attached and locomotor in function, forming the nectosome, the pneumatophore and swimming-bells.

Haeckel, on the other hand, is in accordance with Balfour in regarding a Siphonophore as a medusome, that is to say, as a colony composed of medusoid persons or organs entirely. Haeckel considers that the Siphonophores have two distinct ancestral lines of evolution:

1. In the *Disconanthae*, *i.e.* in such forms as *Velella*, *Porpita*, &c., the ancestor was an eight-rayed medusa (*Disconula*) which acquired a pneumatophore as an ectodermal pit on the ex-umbrella, and in which the organs (manubrium, tentacles, &c.) became secondarily multiplied, just as they do in *Gastroblasta* as the result of incomplete fission. The nearest living allies of the ancestral *Disconula* are to be sought in the *Pectyllidae*.

2. In the *Siphonanthae*, *i.e.* in all other Siphonophores, the ancestral form was a *Siphonula*, a bilaterally symmetrical Anthomedusa



After Haeckel, from Lankester's *Treatise on Zoology*.

FIG. 74.—*Stephalia corona*, a young colony.

n, Nectocalyx.	*lo*, Orifice of the aurophore.	*t*, Tentacle.

with a single long tentacle (cf. *Corymorpha*), which became displaced from the margin to the sub-umbrella. The *Siphonula* produced buds on the manubrium, as many Anthomedusae are known to do, and these by reduction or dislocation of parts gave rise to the various appendages of the colony. Thus the umbrella of the *Siphonula* became the protocodon, and its manubrium, the axis or stolon, which, by a process of dislocation of organs, escaped, as it were, from the sub-umbrella through a cleft and became secondarily attached to the ex-umbrella. It must be pointed out that, however probable Haeckel's theory may be in other respects, there is not the slightest evidence for any such cleft in the umbrella having been present at any time, and that the embryological evidence, as already pointed out, is all against any homology between the stem and a manubrium, since the primary siphon does not become the stem, which arises from the ex-umbral side of the protocodon and is strictly comparable to a stolon.

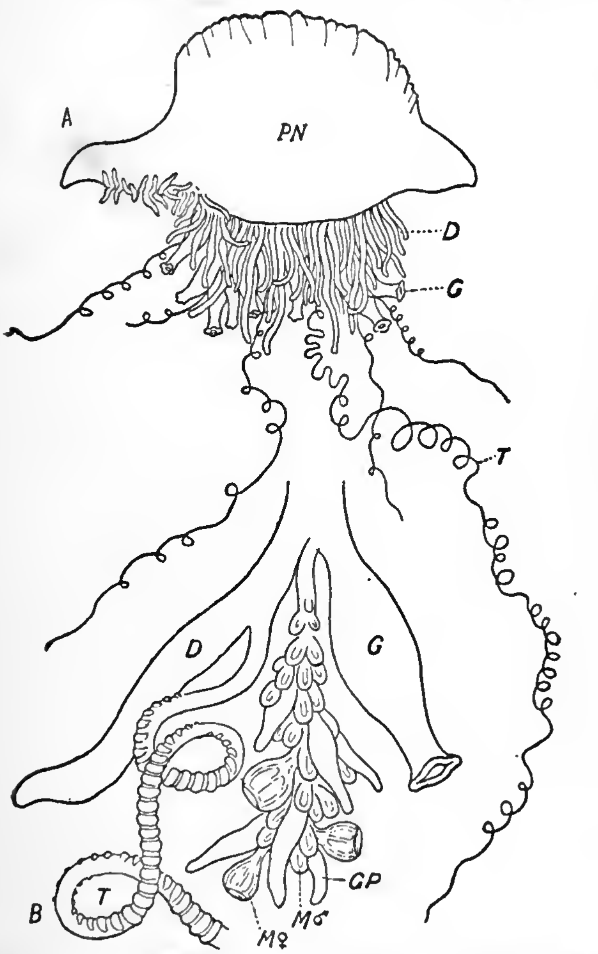
Classification.—The Siphonophora may be divided, following Delage and Hérouard, into four sub-orders:

I. CHONDROPHORIDA (*Disconeclae* Haeckel, *Tracheophysae* Chun). With an apical chambered pneumatophore, from which tracheal tubes may take origin (fig. 70); no nectocalyces or bracts; appendages all on the lower side of the pneumatophore arising from a compact coenosarc, and consisting of a central principal siphon, surrounded by gonosiphons, and these again by tentacles.

Three families: (1) *Discalidae*, for *Discalia* and allied genera, deep-sea forms not well known; (2) *Porpitidae* for the familiar genus *Porpita* (fig. 69) and its allies; and (3) *Velellidae*, represented by the well-known genus *Velella* (figs. 70, 71), common in the Mediterranean and other seas.

II. Calycophorida (*Calyconectae*, Haeckel). Without pneumatophore, with one, two, rarely more nectocalyces.

Three families: (1) *Monophyidae*, with a single nectocalyx; examples *Muggiaea*, sometimes found in British seas, *Sphaeronectes*, &c.; (2) *Diphyidae*, with two nectocalyces; examples *Diphyes* (fig. 72), *Praya*, *Abyla*, &c.; and (3) *Polyphyidae*, with numerous nectocalyces; example *Hippopodius*, *Stephanophyes* and other genera.



From G. H. Fowler, modified after G. Cuvier and E. Haeckel, Lankester's *Treatise on Zoology*.

Fig. 75.—A. *Physalia*, general view, diagrammatic; B, cormidium of *Physalia*; D, palpon; T, palpacle; G, siphon; GP, gonopalpon; M ♂, male gonophore; M ♀, female gonophore, ultimately set free.

III. Physophorida (*Physonectae* + *Auronectae*, Haeckel). With an apical pneumatophore, not divided into chambers, followed by a series of nectocalyces or bracts.

A great number of families and genera are referred to this group, amongst which may be mentioned specially—(1) *Agalmidae*, containing the genera *Stephanomia*, *Agalma*, *Anthemodes*, *Halistemma*, &c.; (2) *Apolemidae*, with the genus *Apolemia* and its allies; (3) *Forskaliidae*, with *Forskalia* and allied forms; (4) *Physophoridae*, for *Physophora* (fig. 73) and other genera, (5) *Anthophysidae*, for *Anthophysa*, *Athorybia*, &c.; and lastly the two families (6) *Rhodalidae* and (7) *Stephalidae* (fig. 74), constituting the group Auronectae of Haeckel. The Auronectae are peculiar deep-sea forms, little known except from Haeckel's descriptions, in which the large pneumatophore has a peculiar duct, termed the aurophore, placed on its lower side in the midst of a circle of swimming-bells.

IV. Cystophorida (*Cystonectae*, Haeckel). With a very large pneumatophore not divided into chambers, but without nectocalyces or bracts. Two sections can be distinguished, the Rhizophysina, with long tubular coenosarc-bearing ordinate cormidia, and Physalina, with compact coenosarc-bearing scattered cormidia.

A type of the Rhizophysina is the genus *Rhizophysa*. The Physalina comprise the families *Physalidae* and *Epibulidae*, of which the types are *Physalia* (figs. 74, 75) and *Epibulia*, respectively. *Physalia*, known commonly as the Portuguese man-of-war, is remarkable for its great size, its brilliant colours, and its terrible stinging powers.

HYDROMETER (Gr. ὕδωρ, water, and μέτρον, a measure), an instrument for determining the density of bodies, generally of fluids, but in some cases of solids. When a body floats in a fluid under the action of gravity, the weight of the body is equal to that of the fluid which it displaces (see HYDROMECHANICS). It is upon this principle that the hydrometer is constructed, and it obviously admits of two modes of application in the case of fluids: either we may compare the weights of floating bodies which are capable of displacing the same volume of different fluids, or we may compare the volumes of the different fluids which are displaced by the same weight. In the latter case, the densities of the fluids will be inversely proportional to the volumes thus displaced.

The hydrometer is said by Synesius Cyreneus in his fifth letter to have been invented by Hypatia at Alexandria,[1] but appears to have been neglected until it was reinvented by Robert Boyle, whose "New Essay Instrument," as described in the *Phil. Trans.* for June 1675, differs in no essential particular from Nicholson's hydrometer. This instrument was devised for the purpose of detecting counterfeit coin, especially guineas and half-guineas. In the first section of the paper (*Phil. Trans.* No. 115, p. 329) the author refers to a glass instrument exhibited by himself many years before, and "consisting of a bubble furnished with a long and slender stem, which was to be put into several liquors, to compare and estimate their specific gravities." This seems to be the first reference to the hydrometer in modern times.

In fig. 1 C represents the instrument used for guineas, the circular plates A representing plates of lead, which are used as ballast when lighter coins than guineas are examined. B represents "a small glass instrument for estimating the specific gravities of liquors," an account of which was promised by Boyle in the following number of the *Phil. Trans.*, but did not appear.

The instrument represented at B (fig. 1), which is copied from Robert Boyle's sketch in the *Phil. Trans.* for 1675, is generally known as the common hydrometer. It is usually made of glass, the lower bulb being loaded with mercury or small shot which serves as ballast, causing the instrument to float with the stem vertical. The quantity of mercury or shot inserted depends upon the density of the liquids for which the hydrometer is to be employed, it being essential that the whole of the bulb should be immersed in the heaviest liquid for which the instrument is used, while the length and diameter of the stem must be such that the hydrometer will float in the lightest liquid for which it is required. The stem is usually divided into a number of equal parts, the divisions of the scale being varied in different instruments, according to the purposes for which they are employed.

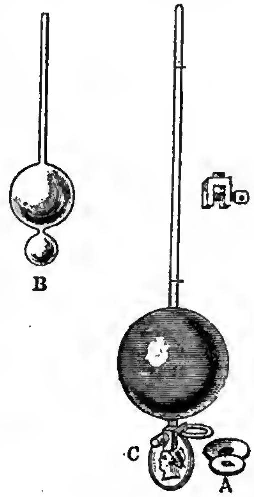

FIG. 1.—Boyle's New Essay Instrument.

Let V denote the volume of the instrument immersed (*i.e.* of liquid displaced) when the surface of the liquid in which the hydrometer floats coincides with the lowest division of the scale, A the area of the transverse section of the stem, l the length of a scale division, n the number of divisions on the stem, and W the weight of the instrument. Suppose the successive divisions of the scale to be numbered 0, 1, 2 . . . n starting with the lowest, and let w_0, w_1, w_2 . . . w_n be the weights of unit volume of the liquids in which the hydrometer sinks to the divisions 0, 1, 2 . . . n respectively. Then, by the principle of Archimedes,

$$W = Vw_0;\ \text{or}\ w_0 = W/V.\quad \text{Also}$$
$$W = (V + lA)w_1;\ \text{or}\ w_1 = W/(V + lA),$$
$$w_p = W/(V + plA),\ \text{and}$$
$$w_n = W/(V + nlA),$$

or the densities of the several liquids vary inversely as the respective volumes of the instrument immersed in them; and, since the divisions of the scale correspond to equal increments of volume immersed, it follows that the densities of the several liquids in which the instrument sinks to the successive divisions form a harmonic series.

If $V = NlA$ then N expresses the ratio of the volume of the instrument up to the zero of the scale to that of one of the scale-divisions. If we suppose the lower part of the instrument replaced by a uniform bar of the same sectional area as the stem and of volume V, the indications of the instrument will be in no respect altered, and the bottom of the bar will be at a distance of N scale-divisions below the zero of the scale.

In this case we have $w_p = W/(N+p)lA$; or the density of the liquid varies inversely as $N+p$, that is, as the whole number of scale-divisions between the bottom of the tube and the plane of flotation.

If we wish the successive divisions of the scale to correspond to equal increments in the density of the corresponding liquids, then the volumes of the instrument, measured up to the successive divisions of the scale, must form a series in harmonical progression, the lengths of the divisions increasing as we go up the stem.

The greatest density of the liquid for which the instrument described above can be employed is W/V, while the least density is $W/(V+nlA)$, or $W/(V+v)$, where v represents the volume of the stem between the extreme divisions of the scale. Now, by increasing v, leaving W and V unchanged, we may increase the range of the instrument indefinitely. But it is clear that if we increase A, the sectional area of the stem, we shall diminish l, the length of a scale-division corresponding to a given variation of density, and thereby proportionately diminish the sensibility of the instrument, while diminishing the section A will increase l and proportionately increase the sensibility, but will diminish the range over which the instrument can be employed, unless we increase the length of the stem in the inverse ratio of the sectional area. Hence, to obtain great sensibility along with a considerable range, we require very long slender stems, and to these two objections apply in addition to the question of portability; for, in the first place, an instrument with a very long stem requires a very deep vessel of liquid for its complete immersion, and, in the second place, when most of the stem is above

[1] In *Nicholson's Journal*, iii. 89, Citizen Eusebe Salverte calls attention to the poem "De Ponderibus et Mensuris" generally ascribed to Rhemnius Fannius Palaemon, and consequently 300 years older than Hypatia, in which the hydrometer is described and attributed to Archimedes.

the plane of flotation, the stability of the instrument when floating will be diminished or destroyed. The various devices which have been adopted to overcome this difficulty will be described in the account given of the several hydrometers which have been hitherto generally employed.

The plan commonly adopted to obviate the necessity of inconveniently long stems is to construct a number of hydrometers as nearly alike as may be, but to load them differently, so that the scale-divisions at the bottom of the stem of one hydrometer just overlap those at the top of the stem of the preceding. By this means a set of six hydrometers, each having a stem rather more than 5 in. long, will be equivalent to a single hydrometer with a stem of 30 in. But, instead of employing a number of instruments differing only in the weights with which they are loaded, we may employ the same instrument, and alter its weight either by adding mercury or shot to the interior (if it can be opened) or by attaching weights to the exterior. These two operations are not quite equivalent, since a weight added to the interior does not affect the volume of liquid displaced when the instrument is immersed up to a given division of the scale, while the addition of weights to the exterior increases the displacement. This difficulty may be met, as in Keene's hydrometer, by having all the weights of precisely the same volume but of different masses, and never using the instrument except with one of these weights attached.

The first hydrometer intended for the determination of the densities of liquids, and furnished with a set of weights to be attached when necessary, was that constructed by Mr Clarke (instrument-maker) and described by J. T. Desaguliers in the *Philosophical Transactions* for March and April 1730, No. 413, p. 278. The following is Desaguliers's account of the instrument (fig. 2):—

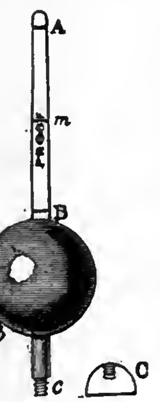

Fig. 2.—Clarke's Hydrometer.

"After having made several fruitless trials with ivory, because it imbibes spirituous liquors, and thereby alters its gravity, he (Mr Clarke) at last made a copper hydrometer, represented in fig. 2, having a brass wire of about 1 in. thick going through, and soldered into the copper ball B*b*. The upper part of this wire is filed flat on one side, for the stem of the hydrometer, with a mark at *m*, to which it sinks exactly in proof spirits. There are two other marks, A and B, at top and bottom of the stem, to show whether the liquor be $\frac{1}{10}$th above proof (as when it sinks to A), or $\frac{1}{10}$th under proof (as when it emerges to B), when a brass weight such as C has been screwed on to the bottom at *c*. There are a great many such weights, of different sizes, and marked to be screwed on instead of C, for liquors that differ more than $\frac{1}{10}$th from proof, so as to serve for the specific gravities in all such proportions as relate to the mixture of spirituous liquors, in all the variety made use of in trade. There are also other balls for showing the specific gravities quite to common water, which make the instrument perfect in its kind."

Clarke's hydrometer, as afterwards constructed for the purposes of the excise, was provided with thirty-two weights to adapt it to spirits of different specific gravities, and eleven smaller weights, or "weather weights" as they were called, which were attached to the instrument in order to correct for variations of temperature. The weights were adjusted for successive intervals of 5° F., but for degrees intermediate between these no additional correction was applied. The correction for temperature thus afforded was not sufficiently accurate for excise purposes, and William Speer in his essay on the hydrometer (Tilloch's *Phil. Mag.*, 1802, vol. xiv.) mentions cases in which this imperfect compensation led to the extra duty payable upon spirits which were more than 10% over proof being demanded on spirits which were purposely diluted to below 10% over proof in order to avoid the charge. Clarke's hydrometer, however, remained the standard instrument for excise purposes from 1787 until it was displaced by that of Sikes.

Desaguliers himself constructed a hydrometer of the ordinary type for comparing the specific gravities of different kinds of water (Desaguliers's *Experimental Philosophy*, ii. 234). In order to give great sensibility to the instrument, the large glass ball was made nearly 3 in. in diameter, while the stem consisted of a wire 10 in. in length and only $\frac{1}{40}$ in. in diameter. The instrument weighed 4000 grains, and the addition of a grain caused it to sink through an inch. By altering the quantity of shot in the small balls the instrument could be adapted for liquids other than water.

To an instrument constructed for the same purpose, but on a still larger scale than that of Desaguliers, A. Deparcieux added a small dish on the top of the stem for the reception of the weights necessary to sink the instrument to a convenient depth. The effect of weights placed in such a dish or pan is of course the same as if they were placed within the bulb of the instrument, since they do not alter the volume of that part which is immersed.

The first important improvement in the hydrometer after its reinvention by Boyle was introduced by G. D. Fahrenheit, who adopted the second mode of construction above referred to, arranging his instrument so as always to displace the same volume of liquid, its weight being varied accordingly. Instead of a scale, only a single mark is placed upon the stem, which is very slender, and bears at the top a small scale pan into which weights are placed until the instrument sinks to the mark upon its stem. The volume of the displaced liquid being then always the same, its density will be proportional to the whole weight supported, that is, to the weight of the instrument together with the weights required to be placed in the scale pan.

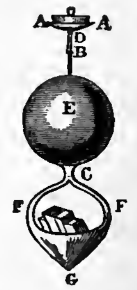

Fig. 3.—Nicholson's Hydrometer.

Nicholson's hydrometer (fig. 3) combines the characteristics of Fahrenheit's hydrometer and of Boyle's essay instrument.[1] The following is the description given of it by W. Nicholson in the *Manchester Memoirs*, ii. 374:—

"AA represents a small scale. It may be taken off at D. Diameter $1\frac{1}{2}$ in., weight 44 grains.

"B a stem of hardened steel wire. Diameter $\frac{1}{100}$ in.

"E a hollow copper globe. Diameter $2\frac{8}{10}$ in. Weight with stem 369 grains.

"FF a stirrup of wire screwed to the globe at C.

"G a small scale, serving likewise as a counterpoise. Diameter $1\frac{1}{2}$ in. Weight with stirrup 1634 grains.

"The other dimensions may be had from the drawing, which is one-sixth of the linear magnitude of the instrument itself.

"In the construction it is assumed that the upper scale shall constantly carry 1000 grains when the lower scale is empty, and the instrument sunk in distilled water at the temperature of 60° Fahr. to the middle of the wire or stem. The length of the stem is arbitrary, as is likewise the distance of the lower scale from the surface of the globe. But, the length of the stem being settled, the lower scale may be made lighter, and, consequently, the globe less, the greater its distance is taken from the surface of the globe; and the contrary."

In comparing the densities of different liquids, it is clear that this instrument is precisely equivalent to that of Fahrenheit, and must be employed in the same manner, weights being placed in the top scale only until the hydrometer sinks to the mark on the wire, when the specific gravity of the liquid will be proportional to the weight of the instrument together with the weights in the scale.

In the subsequent portion of the paper above referred to, Nicholson explains how the instrument may be employed as a thermometer, since, fluids generally expanding more than the solids of which the instrument is constructed, the instrument will sink as the temperature rises.

To determine the density of solids heavier than water with this instrument, let the solid be placed in the upper scale pan, and let the weight now required to cause the instrument to sink in distilled water at standard temperature to the mark B be denoted by w, while W denotes the weight required when the solid is not present. Then $W-w$ is the weight of the solid. Now let the solid be placed in the lower pan, care being taken that no bubbles of air remain attached to it, and let w_1 be the weight now required in the scale pan. This weight will exceed w in consequence of the water displaced by the solid, and the weight of the water thus displaced will be w_1-w, which is therefore the weight of a volume of water equal to that of the solid. Hence, since the weight of the solid itself is $W-w$, its density must be $(W-w)/(w_1-w)$.

The above example illustrates how Nicholson's or Fahrenheit's hydrometer may be employed as a weighing machine for small weights.

In all hydrometers in which a part only of the instrument

[1] *Nicholson's Journal*, vol. i. p. 111, footnote.

is immersed, there is a liability to error in consequence of the surface tension, or capillary action, as it is frequently called, along the line of contact of the instrument and the surface of the liquid (see CAPILLARY ACTION). This error diminishes as the diameter of the stem is reduced, but is sensible in the case of the thinnest stem which can be employed, and is the chief source of error in the employment of Nicholson's hydrometer, which otherwise would be an instrument of extreme delicacy and precision. The following is Nicholson's statement on this point:—

"One of the greatest difficulties which attends hydrostatical experiments arises from the attraction or repulsion that obtains at the surface of the water. After trying many experiments to obviate the irregularities arising from this cause, I find reason to prefer the simple one of carefully wiping the whole instrument, and especially the stem, with a clean cloth. The weights in the dish must not be esteemed accurate while there is either a cumulus or a cavity in the water round the stem."

It is possible by applying a little oil to the upper part of the bulb of a common or of a Sikes's hydrometer, and carefully placing it in pure water, to cause it to float with the upper part of the bulb and the whole of the stem emerging as indicated in fig. 4, when it ought properly to sink almost to the top of the stem, the surface tension of the water around the circumference of the circle of contact, AA′, providing the additional support required.

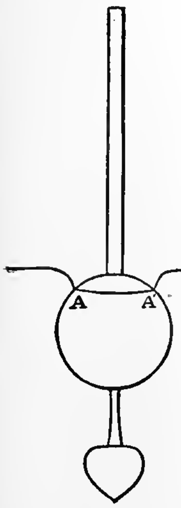

FIG. 4.

The universal hydrometer of G. Atkins, described in the *Phil. Mag.* for 1808, xxxi. 254, is merely Nicholson's hydrometer with the screw at C projecting through the collar into which it is screwed, and terminating in a sharp point above the cup G. To this point soft bodies lighter than water (which would float if placed in the cup) could be attached, and thus completely immersed. Atkins's instrument was constructed so as to weigh 700 grains, and when immersed to the mark on the stem in distilled water at 60° F. it carried 300 grains in the upper dish. The hydrometer therefore displaced 1000 grains of distilled water at 60° F. and hence the specific gravity of any other liquid was at once indicated by adding 700 to the number of grains in the pan required to make the instrument sink to the mark on the stem. The small divisions on the scale corresponded to differences of $\frac{1}{10}$th of a grain in the weight of the instrument.

The "Gravimeter," constructed by Citizen Guyton and described in *Nicholson's Journal*, 4to, i. 110, differs from Nicholson's instrument in being constructed of glass, and having a cylindrical bulb about 21 centimetres in length and 22 millimetres in diameter. Its weight is so adjusted that an additional weight of 5 grammes must be placed in the upper pan to cause the instrument to sink to the mark on the stem in distilled water at the standard temperature. The instrument is provided with an additional piece, or "plongeur," the weight of which exceeds 5 grammes by the weight of water which it displaces; that is to say, it is so constructed as to weigh 5 grammes in water, and consists of a glass envelope filled with mercury. It is clear that the effect of this "plongeur," when placed in the lower pan, is exactly the same as that of the 5 gramme weight in the upper pan. Without the extra 5 grammes the instrument weighs about 20 grammes, and therefore floats in a liquid of specific gravity ·8. Thus deprived of its additional weight it may be used for spirits. To use the instrument for liquids of much greater density than water additional weights must be placed in the upper pan, and the "plongeur" is then placed in the lower pan for the purpose of giving to the instrument the requisite stability.

Charles's balance areometer is similar to Nicholson's hydrometer, except that the lower basin admits of inversion, thus enabling the instrument to be employed for solids lighter than water, the inverted basin serving the same purpose as the pointed screw in Atkins's modification of the instrument.

Adie's sliding hydrometer is of the ordinary form, but can be adjusted for liquids of widely differing specific gravities by drawing out a sliding tube, thus changing the volume of the hydrometer while its weight remains constant.

The hydrometer of A. Baumé, which has been extensively used in France, consists of a common hydrometer graduated in the following manner. Certain fixed points were first determined upon the stem of the instrument. The first of these was found by immersing the hydrometer in pure water, and marking the stem at the level of the surface. This formed the zero of the scale. Fifteen standard solutions of pure common salt in water were then prepared, containing respectively 1, 2, 3, . . . 15% (by weight) of dry salt. The hydrometer was plunged in these solutions in order, and the stem having been marked at the several surfaces, the degrees so obtained were numbered 1, 2, 3, . . . 15. These degrees were, when necessary, repeated along the stem by the employment of a pair of compasses till 80 degrees were marked off. The instrument thus adapted to the determination of densities exceeding that of water was called the hydrometer for salts.

The hydrometer intended for densities less than that of water, or the hydrometer for spirits, is constructed on a similar principle. The instrument is so arranged that it floats in pure water with most of the stem above the surface. A solution containing 10% of pure salt is used to indicate the zero of the scale, and the point at which the instrument floats when immersed in distilled water at 10° R. (54½° F.) is numbered 10. Equal divisions are then marked off upwards along the stem as far as the 50th degree.

The densities corresponding to the several degrees of Baumé's hydrometer are given by Nicholson (*Journal of Philosophy*, i. 89) as follows:—

Baumé's Hydrometer for Spirits. Temperature 10° R.

Degrees.	Density.	Degrees.	Density.	Degrees.	Density.
10	1·000	21	·922	31	·861
11	·990	22	·915	32	·856

24	1·200				

Cartier's hydrometer was very similar to that of Baumé, Cartier having been employed by the latter to construct his instruments for the French revenue. The point at which the instrument floated in distilled water was marked 10° by Cartier, and 30° on Cartier's scale corresponded to 32° on Baumé's.

Perhaps the main object for which hydrometers have been constructed is the determination of the value of spirituous liquors, chiefly for revenue purposes. To this end an immense variety of hydrometers have been devised, differing mainly in the character of their scales.

In Speer's hydrometer the stem has the form of an octagonal prism, and upon each of the eight faces a scale is engraved, indicating the percentage strength of the spirit corresponding to the several divisions of the scale, the eight scales being adapted respectively to the temperature 35°, 40°, 45°, 50°, 55°, 60°, 65° and 70° F. Four small pins, which can be inserted into the counterpoise of the instrument, serve to adapt the instrument to the temperatures intermediate between those for which the scales are constructed. William Speer was supervisor and chief assayer of spirits in the port of Dublin. For a more complete account of this instrument see Tilloch's *Phil. Mag.*, xiv. 151.

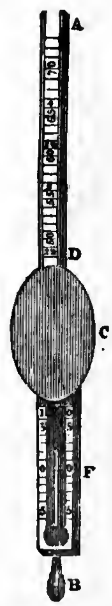

FIG. 5.—Jones's Hydrometer.

The hydrometer constructed by Jones, of Holborn, consists of a spheroidal bulb with a rectangular stem (fig. 5). Between the bulb and counterpoise is placed a thermometer, which serves to indicate the temperature of the liquid, and the instrument is provided with three weights which can be attached to the top of the stem. On the four sides of the stem AD are engraved four scales corresponding respectively to the unloaded instrument, and to the instrument loaded with the respective weights. The instrument when unloaded serves for the range from 74 to 47 over proof; when loaded with the first weight it indicates from 46 to 13 over proof, with the second weight from 13 over proof to 29 under proof, and with the third from 29 under proof to pure water, the graduation corresponding to which is marked W at the bottom of the fourth scale. One side of the stem AD is shown in fig. 5, the other three in fig. 6. The thermometer is also provided with four scales corresponding to the scales above mentioned. Each scale has its zero in the middle corresponding to 60° F. If the mercury in the thermometer stand above this zero the spirit must be reckoned weaker than the hydrometer indicates by the number on the thermometer scale level with the top of the mercury, while if the thermometer indicate a temperature lower than the zero of the scale (60° F.) the spirit must be reckoned stronger by the scale reading. At the side of each of the four scales on the stem of the hydrometer is engraved a set of small numbers indicating the contraction in volume which would be experienced if the requisite amount of water (or spirit) were added to bring the sample tested to the proof strength.

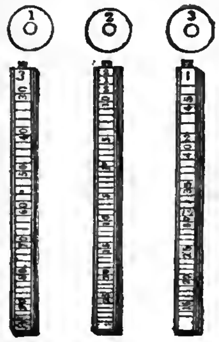

FIG. 6.

The hydrometer constructed by Dicas of Liverpool is provided with a sliding scale which can be adjusted for different temperatures, and which also indicates the contraction in volume incident on bringing the spirit to proof strength. It is provided with thirty-six different weights which, with the ten divisions on the stem, form a scale from 0 to 370. The employment of so many weights renders the instrument ill-adapted for practical work where speed is an object.

This instrument was adopted by the United States in 1790, but was subsequently discarded by the Internal Revenue Service for another type. In this latter form the observations have to be made at the standard temperature of 60° F., at which the graduation 100 corresponds to proof spirit and 200 to absolute alcohol. The need of adjustable weights is avoided by employing a set of five instruments, graduated respectively 0°-100°, 80°-120°, 100°-140°, 130°-170°, 160°-200°. The reading gives the volume of proof spirit equivalent to the volume of liquor; thus the readings 80° and 120° mean that 100 volumes of the test liquors contain the same amount of absolute alcohol as 80 and 120 volumes of proof spirit respectively. Proof spirit is defined in the United States as a mixture of alcohol and water which contains equal volumes of alcohol and water at 60° F., the alcohol having a specific gravity of 0·7939 at 60° as compared with water at its maximum density. The specific gravity of proof spirit is 0·93353 at 60°; and 100 volumes of the mixture is made from 50 volumes of absolute alcohol and 53·71 volumes of water.

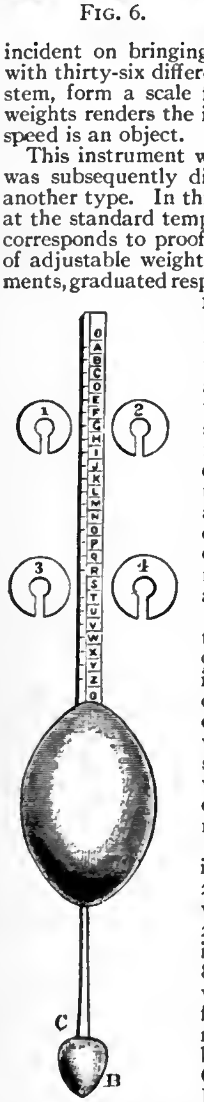

FIG. 7.—Atkins's Hydrometer.

Quin's universal hydrometer is described in the *Transactions of the Society of Arts*, viii. 98. It is provided with a sliding rule to adapt it to different temperatures, and has four scales, one of which is graduated for spirits and the other three serve to show the strengths of worts. The peculiarity of the instrument consists in the pyramidal form given to the stem, which renders the scale-divisions more nearly equal in length than they would be on a prismatic stem.

Atkins's hydrometer, as originally constructed, is described in *Nicholson's Journal*, 8vo, ii. 276. It is made of brass, and is provided with a spheroidal bulb the axis of which is 2 in. in length, the conjugate diameter being 1½ in. The whole length of the instrument is 8 in., the stem square of about ⅛-in. side, and the weight about 400 grains. It is provided with four weights, marked 1, 2, 3, 4, and weighing respectively 20, 40, 61 and 84 grains, which can be attached to the shank of the instrument at C (fig. 7) and retained there by the fixed weight B. The scale engraved upon one face of the stem contains fifty-five divisions, the top and bottom being marked 0 or zero and the alternate intermediate divisions (of which there are twenty-six) being marked with the letters of the alphabet in order. The four weights are so adjusted that, if the instrument floats with the stem emerging as far as the lower division 0 with one of the weights attached, then replacing the weight by the next heavier causes the instrument to sink through the whole length of the scale to the upper division 0, and the first weight produces the same effect when applied to the naked instrument. The stem is thus virtually extended to five times its length, and the number of divisions increased practically to 272. When no weight is attached the instrument indicates densities from ·806 to ·843; with No. 1 it registers from ·843 to ·880, with No. 2 from ·880 to ·918, with No. 3 from ·918 to ·958, and with No. 4 from ·958 to 1·000, the temperature being 55° F. It will thus be seen that the whole length of the stem corresponds to a difference of density of about ·04, and one division to about ·00074, indicating a difference of little more than ⅛% in the strength of any sample of spirits.

The instrument is provided with a sliding rule, with scales corresponding to the several weights, which indicate the specific gravity corresponding to the several divisions of the hydrometer scale compared with water at 55° F. The slider upon the rule serves to adjust the scale for different temperatures, and then indicates the strength of the spirit in percentages over or under proof. The slider is also provided with scales, marked respectively Dicas and Clarke, which serve to show the readings which would have been obtained had the instruments of those makers been employed. The line on the scale marked "concentration" indicates the diminution in volume consequent upon reducing the sample to proof strength (if it is *over proof*, O.P.) or upon reducing proof spirit to the strength of the sample (if it is *under proof*, U.P.). By applying the several weights in succession in addition to No. 4 the instrument can be employed for liquids heavier than water; and graduations on the other three sides of the stem, together with an additional slide rule, adapt the instrument for the determination of the strength of worts.

Atkins subsequently modified the instrument (*Nicholson's Journal*, 8vo, iii. 50) by constructing the different weights of different shapes, viz. circular, square, triangular and pentagonal, instead of numbering them 1, 2, 3 and 4 respectively, a figure of the weight being stamped on the sliding rule opposite to every letter in the series to which it belongs, thus diminishing the probability of mistakes. He also replaced the letters on the stem by the corresponding specific gravities referred to water as unity. Further information concerning these instruments and the state of hydrometry in 1803 will be found in Atkins's pamphlet *On the Relation between the Specific Gravities and the Strength of Spirituous Liquors* (1803); or *Phil. Mag.* xvi. 26-33, 205-212, 305-312; xvii. 204-210 and 329-341.

In Gay-Lussac's alcoholometer the scale is divided into 100 parts corresponding to the presence of 1, 2, ... % by volume of alcohol at 15° C., the highest division of the scale corresponding to the purest alcohol he could obtain (density ·7947) and the lowest division corresponding to pure water. A table provides the necessary corrections for other temperatures.

Tralles's hydrometer differs from Gay-Lussac's only in being graduated at 4° C. instead of 15° C., and taking alcohol of density ·7939 at 15·5° C. for pure alcohol instead of ·7947 as taken by Gay-Lussac (Keene's *Handbook of Hydrometry*).

In Beck's hydrometer the zero of the scale corresponds to density 1·000 and the division 30 to density ·850, and equal divisions on the scale are continued as far as is required in both directions.

In the centesimal hydrometer of Francœur the volume of the stem between successive divisions of the scale is always $\frac{1}{100}$th of the whole volume immersed when the instrument floats in water at 4° C. In order to graduate the stem the instrument is first weighed, then immersed in distilled water at 4° C., and the line of flotation marked zero. The first degree is then found by placing on the top of the stem a weight equal to $\frac{1}{100}$th of the weight of the instrument, which increases the volume immersed by $\frac{1}{100}$th of the original volume. The addition to the top of the stem of successive weights, each $\frac{1}{100}$th of the weight of the instrument itself, serves to determine the successive degrees. The length of 100 divisions of the scale, or the length of the uniform stem the volume of which would be equal to that of the hydrometer up to the zero graduation, Francœur called the "modulus" of the hydrometer. He constructed his instruments of glass, using different instruments for different portions of the scale (Francœur, *Traité d'aréométrie*, Paris, 1842).

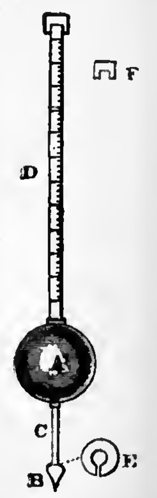

FIG. 8.—Sikes's Hydrometer.

Dr Boriés of Montpellier constructed a hydrometer which was based upon the results of his experiments on mixtures of alcohol and water. The interval between the points corresponding to pure alcohol and to pure water Boriés divided into 100 equal parts, though the stem was prolonged so as to contain only 10 of these divisions, the other 90 being provided for by the addition of 9 weights to the bottom of the instrument as in Clarke's hydrometer.

The instrument which has now been exclusively used for revenue purposes for nearly a century is that associated with the name of Bartholomew Sikes, who was correspondent to the Board of Excise from 1774 to 1783, and for some time collector of excise for Hertfordshire.

Sikes's hydrometer, on account of its similarity to that of Boriés, appears to have been borrowed from that instrument. It is made of gilded brass or silver, and consists of a spherical ball A (fig. 8), 1·5 in. in diameter, below which is a weight B connected with the ball by a short conical stem C. The stem D is rectangular in section and about 3½ in. in length. This is divided into ten equal parts, each of which is subdivided into five. As in Boriés's instrument, a series of 9 weights, each of the form shown at E, serves to extend the scale to 100 principal divisions. In the centre of each weight is a hole capable of admitting the lowest and thickest end of the conical stem C, and a slot is cut into it just wide enough to allow the upper part of the cone to pass. Each weight can thus be dropped on to the lower stem so as to rest on the counterpoise B. The weights are marked 10, 20, . . . 90; and in using the instrument that weight must be selected which will allow it to float in the liquid with a portion only of the stem submerged. Then the reading of the scale at the line of flotation, added to the number on the weight, gives the reading required. A small supernumerary weight F is added, which can be placed upon the top of the stem. F is so adjusted that when the 60 weight is placed on the lower stem the instrument sinks to the same point in distilled water when F is attached as in proof spirit when F is removed. The best instruments are now constructed for revenue purposes of silver, heavily gilded, because it was found that saccharic acid contained in some spirits attacked brass behind the gilding.

The following table gives the specific gravities corresponding to the principal graduations on Sikes's hydrometer at 60° F. and 62° F., together with the corresponding strengths of spirits. The latter are based upon the tables of Charles Gilpin, clerk to the Royal Society, for which the reader is referred to the *Phil. Trans.* for 1794. Gilpin's work is a model for its accuracy and thoroughness of detail, and his results have scarcely been improved upon by more recent workers. The merit of Sikes's system lies not so much in the hydrometer as in the complete system of tables by which the readings of the instrument are at once converted into percentage of proof-spirit.

Table showing the Densities corresponding to the Indications of Sikes's Hydrometer.

In the above table for Sikes's hydrometer two densities are given corresponding to each of the degrees 20, 30, 40, 50, 60, 70, 80 and 90, indicating that the successive weights belonging to the particular instrument for which the table has been calculated do not quite agree. The discrepancy, however, does not produce any sensible error in the strength of the corresponding spirit.

A table which indicates the weight per gallon of spirituous liquors for every degree of Sikes's hydrometer is printed in 23 and 24 Vict. c. 114, schedule B. This table differs slightly from that given above, which has been abridged from the table given in Keene's *Handbook of Hydrometry*, apparently on account of the equal divisions on Sikes's scale having been taken as corresponding to equal increments of density.

Sikes's hydrometer was established for the purpose of collecting the revenue of the United Kingdom by Act of Parliament, 56 Geo. III. c. 140, by which it was enacted that "all spirits shall be deemed and taken to be of the degree of strength which the said hydrometers called Sikes's hydrometers shall, upon trial by any officer or officers of the customs or excise, denote such spirits to be." This act came into force on January 5, 1817, and was to have remained in force until August 1, 1818, but was repealed by 58 Geo. III. c. 28, which established Sikes's hydrometer on a permanent footing. By 3 and 4 Will. IV. c. 52, § 123, it was further enacted that the same instruments and methods should be employed in determining the duty upon imported spirits as should in virtue of any Act of Parliament be employed in the determination of the duty upon spirits distilled at home. It is the practice of the officers of the inland revenue to adjust Sikes's hydrometer at 62° F., that being the temperature at which the imperial gallon is defined as containing 10 ℔ avoirdupois of distilled water. The specific gravity of any sample of spirits thus determined, when multiplied by ten, gives the weight in pounds per Imperial gallon, and the weight of any bulk of spirits divided by this number gives its volume at once in imperial gallons.

Mr (afterwards Colonel) J. B. Keene, of the Hydrometer Office, London, has constructed an instrument after the model of Sikes's, but provided with twelve weights of different masses but equal volumes, and the instrument is never used without having one of these attached. When loaded with either of the lightest two weights the instrument is specifically lighter than Sikes's hydrometer when unloaded, and it may thus be used for specific gravities as low as that of absolute alcohol. The volume of each weight being the same, the whole volume immersed is always the same when it floats at the same mark whatever weight may be attached.

Besides the above, many hydrometers have been employed for special purposes. Twaddell's hydrometer is adapted for densities greater than that of water. The scale is so arranged that the reading multiplied by 5 and added to 1000 gives the specific gravity with reference to water as 1000. To avoid an inconveniently long stem, different instruments are employed for different parts of the scale as mentioned above.

The lactometer constructed by Dicas of Liverpool is adapted for the determination of the quality of milk. It resembles Sikes's hydrometer in other respects, but is provided with eight weights. It is also provided with a thermometer and slide rule, to reduce the readings to the standard temperature of 55° F. Any determination of density can be taken only as affording prima facie evidence of the quality of milk, as the removal of cream and the addition of water are operations which tend to compensate each other in their influence on the density of the liquid, so that the lactometer cannot be regarded as a reliable instrument.

The marine hydrometers, as supplied by the British government to the royal navy and the merchant marine, are glass instruments with slender stems, and generally serve to indicate specific gravities from 1·000 to 1·040. Before being issued they are compared with a standard instrument, and their errors determined. They are employed for taking observations of the density of sea-water.

The salinometer is a hydrometer originally intended to indicate the strength of the brine in marine boilers in which sea-water is employed. Saunders's salinometer consists of a hydrometer which floats in a chamber through which the water from the boiler is allowed to flow in a gentle stream, at a temperature of 200° F. The peculiarity of the instrument consists in the stream of water, as it enters the hydrometer chamber, being made to impinge against a disk of metal, by which it is broken into drops, thus liberating the steam, which would otherwise disturb the instrument.

The use of Sikes's hydrometer necessitates the employment of a considerable quantity of spirit. For the testing of spirits in bulk no more convenient instrument has been devised, but where very small quantities are available more suitable laboratory methods must be adopted.

In England, the Finance Act 1907 (7 Ed. VII. c. 13), section 4, provides as follows: (1) The Commissioners of Customs and the Commissioners of Inland Revenue may jointly make regulations authorizing the use of any means described in the regulations for ascertaining for any purpose the strength or weight of spirits. (2) Where under any enactment Sykes's (*sic*) Hydrometer is directed to be used or may be used for the purpose of ascertaining the strength or weight of spirits, any means so authorized by regulations may be used instead of Sykes's Hydrometer and references to Sykes's Hydrometer in any enactment shall be construed accordingly. (3) Any regulations made under this section shall be published in the London, Edinburgh and Dublin Gazette, and shall take effect from the date of publication, or such later date as may be mentioned in the regulations for the purpose. (4) The expression "spirits" in this section has the same meaning as in the Spirits Act 1880. (W. G.)

HYDROPATHY, the name given, from the Greek, to the "water-cure," or the treatment of disease by water, used outwardly and inwardly. Like many descriptive names, the word "hydropathy" is defective and even misleading, the active agents in the treatment being heat and cold, of which water is little more than the vehicle, and not the only one. Thermotherapeutics (or thermotherapy) is a term less open to objection.

Hydropathy, as a formal system, dates from about 1829, when Vincenz Priessnitz (1801–1851), a farmer of Gräfenberg in Silesia, Austria, began his public career in the paternal homestead, extended so as to accommodate the increasing numbers attracted by the fame of his cures. Two English works, however, on the medical uses of water had been translated into German in the century preceding the rise of the movement under Priessnitz. One of these was by Sir John Floyer (1649–1734), a physician of Lichfield, who, struck by the remedial use of certain springs by the neighbouring peasantry, investigated the history of cold bathing, and published in 1702 his "*Ψυχρολουσία, or the History of Cold Bathing, both Ancient and Modern.*" The book ran through six editions within a few years, and the translation was largely drawn upon by Dr J. S. Hahn of Silesia, in a work published in 1738, *On the Healing Virtues of Cold Water, Inwardly and Outwardly applied, as proved by Experience.* The other work was that of Dr James Currie (1756–1805) of Liverpool, entitled *Medical Reports on the Effects of Water, Cold and Warm, as a remedy in Fevers and other Diseases*, published in 1797, and soon after translated into German by Michaelis (1801) and Hegewisch (1807). It was highly popular, and first placed the subject on a scientific basis. Hahn's writings had meanwhile created much enthusiasm among his countrymen, societies having been everywhere formed to promote the medicinal and dietetic use of water; and in 1804 Professor Örtel of Ansbach republished them and quickened the popular movement by unqualified commendation of water drinking as a remedy for all diseases. In him the rising Priessnitz found a zealous advocate, and doubtless an instructor also.

At Gräfenberg, to which the fame of Priessnitz drew people of every rank and many countries, medical men were conspicuous by their numbers, some being attracted by curiosity, others by the desire of knowledge, but the majority by the hope of cure for ailments which had as yet proved incurable. Many records of experiences at Gräfenberg were published, all more or less favourable to the claims of Priessnitz, and some enthusiastic in their estimate of his genius and penetration; Captain Claridge introduced hydropathy into England in 1840, his writings and lectures, and later those of Sir W. Erasmus Wilson (1809–1884), James Manby Gully (1808–1883) and Edward Johnson, making numerous converts, and filling the establishments opened soon after at Malvern and elsewhere. In Germany, France and America hydropathic establishments multiplied with great rapidity. Antagonism ran high between the old practice and the new. Unsparing condemnation was heaped by each on the other; and a legal prosecution, leading to a royal commission of inquiry, served but to make Priessnitz and his system stand higher in public estimation.

Increasing popularity diminished before long that timidity which had in great measure prevented trial of the new method from being made on the weaker and more serious class of cases, and had caused hydropathists to occupy themselves mainly with a sturdy order of chronic invalids well able to bear a rigorous regimen and the severities of unrestricted crisis. The need of a radical adaptation to the former class was first adequately recognized by John Smedley, a manufacturer of Derbyshire, who, impressed in his own person with the severities as well as the benefits of "the cold water cure," practised among his workpeople a milder form of hydropathy, and began about 1852 a new era in its history, founding at Matlock a counterpart of the establishment at Gräfenberg.

Ernst Brand (1826–1897) of Berlin, Räljen and Theodor von Jürgensen of Kiel, and Karl Liebermeister (1833–1901) of Basel, between 1860 and 1870, employed the cooling bath in abdominal typhus with striking results, and led to its introduction to England by Dr Wilson Fox. In the Franco-German war the cooling bath was largely employed, in conjunction frequently with quinine; and it now holds a recognized position in the treatment of hyperpyrexia. The wet sheet pack has become part of medical practice; the Turkish bath, introduced by David Urquhart (1805–1877) into England on his return from the East, and ardently adopted by Dr Richard Barter (1802–1870) of Cork, has become a public institution, and, with the "morning tub" and the general practice of water drinking, is the most noteworthy of the many contributions by hydropathy to public health (see BATHS, *ad fin.*).

The appliances and arrangements by means of which heat and cold are brought to bear on the economy are—(*a*) Packings, hot and cold, general and local, sweating and cooling; (*b*) hot air and steam baths; (*c*) general baths, of hot water and cold; (*d*) sitz, spinal, head and foot baths; (*e*) bandages (or compresses), wet and dry; also (*f*) fomentations and poultices, hot and cold, sinapisms, stupes, rubbings and water potations, hot and cold.

(*a*) Packings.—The full pack consists of a wet sheet enveloping the body, with a number of dry blankets packed tightly over it, including a macintosh covering or not. In an hour or less these are removed and a general bath administered. The pack is a derivative, sedative, sudorific and stimulator of cutaneous excretion. There are numerous modifications of it, notably the cooling pack, where the wrappings are loose and scanty, permitting evaporation, and the application of indefinite duration, the sheet being rewetted as it dries; this is of great value in protracted febrile conditions. There are also local packs, to trunk, limbs or head separately, which are derivative, soothing or stimulating, according to circumstance and detail.

(*b*) Hot air baths, the chief of which is the Turkish (properly, the Roman) bath, consisting of two or more chambers ranging in temperature from 120° to 212° or higher, but mainly used at 150° for curative purposes. Exposure is from twenty minutes up to two hours according to the effect sought, and is followed by a general bath, and occasionally by soaping and shampooing. It is stimulating, derivative, depurative, sudorific and alterative, powerfully promoting tissue change by increase of the natural waste and repair. It determines the blood to the surface, reducing internal congestions, is a potent diaphoretic, and, through the extremes of heat and cold, is an effective nervous and vascular stimulant and tonic. Morbid growths and secretions, as also the uraemic, gouty and rheumatic diathesis, are beneficially influenced by it. The full pack and Turkish bath have between them usurped the place and bettered the function of the once familiar hot bath. The Russian or steam bath and the lamp bath are primitive and inferior varieties of the modern Turkish bath, the atmosphere of which cannot be too dry and pure.

(*c*) General baths comprise the rain (or needle), spray (or rose), shower, shallow, plunge, douche, wave and common morning sponge baths, with the dripping sheet, and hot and cold spongings, and are combinations, as a rule, of hot and cold water. They are stimulating, tonic, derivative and detergent.

(*d*) Local baths comprise the sitz (or sitting), douche (or spouting), spinal, foot and head baths, of hot or cold water, singly or in combination, successive or alternate. The sitz, head and foot baths are used "flowing" on occasion. The application of cold by "Leiter's tubes" is effective for reducing inflammation (*e.g.* in meningitis and in sunstroke); in these a network of metal or indiarubber tubing is fitted to the part affected, and cold water kept continuously flowing through them. Rapid alternations of hot and cold water have a powerful effect in vascular stasis and lethargy of the nervous system and absorbents, yielding valuable results in local congestions and chronic inflammations.

(*e*) Bandages (or compresses) are of two kinds,—*cooling*, of wet material left exposed for evaporation, used in local inflammations and fevers; and *heating*, of the same, covered with waterproof material, used in congestion, external or internal, for short or long periods. Poultices, warm, of bread, linseed, bran, &c., changed but twice in twenty-four hours, are identical in action with the heating bandage, and superior only in the greater warmth and consequent vital activity their closer application to the skin ensures.

(*f*) Fomentations and poultices, hot or cold, sinapisms, stupes, rubefacients, irritants, frictions, kneadings, calisthenics, gymnastics, electricity, &c., are adjuncts largely employed.

BIBLIOGRAPHY.—Among the numerous earlier works on hydropathy, the following are worth mention: Balbirnie, *Water Cure in Consumption* (1847), *Hydropathic Aphorisms* (1856) and *A Plea for the Turkish Bath* (1862); Beni-Barde, *Traité d'hydrothérapie* (1874); Claridge, *Cold Water Cure, or Hydropathy* (1841), *Facts and Evidence in Support of Hydropathy* (1843) and *Cold Water, Tepid Water and Friction Cure* (1849); Dunlop, *Philosophy of the Bath* (1873); Floyer, *Psychrolousia, or the History of Cold-Bathing*, &c. (1702); J. S. Hahn (Schweidnitz), *Observations on the Healing Virtues of Cold Water* (1738); Hunter, *Hydropathy for Home Use* (1879); E. W. Lane, *Hydropathy, or the Natural System of Medical Treatment* (1857); R. J. Lane, *Life at the Water Cure* (1851); Shew, *Hydropathic Family Physician* (1857); Smedley, *Practical Hydropathy* (1879); Smethurst, *Hydrotherapia, or the Water Cure* (1843); Wainwright, *Inquiry into the Nature and Use of Baths* (1737); Weiss, *Handbook of Hydropathy* (1844); Wilson *Principles and Practice of the Cold Water Cure* (1854) and *The Water Cure* (1859). A useful recent work dealing comprehensively with the subject is Richard Metcalfe's *Rise and Progress of Hydropathy* (1906).

HYDROPHOBIA (Gr. ὕδωρ, water, and φόβος, fear; so called from the symptom of dread of water), or RABIES (Lat. for "madness"), an acute disease, occurring chiefly in certain of the lower animals, particularly the canine species, and liable to be communicated by them to other animals and to man.

In Dogs, &c.—The occurrence of rabies in the fox, wolf, hyaena, jackal, raccoon, badger and skunk has been asserted; but there is every probability that it is originally a disease of the dog. It is communicated by inoculation to nearly all, if not all, warm-blooded creatures. The transmission from one animal to another only certainly takes place through inoculation with viruliferous matters. The malady is generally characterized at a certain stage by an irrepressible desire in the animal to act offensively with its natural weapons—dogs and other carnivora attacking with their teeth, herbivora with their hoofs or horns, and birds with their beaks, when excited ever so slightly. In the absence of excitement the malady may run its course without any fit of fury or madness.

Symptoms.—The disease has been divided into three stages or periods, and has also been described as appearing in at least two forms, according to the peculiarities of the symptoms. But, as a rule, one period of the disease does not pass suddenly into another, the transition being almost imperceptible; and the forms do not differ essentially from each other, but appear merely to constitute varieties of the same disease, due to the natural disposition of the animal, or other modifying circumstances. These forms have been designated *true* or *furious rabies* (Fr. *rage vrai*; Ger. *rasende Wuth*) and *dumb rabies* (Fr. *rage mue*; Ger. *stille Wuth*).

The malady does not commence with fury and madness, but in a strange and anomalous change in the habits of the dog: it becomes dull, gloomy, and taciturn, and seeks to isolate itself in out-of-the-way places, retiring beneath chairs and to odd corners. But in its retirement it cannot rest: it is uneasy and fidgety, and no sooner has it lain down than suddenly it jumps up in an agitated manner, walks backwards and forwards several times, again lies down and assumes a sleeping attitude, but has only maintained it for a few minutes when it is once more moving about. Again it retires to its corner, to the farthest recess it can find, and huddles itself up into a heap, with its head concealed beneath its chest and fore-paws. This state of continual agitation and inquietude is in striking contrast with its ordinary habits, and should therefore receive attention. Not unfrequently there are a few moments when the creature appears more lively than usual, and displays an extraordinary amount of affection. Sometimes there is a disposition to gather up straw, thread, bits of wood, &c., which are industriously carried away; a tendency to lick anything cold, as iron, stones, &c., is also observed in many instances; and there is also a desire evinced to lick other animals. Sexual excitement is also frequently an early symptom. At this period no disposition to bite is observed; the animal is docile with its master and obeys his voice, though not so readily as before, nor with the same pleased countenance. There is something strange in the expression of its face, and the voice of its owner is scarcely able to make it change from a sudden gloominess to its usual animated aspect. These symptoms gradually become more marked; the restlessness and agitation increase. If on straw the dog scatters and pulls it about with its paws, and if in a room it scratches and tumbles the cushions or rugs on which it usually lies. It is incessantly on the move, rambling about, scratching the ground, sniffing in corners and at the doors, as if on the scent or seeking for something. It indulges in strange movements, as if affected by some mental influences or a prey to hallucinations. When not excited by any external influence it will remain for a brief period perfectly still and attentive, as if watching something, or following the movements of some creature on the wall; then it will suddenly dart forward and snap at the vacant air, as if pursuing an annoying object, or endeavouring to seize a fly. At another time it throws itself, yelling and furious, against the wall, as if it heard threatening voices on the other side, or was bent on attacking an enemy. Nevertheless, the animal is still docile and submissive, for its master's voice will bring it out of its frenzy. But the saliva is already virulent, and the excessive affection which it evinces at intervals, by licking the hands or face of those it loves, renders the danger very great should there be a wound or abrasion. Until a late period in the disease the master's voice has a powerful influence over the animal. When it has escaped from all control and wanders erratically abroad, ferocious and restless, and haunted by horrid phantoms, the familiar voice yet exerts its influence, and it is rare indeed that it attacks its master.

There is no dread of water in the rabid dog; the animal is generally thirsty, and if water be offered will lap it with avidity, and swallow it at the commencement of the disease. And when, at a later period, the constriction about the throat—symptomatic of the disease—renders swallowing difficult, the dog will none the less endeavour to drink, and the lappings are as frequent and prolonged when deglutition becomes impossible. So little dread has the rabid dog of water that it will ford streams and swim rivers; and when in the ferocious stage it will even do this in order to attack other creatures on the opposite side.

At the commencement of the disease the dog does not usually refuse to eat, and some animals are voracious to an unusual degree. But in a short time it becomes fastidious, only eating what it usually has a special predilection for. Soon, however, this gives place to a most characteristic symptom—either the taste becomes extremely depraved or the dog has a fatal and imperious desire to bite and ingest everything. The litter of its kennel, wool from cushions, carpets, stockings, slippers, wood, grass, earth, stones, glass, horse-dung, even its own faeces and urine, or whatever else may come in its way, are devoured. On examination of the body of a dog which has died of rabies it is so common to find in the stomach a quantity of dissimilar and strange matters on which the teeth have been exercised that, if there was nothing known of the animal's history, there would be strong evidence of its having been affected with the disease. When a dog, then, is observed to gnaw and eat suchlike matters, though it exhibits no tendency to bite, it should be suspected.

The mad dog does not usually foam at the mouth to any great extent at first. The mucus of the mouth is not much increased in quantity, but it soon becomes thicker, viscid, and glutinous, and adheres to the angles of the mouth, fauces and teeth. It is at this period that the thirst is most ardent, and the dog sometimes furiously attempts to detach the saliva with its paws; and if after a while it loses its balance in these attempts and tumbles over, there can no longer be any doubt as to the nature of the malady. There is another symptom connected with the mouth in that form of the disease named "dumb madness" which has frequently proved deceptive. The lower jaw drops in consequence of paralysis of its muscles, and the mouth remains open. The interior is dry from the air passing continually over it, and assumes a deep red tint, somewhat masked by patches of dust or earth, which more especially adhere to the upper surface of the tongue and to the lips. The strange alteration produced in the dog's physiognomy by its constantly open mouth and the dark colour of the interior is rendered still more characteristic by the dull, sad, or dead expression of the animal's eyes. In this condition the creature is not very dangerous, because generally it could not bite if it tried—indeed there does not appear to be much desire to bite in dumb madness; but the saliva is none the less virulent, and accidental inoculations with it, through imprudent handling, will prove as fatal as in the furious form. The mouth should not be touched,—numerous deaths having occurred through people thinking the dog had some foreign substance lodged in its throat, and thrusting their fingers down to remove it. The sensation of tightness which seems to exist at the throat causes the dog to act as if a bone were fixed between its teeth or towards the back of its mouth, and to employ its fore-paws as if to dislodge it. This is a very deceptive symptom, and may prove equally dangerous if caution be not observed. Vomiting of blood or a chocolate-coloured fluid is witnessed in some cases, and has been supposed to be due to the foreign substances in the stomach, which abrade the lining membrane; this, however, is not correct, as it has been observed in man.

The voice of the rabid dog is very peculiar, and so characteristic that to those acquainted with it nothing more is needed to prove the presence of the disease. Those who have heard it once or twice never forget its signification. Owing to the alterations taking place in the larynx the voice becomes hoarse, cracked and stridulous, like that of a child affected with croup—the "voix du coq," as the French have it. A preliminary bark is made in a somewhat elevated tone and with open mouth; this is immediately succeeded by five, six or eight decreasing howls, emitted when the animal is sitting or standing, and always with the nose elevated, which seem to come from the depths of the throat, the jaws not coming together and closing the mouth during such emission, as in the healthy bark. This alteration in the voice is frequently the first observable indication of the malady, and should at once attract attention. In dumb madness the voice is frequently lost from the very commencement—hence the designation.

The sensibility of the mad dog appears to be considerably diminished, and the animal appears to have lost the faculty of expressing the sensations it experiences: it is mute under the infliction of pain, though there can be no doubt that it still has peripheral sensation to some extent. Burning, beating and wounding produce much less effect than in health, and the animal will even mutilate itself with its teeth. Suspicion, therefore, should always strongly attach to a dog which does not manifest a certain susceptibility to painful impressions and receives punishment without any cry or complaint. There is also reason for apprehension when a dog bites itself persistently in any part of its body. A rabid dog is usually stirred to fury at the sight of one of its own species; this test has been resorted to by Henrie Marie Bouley (1814–1885) to dissipate doubts as to the existence of the disease when the diagnosis is otherwise uncertain. As soon as the suspected animal, if it is really rabid, finds itself in the presence of another of its species it at once assumes the aggressive, and, if allowed, will bite furiously. All rabid animals indeed become excited, exasperated, and furious at the sight of a dog, and attack it with their natural weapons, even the timid sheep when rabid butts furiously at the enemy before which in health it would have fled in terror. This inversion of sentiment is sometimes valuable in diagnosing the malady; it is so common that it may be said to be present in every case of rabies. When, therefore, a dog, contrary to its habits and natural inclination, becomes suddenly aggressive to other dogs, it is time to take precautions.

In the large majority of instances the dog is inoffensive in the early period of the disease to those to whom it is familiar. It then flies from its home and either dies, is killed as "mad," or returns in a miserable plight, and in an advanced stage of the malady, when the desire to bite is irresistible. It is in the early stage that sequestration and suppressive measures are most valuable. The dogs which propagate the disease are usually those that have escaped from their owners. After two or three days, frequently in about twelve hours, more serious and alarming symptoms appear, ferocious instincts are developed, and the desire to do injury is irrepressible. The animal has an indefinable expression of sombre melancholy and cruelty. The eyes have their pupils dilated, and emit flashes of light when they are not dull and heavy; they always appear so fierce as to produce terror in the beholder; they are red, and their sensibility to light is increased; and wrinkles, which sometimes appear on the forehead, add to the repulsive aspect of the animal. If caged it flies at the spectator, emitting its characteristic howl or bark, and seizing the iron bars with its teeth, and if a stick be thrust before it this is grasped and gnawed. This fury is soon succeeded by lassitude, when the animal remains insensible to every excitement. Then all at once it rouses up again, and another paroxysm of fury commences. The first paroxysm is usually the most intense, and the fits vary in duration from some hours to a day, and even longer; they are ordinarily briefer in trained and pet dogs than in those which are less domesticated, but in all the remission is so complete after the first paroxysm that the animals appear to be almost well, if not in perfect health. During the paroxysms respiration is hurried and laboured, but tranquil during the remissions. There is an increase of temperature, and the pulse is quick and hard. When the animal is kept in a dark place and not excited, the fits of fury are not observed. Sometimes it is agitated and restless in the manner already described. It never becomes really furious or aggressive unless excited by external objects—the most potent of these, as has been said, being another dog, which, however, if it be admitted to its cage, it may not at once attack. The attacked animal rarely retaliates, but usually responds to the bites by acute yells, which contrast strangely with the silent anger of the aggressor, and tries to hide its head with its paws or beneath the straw. These repeated paroxysms hurry the course of the disease. The secretion and flowing of a large quantity of saliva from the mouth are usually only witnessed in cases in which swallowing has become impossible, the mouth being generally dry. At times the tongue, nose and whole head appear swollen. Other dogs frequently shun one which is rabid, as if aware of their danger.

The rabid dog, if lodged in a room or kept in a house, is continually endeavouring to escape; and when it makes its escape it goes freely forward, as if impelled by some irresistible force. It travels considerable distances in a short time, perhaps attacking every living creature it meets—preferring dogs, however, to other animals, and these to mankind; cats, sheep, cattle and horses are particularly liable to be injured. It attacks in silence, and never utters a snarl or a cry of anger; should it chance to be hurt in return it emits no cry or howl of pain. The degree of ferocity appears to be related to natural disposition and training. Some dogs, for instance, will only snap or give a slight bite in passing, while others will bite furiously, tearing the objects presented to them, or which they meet in their way, and sometimes with such violence as to injure their mouth and break their teeth, or even their jaws. If chained, they will in some cases gnaw the chain until their teeth are worn away and the bones laid bare. The rabid dog does not continue its progress very long. Exhausted by fatigue and the paroxysms of madness excited in it by the objects it meets, as well as by hunger, thirst, and also, no doubt, by the malady, its limbs soon become feeble; the rate of travelling is lessened and the walk is unsteady, while its drooping tail, head inclined towards the ground, open mouth, and protruded tongue (of a leaden colour or covered with dust) give the distressed creature a very striking and characteristic physiognomy. In this condition, however, it is much less to be dreaded than in its early fits of fury, since it is no longer capable or desirous of altering its course or going out of its way to attack an animal or a man not immediately in the path. It is very probable that its fast-failing vision, deadened scent, and generally diminished perception prevent its being so readily impressed or excited by surrounding objects as it previously was. To each paroxysm, which is always of short duration, there succeeds a degree of exhaustion as great as the fits have been violent and oft repeated. This compels the animal to stop; then it shelters itself in obscure places—frequently in ditches by the roadside—and lies there in a somnolescent state for perhaps hours. There is great danger, nevertheless, in disturbing the dog at this period; for when roused from its torpor it has sometimes sufficient strength to inflict a bite. This period, which may be termed the second stage, is as variable in its duration as the first, but it rarely exceeds three or four days. The above-described phenomena gradually merge into those of the third or last period, when symptoms of paralysis appear, which are speedily followed by death. During the remission in the paroxysms these paralytic symptoms are more particularly manifested in the hind limbs, which appear as if unable to support the animal's weight, and cause it to stagger about; or the lower jaw becomes more or less drooping, leaving the parched mouth partially open. Emaciation rapidly sets in, and the paroxysms diminish in intensity, while the remissions become less marked. The physiognomy assumes a still more sinister and repulsive aspect; the hair is dull and erect; the flanks are retracted; the eyes lose their lustre and are buried in the orbits, the pupil being dilated, and the cornea dull and semi-opaque; very often, even at an early period, the eyes squint, and this adds still more to the terrifying appearance of the poor dog. The voice, if at all heard, is husky, the breathing laborious, and the pulse hurried and irregular. Gradually the paralysis increases, and the posterior extremities are dragged as if the animal's back were broken, until at length it becomes general; it is then the prelude to death. Or the dog remains lying in a state of stupor, and can only raise itself with difficulty on the fore-limbs when greatly excited. In this condition it may yet endeavour to bite at objects within its reach. At times convulsions of a tetanic character appear in certain muscles; at other times these are general. A comatose condition ensues, and the rabid dog, if permitted to die naturally, perishes, in the great majority of cases, from paralysis and asphyxia.

In dumb madness there is paralysis of the lower jaw, which imparts a curious and very characteristic physiognomy to the dog; the voice is also lost, and the animal can neither eat nor drink. In this condition the creature remains with its jaw pendent and the mouth consequently wide open, showing the flaccid or swollen tongue covered with brownish matter, and a stringy gelatinous-looking saliva lying between it and the lower lip and coating the fauces, which sometimes appear to be inflamed. Though the animal is unable to swallow fluids, the desire to drink is nevertheless intense; for the creature will thrust its face into the vessel of water in futile attempts to obtain relief, even until the approach of death. Water may be poured down its throat without inducing a paroxysm. The general physiognomy and demeanour of the poor creature inspire the beholder with pity rather than fear. The symptoms due to cerebral excitement are less marked than in the furious form of the disease; the agitation is not so considerable, and the restlessness, tendency to run away, and desire to bite are nearly absent; generally the animal is quite passive. Not unfrequently one or both eyes squint, and it is only when very much excited that the dog may contrive to close its mouth. Sometimes there is swelling about the pharynx and the neck; when the tongue shares in this complication it hangs out of the mouth. In certain cases there is a catarrhal condition of the membrane lining the nasal cavities, larynx, and bronchi; sometimes the animal testifies to the existence of abdominal pain, and the faeces are then soft or fluid. The other symptoms—such as the rapid exhaustion and emaciation, paralysis of the posterior limbs towards the termination of the disease, as well as the rapidity with which it runs its course—are the same as in the furious form.

The simultaneous occurrence of furious and dumb madness has frequently been observed in packs of fox-hounds. Dumb madness differs, then, from the furious type in the paralysis of the lower jaw, which hinders the dog from biting, save in very exceptional circumstances; the ferocious instincts are also in abeyance; and there is no tendency to aggression. It has been calculated that from 15 to 20% of rabid dogs have this particular form of the disease. Puppies and young dogs chiefly have furious rabies.

These are the symptoms of rabies in the dog; but it is not likely, nor is it necessary, that they will all be present in every case. In other species the symptoms differ more or less from those manifested by the dog, but they are generally marked by a change in the manner and habits of the creatures affected, with strong indications of nervous disturbance, in the majority of species amounting to ferociousness and a desire to injure, timid creatures becoming bold and aggressive.

In Human Beings.—The disease of hydrophobia has been known from early times, and is alluded to in the works of Aristotle, Xenophon, Plutarch, Virgil, Horace, Ovid and many others, as well as in those of the early writers on medicine. Celsus gives detailed instructions respecting the treatment of men who have been bitten by rabid dogs, and dwells on the dangers attending such wounds. After recommending suction of the bitten part by means of a dry cupping glass, and thereafter the application of the actual cautery or of strong caustics, and the employment of baths and various internal remedies, he says: "Idque cum ita per triduum factum est, tutus esse homo a periculo videtur. Solet autem ex eo vulnere, ubi parum occursum est, aquae timor nasci, ὑδροφοβίαν Graeci appellant. Miserrimum genus morbi; in quo simul aeger et siti et aquae metu cruciatur; quo oppressis in angusto spes est." Subsequently Galen described minutely the phenomena of hydrophobia, and recommended the excision of the wounded part as a protection against the disease. Throughout many succeeding centuries little or nothing was added to the facts which the early physicians had made known upon the subject. The malady was regarded with universal horror and dread, and the unfortunate sufferers were generally abandoned by all around them and left to their terrible fate. In later times the investigations of Boerhaave, Gerard van Swieten (1700–1772), John Hunter, François Magendie (1783–1855), Gilbert Breschet (1784–1845), Virchow, Albert Reder, as also of William Youatt (1776–1847), George Fleming, Meynell, Karl Hertwig (1798–1881), and others, have furnished important information; but all these were put into the shade by the researches of Pasteur.

The disease is communicated by the secretions of the mouth of the affected animal entering a wound or abrasion of the human skin or mucous membrane. In the great majority of cases (90%) this is due to the bite of a rabid dog, but bites of rabid cats, wolves, foxes, jackals, &c., are occasionally the means of conveying the disease. Numerous popular fallacies still prevail on the subject of hydrophobia. Thus it is supposed that the bite of an angry dog may produce the disease, and all the more if the animal should subsequently develop symptoms of rabies. The ground for this erroneous notion is the fact, which is unquestionable, that animals in whom rabies is in the stage of incubation, during which there are few if any symptoms, may by their bites convey the disease, though fortunately during this early stage they are little disposed to bite. The bite of a non-rabid animal, however enraged, cannot give rise to hydrophobia.

The period of incubation of the disease, or that time which elapses between the introduction of the virus and the development of the symptoms, appears to vary in a remarkable degree, being in some cases as short as a fortnight, and in others as long as several months or even years. On an average it seems to be from about six weeks to three months, but it mainly depends on the part bitten; bites on the head are the most dangerous. The incubation period is also said to be shorter in children. The rare instances of the appearance of hydrophobia many years after the introduction of the poison are always more or less open to question as to subsequent inoculation.

When the disease is about to declare itself it not unfrequently happens that the wound, which had quickly and entirely healed after the bite, begins to exhibit evidence of irritation or inflammatory action, or at least to be the seat of morbid sensations such as numbness, tingling or itching. The symptoms characterizing the premonitory stage are great mental depression and disquietude, together with restlessness and a kind of indefinite fear. There is an unusual tendency to talk, and the articulation is abrupt and rapid. Although in some instances the patients will not acknowledge that they have been previously bitten, and deny it with great obstinacy, yet generally they are well aware of the nature of their malady, and speak despairingly of its consequences. There is in this early stage a certain amount of constitutional disturbance showing itself by feverishness, loss of appetite, sleeplessness, headache, great nervous excitability, respiration of a peculiar sighing or sobbing character, and even occasionally a noticeable aversion to liquids. These symptoms—constituting what is termed the melancholic stage—continue in general for one or two days, when they are succeeded by the stage of excitement in which all the characteristic phenomena of the malady are fully developed. Sometimes the disease first shows itself in this stage, without antecedent symptoms.

The agitation of the sufferer now becomes greatly increased, and the countenance exhibits anxiety and terror. There is noticed a marked embarrassment of the breathing, but the most striking and terrible features of this stage are the effects produced by attempts to swallow fluids. The patient suffers from thirst and desires eagerly to drink, but on making the effort is seized with a most violent suffocative paroxysm produced by spasm of the muscles of swallowing and breathing, which continues for several seconds, and is succeeded by a feeling of intense alarm and distress. With great caution and determination the attempt is renewed, but only to be followed with a repetition of the seizure, until the unhappy sufferer ceases from sheer dread to try to quench the thirst which torments him. Indeed the very thought of doing so suffices to bring on a choking paroxysm, as does also the sound of the running of water. The patient is extremely sensitive to any kind of external impression; a bright light, a loud noise, a breath of cool air, contact with any one, are all apt to bring on one of these seizures. But besides these suffocative attacks there also occur general convulsions affecting the whole muscular system of the body, and occasionally a condition of tetanic spasm. These various paroxysms increase in frequency and severity with the advance of the disease, but alternate with intervals of comparative quiet, in which, however, there is intense anxiety and more or less constant difficulty of breathing, accompanied with a peculiar sonorous expiration, which has suggested the notion that the patient barks like a dog. In many instances there is great mental disturbance, with fits of maniacal excitement, in which he strikes at every one about him, and accuses them of being the cause of his sufferings—these attacks being succeeded by calm intervals in which he expresses great regret for his violent behaviour. During all this stage of the disease the patient is tormented with a viscid secretion accumulating in his mouth, which from dread of swallowing he is constantly spitting about him. There may also be noticed snapping movements of the jaws as if he were attempting to bite, but these are in reality a manifestation of the spasmodic action which affects the muscles generally. There is no great amount of fever, but there is constipation, diminished flow of urine, and often sexual excitement.

After two or three days of suffering of the most terrible description the patient succumbs, death taking place either in a paroxysm of choking, or on the other hand in a tranquil manner from exhaustion, all the symptoms having abated, and the power of swallowing returned before the end. The duration of the disease from the first declaration of the symptoms is generally from three to five days.

Apart from the inoculation method (see below), the treatment of most avail is that which is directed towards preventing the absorption of the poison into the system. This may be accomplished by excision of the part involved in the bite of the rabid animal, or, where this from its locality is impracticable, in the application to the wound of some chemical agent which will destroy the activity of the virus, such as potassa fusa, lunar caustic (nitrate of silver), or the actual cautery in the form of a red-hot wire. The part should be thoroughly acted on by these agents, no matter what amount of temporary suffering this may occasion. Such applications should be resorted to immediately after the bite has been inflicted, or as soon thereafter as possible. Further, even though many hours or days should elapse, these local remedies should still be applied; for if, as appears probable, some at least of the virus remains for long at the injured part, the removal or effectual destruction of this may prevent the dread consequences of its absorption. Every effort should be made to tranquillize and reassure the patient.

Two special points of interest have arisen in recent years in connexion with this disease. One is the Pasteur treatment by inoculation with rabic virus (see also PARASITIC DISEASES), and the other was the attempt of the government to exterminate rabies in the British Isles by muzzling dogs.

Pasteur treatment.

The Pasteur treatment was first applied to human beings in 1885 after prolonged investigation and experimental trial on animals. It is based on the fact that a virus, capable of giving rabies by inoculation, can be extracted from the tissues of a rabid animal and then intensified or attenuated at pleasure. It appears that the strength of the rabic virus, as determined by inoculation, is constant in the same species of animal, but is modified by passing through another species. For instance, the natural virus of dogs is always of the same strength, but when inoculated into monkeys it becomes weakened, and the process of attenuation can be carried on by passing the virus through a succession of monkeys, until it loses the power of causing death. If this weakened virus is then passed back through guinea-pigs, dogs or rabbits, it regains its former strength. Again, if it be passed through a succession of dogs it becomes intensified up to a maximum of strength which is called the *virus fixe*. Pasteur further discovered that the strength can be modified by temperature and by keeping the dried tissues of a rabid animal containing the virus. Thus, if the spinal cord of a rabid dog be preserved in a dry state, the virus loses strength day by day. The system of treatment consists in making an emulsion of the cord and graduating the strength of the dose by using a succession of cords, which have been kept for a progressively diminishing length of time. Those which have been kept for fourteen days are used as a starting-point, yielding virus of a minimum strength. They are followed by preparations of diminishing age and increasing strength, day by day, up to the maximum, which is three days old. These are successively injected into the circulatory system. The principle is the artificial acquisition by the patient of resistance to the rabic virus, which is presumed to be already in the system but has not yet become active, by accustoming him gradually to its toxic effect, beginning with a weak form and progressively increasing the dose. It is not exactly treatment of the disease, because it is useless or nearly so when the disease has commenced, nor is it exactly preventive, for the patient has already been bitten. It must be regarded as a kind of anticipatory cure. The cords are cut into sections and preserved dry in sterilized flasks plugged with cotton-wool. Another method of preparing the inoculatory virus, which has been devised by Guido Tizzoni and Eugenio Centanni, consists in subjecting the *virus fixe* to peptic digestion by diluted gastric juice for varying periods of time.

The first patient was treated by Pasteur's system in July 1885. He was successively inoculated with emulsions made from cords that had been kept fourteen and ten days, then eleven and eight days, then eight, seven, six days, and so on. Two forms of treatment are now used—(1) the "simple," in which the course from weak to strong virus is extended over nine days; (2) the "intensive," in which the maximum is reached in seven days. The latter is used in cases of very bad bites and those of some standing, in which it is desirable to lose no time. Two days are compressed into one at the commencement by making injections morning and evening instead of once a day, so that the fifth-day cord is reached in four days instead of six, as in the "simple" treatment. When the maximum—the third-day cord—is reached the injections are continued with fifth-, fourth-, and third-day cords. The whole course is fifteen days in the simple treatment and twenty-one in the intensive. The doses injected range from 1 to 3 cubic centimetres. Injections are made alternately into the right and left flanks. The following table shows the number treated from 1886 to 1905, with the mortality.

Year.	Patients Treated.	Deaths.	Mortality per cent.
1886	2671	25	·94
1887	1770	14	·79
1888	1622	9	·55
1889	1830	7	·38
1890	1540	5	·32
1891	1559	4	·25
1892	1790	4	·22
1893	1648	6	·36

These figures do not include cases which develop hydrophobia during treatment or within fifteen days after treatment is completed, for it is held that persons who die within that period have their nervous centres invaded by virus before the cure has time to act. The true mortality should therefore be considerably higher. For instance, in 1898 three deaths came within this category, which just doubles the mortality; and in 1899 the additional deaths were six, bringing the mortality up to two-and-a-half times that indicated in the table. When, however, the additional deaths are included the results remain sufficiently striking, if two assumptions are granted—(1) that all the persons treated have been bitten by rabid animals; (2) that a large proportion of persons so bitten usually have hydrophobia. Unfortunately, both these assumptions lack proof, and therefore the evidence of the efficacy of the treatment cannot be said to satisfy a strictly scientific standard. With regard to the first point, the patients are divided into three categories—(1) those bitten by an animal the rabidity of which is proved by the development of rabies in other animals bitten by it or inoculated from its spinal cord; (2) those bitten by an animal pronounced rabid on a veterinary examination; (3) those bitten by an animal suspected of being rabid. The number of patients in each category in 1898 was (1) 141, (2) 855, (3) 469; and in 1899 it was (1) 152, (2) 1099, (3) 363. As might be expected, the vast majority came under the second and third heads, in which the evidence of rabidity is doubtful or altogether lacking. With regard to the second point, the proportion of persons bitten by rabid animals who ordinarily develop hydrophobia has only been "estimated" from very inadequate data. Otto Bollinger from a series of collected statistics states that before the introduction of the Pasteur treatment, of patients bitten by dogs undoubtedly rabid 47% died, the rate being 33% in those whose wounds had been cauterized and 83% when there had been no local treatment. If the number of rabid dogs be compared with the deaths from hydrophobia in any year or series of years, it can hardly be very high. For instance, in 1895, 668 dogs, besides other animals, were killed and certified to be rabid in England, and the deaths from hydrophobia were twenty. Of course this proves nothing, as the number of persons bitten is not known, but the difference between the amount of rabies and of hydrophobia is suggestively great in view of the marked propensity of rabid dogs to bite, nor is it accounted for by the fact that some of the persons bitten were treated at the Institut Pasteur. A comparison of the annual mortality from hydrophobia in France before and after the introduction of the treatment would afford decisive evidence as to its efficacy; but unfortunately no such comparison can be made for lack of vital statistics in that country. The experience of the Paris hospitals, however, points to a decided diminution of mortality. On the whole it must be said, in the absence of further data, that the Pasteur treatment certainly diminishes the danger of hydrophobia from the bites of rabid animals.

More recently treatment with an anti-rabic serum has been suggested (see PARASITIC DISEASES). Victor Babes and Lepp and later Guido Tizzoni and Eugenio Centanni have worked out a method of serum treatment curative and protective. In this method not the rabic poison itself, as in the Pasteur treatment, but the protective substance formed is injected into the tissues. The serum of a vaccinated animal is capable of neutralizing the power of the virus of rabies not only when mixed with the virus before injection but even when injected simultaneously or within twenty-four hours after the introduction of the virus. These authors showed that the serum of a rabbit protects a rabbit better than does the serum of a dog, and vice versa. At the end of twenty days' injections they found they could obtain such a large quantity of anti-rabic substance in the serum of an animal, that even 1 part of serum to 25,000 of the body weight would protect an animal. This process differs from that of Pasteur in so far as that in place of promoting the formation of the antidote within the body of the patient, by a process of vaccination with progressively stronger and stronger virus, this part of the process is carried on in an animal, Babes using the dog and Centanni the sheep, the blood serum of which is injected. This method of vaccination is useful as a protective to those in charge of kennels.

The attempt to stamp out rabies in Great Britain was an experiment undertaken by the government in the public interest.

Muzzling order in England. The principal means adopted were the muzzling of dogs in infected areas, and prolonged quarantine for imported animals. The efficacy of dog-muzzling in checking the spread of rabies and diminishing its prevalence has been repeatedly proved in various countries. Liable as other animals may be to the disease, in England at least the dog is pre-eminently the vehicle of contagion and the great source of danger to human beings. There is a difference of opinion on the way in which muzzling acts, though there can be none as to the effect it produces in reducing rabies. Probably it acts rather by securing the destruction of ownerless and stray—which generally includes rabid—dogs than by preventing biting; for though it may prevent snapping, even the wire-cage muzzle does not prevent furious dogs from biting, and it is healthy, not rabid, dogs that wear the muzzle. It has therefore been suggested that a collar would have the same effect, if all collarless dogs were seized; but the evidence goes to show that it has not, perhaps because rabid dogs are more likely to stray from home with their collars, which are constantly worn, than with muzzles which are not, and so escape seizure. Moreover, it is much easier for the police to see whether a dog is wearing a muzzle or not than it is to make sure about the collar. However this may be, the muzzle has proved more efficacious, but it was not applied systematically in England until a late date. Sometimes the regulations were in the hands of the government, and sometimes they were left to local authorities; in either case they were allowed to lapse as soon as rabies had died down. In April 1897 the Board of Agriculture entered on a systematic attempt to exterminate rabies by the means indicated. The plan was to enforce muzzling over large areas in which the disease existed, and to maintain it for six months after the occurrence of the last case. In spite of much opposition and criticism, this was resolutely carried out under Mr Walter Long, the responsible minister, and met with great success. By the spring of 1899—that is, in two years—the disease had disappeared in Great Britain, except for one area in Wales; and, with this exception, muzzling was everywhere relaxed in October 1899. It was taken off in Wales also in the following May, no case having occurred since November 1899. Rabies was then pronounced extinct. During the summer of 1900, however, it reappeared in Wales, and several counties were again placed under the order. The year 1901 was the third in succession in which no death from hydrophobia was registered in the United Kingdom. In the ten years preceding 1899, 104 deaths were registered, the death-rate reaching 30 in 1889 and averaging 29 annually. In 1902 two deaths from hydrophobia were registered. From that date to June 1909 (the latest available for the purpose of this article) no death from hydrophobia was notified in the United Kingdom.

See *Annales de l'Institut Pasteur*, from 1886; *Journal of the Board of Agriculture*, 1899; Makins, "Hydrophobia," in Treves's *System of Surgery*; Woodhead, "Rabies," in Allbutt's *System of Medicine*.

HYDROSPHERE (Gr. ὕδωρ, water, and σφαῖρα, sphere), in physical geography, a name given to the whole mass of the water of the oceans, which fills the depressions in the earth's crust, and covers nearly three-quarters of its surface. The name is used in distinction from the atmosphere, the earth's envelope of air, the lithosphere (Gr. λίθος, rock) or solid crust of the earth, and the centrosphere or interior mass within the crust. To these "spheres" some writers add, by figurative usage, the terms "biosphere," or life-sphere, to cover all living things, both animals and plants, and "psychosphere," or mind-sphere, covering all the products of human intelligence.

HYDROSTATICS (Gr. ὕδωρ, water, and the root στα-, to cause to stand), the branch of hydromechanics which discusses the equilibrium of fluids (see HYDROMECHANICS).

HYDROXYLAMINE, NH_2OH, or hydroxy-ammonia, a compound prepared in 1865 by W. C. Lossen by the reduction of ethyl nitrate with tin and hydrochloric acid. In 1870 E. Ludwig and T. H. Hein (*Chem. Centralblatt*, 1870, 1, p. 340) obtained it by passing nitric oxide through a series of bottles containing tin and hydrochloric acid, to which a small quantity of platinum tetrachloride has been added; the acid liquid is poured off when the operation is completed, and sulphuretted hydrogen is passed in; the tin sulphide is filtered off and the filtrate evaporated. The residue is extracted by absolute alcohol, which dissolves the hydroxylamine hydrochloride and a little ammonium chloride; this last substance is removed as ammonium platinochloride, and the residual hydroxylamine hydrochloride is recrystallized. E. Divers obtains it by mixing cold saturated solutions containing one molecular proportion of sodium nitrate, and two molecular proportions of acid sodium sulphite, and then adding a saturated solution of potassium chloride to the mixture. After standing for twenty-four hours, hydroxylamine potassium disulphonate crystallizes out. This is boiled for some hours with water and the solution cooled, when potassium sulphate separates first, and then hydroxylamine sulphate. E. Tafel (*Zeit. anorg. Chem.*, 1902, 31, p. 289) patented an electrolytic process, wherein 50% sulphuric acid is treated in a divided cell provided with a cathode of amalgamated lead, 50% nitric acid being gradually run into the cathode compartment. Pure anhydrous hydroxylamine has been obtained by C. A. Lobry de Bruyn from the hydrochloride, by dissolving it in absolute methyl alcohol and then adding sodium methylate. The precipitated sodium chloride is filtered, and the solution of hydroxylamine distilled in order to remove methyl alcohol, and finally fractionated under reduced pressure. The free base is a colourless, odourless, crystalline solid, melting at about 30° C., and boiling at 58° C. (under a pressure of 22 mm.). It deliquesces and oxidizes on exposure, inflames in dry chlorine and is reduced to ammonia by zinc dust. Its aqueous solution is strongly alkaline, and with acids it forms well-defined stable salts. E. Ebler and E. Schott (*J. pr. Chem.*, 1908, 78, p. 289) regard it as acting with the formula $NH_2{\cdot}OH$ towards bases, and as $NH_3{:}O$ towards acids, the salts in the latter case being of the oxonium type. It is a strong reducing agent, giving a precipitate of cuprous oxide from alkaline copper solutions at ordinary temperature, converting mercuric chloride to mercurous chloride, and precipitating metallic silver from solutions of silver salts. With aldehydes and ketones it forms oximes (*q.v.*). W. R. Dunstan (*Jour. Chem. Soc.*, 1899, 75, p. 792) found that the addition of methyl iodide to a methyl alcohol solution of hydroxylamine resulted in the formation of trimethyloxamine, $N(CH_3)_3O$.

Many substituted hydroxylamines are known, substitution taking place either in the α or β position ($\overset{\beta}{N}H_2{\cdot}\overset{\alpha}{O}H$). β-phenylhydroxylamine, $C_6H_5NH{\cdot}OH{\cdot}$, is obtained in the reduction of nitrobenzene in neutral solution (*e.g.* by the action of the aluminium-mercury couple and water), but better, according to C. Goldschmidt (*Ber.*, 1896, 29, p. 2307) by dissolving nitrobenzene in ten times its weight of ether containing a few cubic centimetres of water, and heating with excess of zinc dust and anhydrous calcium chloride for three hours on a water bath. It also appears as an intermediate product in the electrolytic reduction of nitrobenzene in sulphuric acid solution. By gentle oxidation it yields nitrosobenzene. Derivatives of the type $R_2N{\cdot}OH$ result in the action of the Grignard reagent on amyl nitrite. Dihydroxy-ammonia or nitroxyl, $NH(OH)_2$, a very unstable and highly reactive substance, has been especially studied by A. Angeli (see A. W. Stewart, *Recent Advances in Physical and Inorganic Chemistry*, 1909).

HYDROZOA, one of the most widely spread and prolific groups of aquatic animals. They are for the most part marine in habitat, but a familiar fresh-water form is the common *Hydra* of ponds and ditches, which gives origin to the name of the class. The Hydrozoa comprise the hydroids, so abundant on all shores, most of which resemble vegetable organisms to the unassisted eye; the hydrocorallines, which, as their name implies, have a massive stony skeleton and resemble corals; the jelly-fishes so called; and the Siphonophora, of which the species best known by repute is the so-called "Portuguese man-of-war" (*Physalia*), dreaded by sailors on account of its terrible stinging powers.

In external form and appearance the Hydrozoa exhibit such striking differences that there would seem at first sight to be little in common between the more divergent members of the group. Nevertheless there is no other class in the animal kingdom with better marked characteristics, or with more uniform morphological peculiarities underlying the utmost diversity of superficial characters.

All Hydrozoa, in the first place, exhibit the three structural features distinctive of the Coelentera (*q.v.*). (1) The body is built up of two layers only, an external protective and sensory layer, the ectoderm, and an internal digestive layer, the endoderm. (2) The body contains but a single internal cavity, the coelenteron or gastrovascular space, which may be greatly ramified, but is not shut off into cavities distinct from the central digestive space. (3) The generative cells are produced in either the ectoderm or endoderm, and not in a third layer arising in the embryo, distinct from the two primary layers; in other words, there is no mesoderm or coelom.

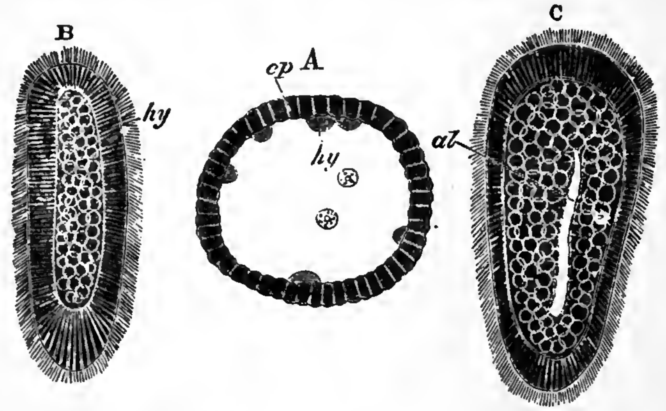
To these three characters the Hydrozoa add a fourth which is distinctive of the subdivision of the Coelenterata termed the Cnidaria; that is to say, they always possess peculiar stinging organs known as nettle-cells, or *nematocysts* (*Cnidae*), each produced in a cell forming an integral part of the animal's tissues. The Hydrozoa are thus shown to belong to the group of Coelenterata Cnidaria, and it remains to consider more fully their distinctive features, and in particular those which mark them off from the other main division of the Cnidaria, the Anthozoa (*q.v.*), comprising the corals and sea-anemones.

The great diversity, to which reference has already been made, in the form and structure of the Hydrozoa is due to two principal causes. In the first place, we find in this group two distinct types of person or individual, the polyp and the medusa (*qq.v.*), each capable of a wide range of variations; and when both polyp and medusa occur in the life-cycle of the same species, as is frequently the case, the result is an alternation of generations of a type peculiarly characteristic of the class. In the second place, the power of non-sexual reproduction by budding is practically of universal occurrence among the Hydrozoa, and by the buds failing to separate from the parent stock, colonies are produced, more or less complicated in structure and often of great size. We find that polyps may either bud other polyps or may produce medusae, and that medusae may bud medusae, though never, apparently, polyps. Hence we have a primary subdivision of the colonies of Hydrozoa into those produced by budding of polyps and those produced by budding of medusae. The former may contain polyp-persons and medusa-persons, either one kind alone or both kinds combined; the latter will contain only medusa-persons variously modified.

The morphology of the Hydrozoa reduces itself, therefore, to a consideration of the morphology of the polyp, of the medusa and of the colony. Putting aside the last-named, for a detailed account of which see HYDROMEDUSAE, we can best deal with the peculiarities of the polyp and medusa from a developmental point of view.

In the development of the Hydrozoa, and indeed of the Cnidaria generally, the egg usually gives rise to an oval larva which swims about by means of a coating of cilia on the surface of the body. This very characteristic larva is termed a *planula*, but though very uniform externally, the planulae of different species, or of the same species at different periods, do not always represent the same stage of embryonic development internally. On examining more minutely the course of the development, it is found that the ovum goes through the usual process of cleavage, always total and regular in this group, and so gives rise to a hollow sphere or ovoid with the wall composed of a single layer of cells, and containing a spacious cavity, the blastocoele or segmentation-cavity. This is the *blastula* stage occurring universally in all Metazoa, probably representing an ancestral Protozoan colony in phylogeny. Next the blastula gives rise to an internal mass of cells (fig. 1, *hy*) which come from the wall either by immigration (fig. 1, A) or by splitting off (delamination). The formation of an inner cell-mass converts the single-layered blastula (monoblastula) into a double-layered embryo (diblastula) which may be termed a parenchymula, since at first the inner cell-mass forms an irregular parenchyma which may entirely fill up and obliterate the segmentation cavity (fig. 1, B). At a later stage, however, the cells of the inner mass arrange themselves in a definite layer surrounding an internal cavity (fig. 1, C, *al*), which soon acquires an opening to the exterior at one pole, and so forms the characteristic embryonic stage of all Enterozoa known as the *gastrula* (fig. 2). In this stage the body is composed of two layers, ectoderm (*d*) externally, and endoderm (*c*) internally, surrounding a central cavity, the *archenteron* (*b*), which communicates with the exterior by a pore (*a*), the *blastopore*.

Thus a planula larva may be a blastula, or but slightly advanced beyond this stage, or it may be (and most usually is) a parenchymula; or in some cases (Scyphomedusae) it may be a gastrula. It should be added that the process of development, the gastrulation as it is termed, may be shortened by the immigration of cells taking place

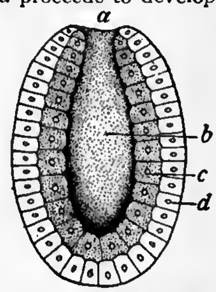


From Balfour, after Kowalewsky.

FIG. 1.—Formation of the Diblastula of *Eucope* (one of the Calyptoblastic *Hydromedusae*) by immigration. A, B, C, three successive stages. *ep*, Ectoderm; *hy*, endoderm; *al*, enteric cavity.

at one pole only, and in a connected layer with orderly arrangement, so that the gastrula stage is reached at once from the blastula without any intervening parenchymula stage. This is a process of gastrulation by invagination which is found in all animals above the Coelenterata, but which is very rare in the Cnidaria, and is known only in the Scyphomedusae amongst the Hydrozoa.

After the gastrula stage, which is found as a developmental stage in all Enterozoa, the embryo of the Hydrozoa proceeds to develop characters which are peculiar to the Coelenterata only. Round the blastopore hollow outgrowths, variable in number, arise by the evagination of the entire body-wall, both ectoderm and endoderm. Each outgrowth contains a prolongation of the archenteric cavity (compare figs. 2 and 3, A). In this way is formed a ring of tentacles, the most characteristic organs of the Cnidaria. They surround a region which is termed the peristome, and which contains in the centre the blastopore, which becomes the adult mouth. The archenteron becomes the gastrovascular system or coelenteron. Between the ectoderm and endoderm a gelatinous supporting layer, termed the mesogloea, makes its appearance. The gastrula has now become an *actinula*, which may be termed the distinctive larva of the Cnidaria, and doubtless represents in a transitory manner the common ancestor of the group. In no case known, however, does the actinula become the adult, sexually mature individual, but always undergoes further modifications, whereby it develops into either a polyp or a medusa.



From Gegenbaur's *Elements of Comparative Anatomy.*

FIG. 2.—Diagram of a Diblastula.
a, Blastopore.
b, Archenteric cavity.
c, Endoderm.
d, Ectoderm.

To become a polyp, the actinula (fig. 3, A) becomes attached to some firm object by the pole farthest from the mouth, and its growth preponderates in the direction of the principal axis, that is to say, the axis passing through the mouth (fig. 3, *a-b*). As a result the body becomes columnar in form (fig. 3, B), and without further change passes into the characteristic polyp-form (see POLYP).

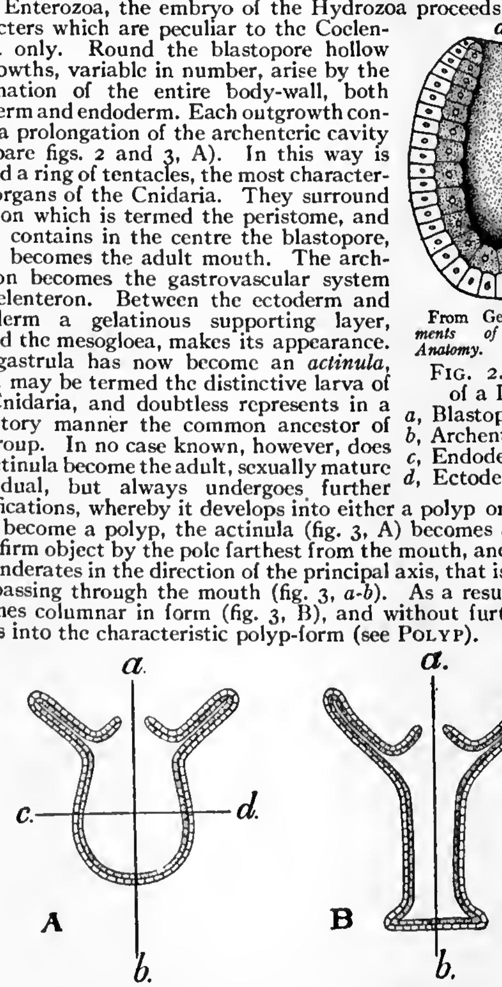


FIG. 3.—Diagram showing the change of the Actinula (A) into a Polyp (B); *a-b*, principal (vertical) axis; *c-d*, horizontal axis. The endoderm is shaded, the ectoderm is left clear.

It is convenient to distinguish two types of polyp by the names hydro polyp and anthopolyp, characteristic of the Hydrozoa and

Anthozoa respectively. In the hydropolyp the body is typically elongated, the height of the column being far greater than the diameter. The peristome is relatively small and the mouth is generally raised on a projecting spout or *hypostome*. The ectoderm loses entirely the ciliation which it had in the planula and actinula stages and commonly secretes on its external surface a protective or supporting investment, the perisarc. Contrasting with this, the anthopolyp is generally of squat form, the diameter often exceeding the height; the peristome is wide, a hypostome is lacking, and the ectoderm, or so much of it as is exposed, *i.e.* not covered by secretion of skeletal or other investment, retains its ciliation throughout life. The internal structural differences are even more characteristic. In the hydropolyp the blastopore of the embryo forms the adult mouth situated at the extremity of the hypostome, and the ectoderm and

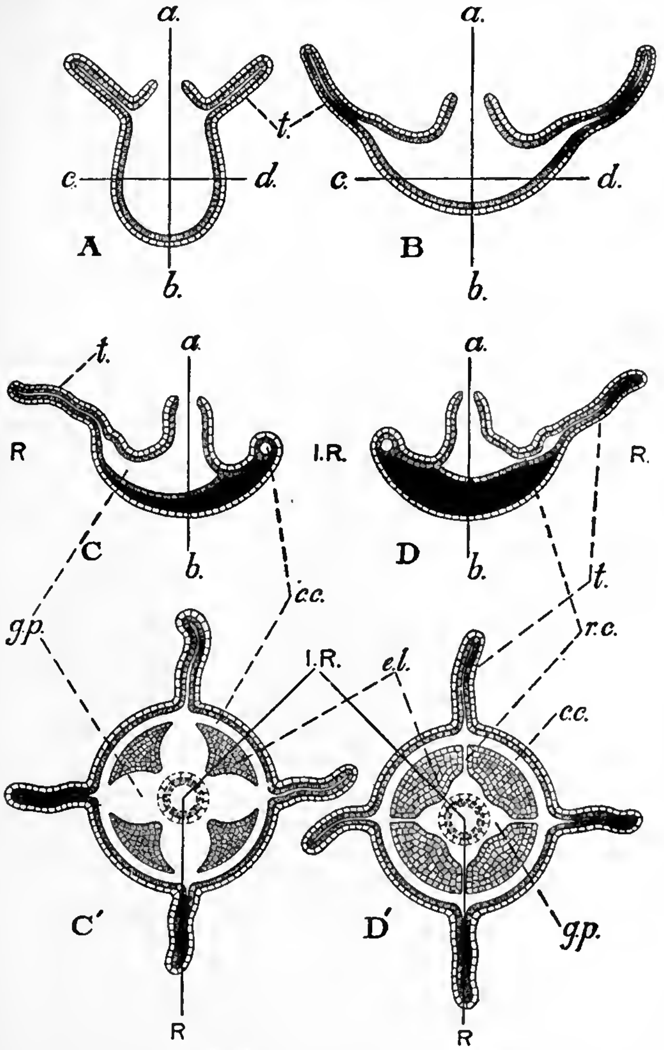

FIG. 4.—Diagram showing the change of the Actinula into a Medusa. A, Vertical section of the actinula; *a-b* and *c-d* as in fig. 3, B, transitional stage, showing preponderating growth in the horizontal plane. C,C′, D,D′, two types of medusa organization; C and D are composite sections, showing a radius (R) on one side, an interradius (IR) on the other; C′ and D′ are plans; the mouth and manubrium are indicated at the centre, leading into the gastral cavity subdivided by the four areas of concrescence in each interradius (IR). *t*, tentacle; *g.p*, gastric pouch; *r.c*, radial canal not present in C and C′; *c.c*, circular or ring-canal; *e.l*, endoderm-lamella formed by concrescence. For a more detailed diagram of medusa-structure see article MEDUSA.

endoderm meet at this point. In the anthopolyp the blastopore is carried inwards by an in-pushing of the body-wall of the region of the peristome, so that the adult mouth is an opening leading into a short ectodermal oesophagus or stomodaeum, at the bottom of which is the blastopore. Further, in the hydropolyp the digestive cavity either remains simple and undivided and circular in transverse section, or may show ridges projecting internally, which in this case are formed of endoderm alone, without any participation of the mesogloea. In the anthopolyp, on the other hand, the digestive cavity is always subdivided by so-called mesenteries, in-growths of the endoderm containing vertical lamellae of mesogloea (see ANTHOZOA). In short, the hydropolyp is characterized by a more simple type of organization than the anthopolyp, and is in most respects less modified from the actinula type of structure.

Returning now to the actinula, this form may, as already stated, develop into a medusa, a type of individual found only in the Hydrozoa, as here understood. To become a medusa, the actinula grows scarcely at all in the direction of the principal axis, but greatly along a plane at right angles to it. Thus the body becomes umbrella-shaped, the concave side representing the peristome, and the convex side the column, of the polyp. Hence the tentacles are found at the edge of the umbrella, and the hypostome forms usually a projecting tube, with the mouth at the extremity, forming the *manubrium* or handle of the umbrella. The medusa has a pronounced radial symmetry, and the positions of the primary tentacles, usually four in number, mark out the so-called *radii*, alternating with which are four *interradii*. The ectoderm retains its ciliation only in the sensory organs. The mesogloea becomes enormously increased in quantity (hence the popular name "jelly-fish"), and in correlation with this the endoderm-layer lining the coelenteron becomes pressed together in the interradial areas and undergoes concrescence, forming a more or less complicated gastrovascular system (see MEDUSA). It is sufficient to state here that the medusa is usually a free-swimming animal, floating mouth downwards on the open seas, but in some cases it may be attached by its aboral pole, like a polyp, to some firm basis, either temporarily or permanently.

Thus the development of the two types of individual seen in the Hydrozoa may be summarized as follows:—

	Egg
Free	Blastula
"Planula"	Parenchymula
Stage	Gastrula
	Actinula
	↙ ↘
	Polyp Medusa

This development, though probably representing the primitive sequence of events, is never actually found in its full extent, but is always abbreviated by omission or elimination of one or more of the stages. We have already seen that the parenchymula stage is passed over when the gastrulation is of the invaginate type. On the other hand, the parenchymula may develop directly into the actinula or even into the polyp, with suppression of the intervening steps. Great apparent differences may also be brought about by variations in the period at which the embryo is set free as a larva, and since two free-swimming stages, planula and actinula, are unnecessary, one or other of them is always suppressed. A good example of this is seen in two common genera of British hydroids, *Cordylophora* and *Tubularia*. In *Cordylophora* the embryo is set free at the parenchymula stage as a planula which fixes itself and develops into a polyp, both gastrula and actinula stages being suppressed. In *Tubularia*, on the other hand, the parenchymula develops into an actinula within the maternal tissues, and is then set free, creeps about for a time, and after fixing itself, changes into a polyp; hence in this case the planula-stage, as a free larva, is entirely suppressed.

The Hydrozoa may be defined, therefore, as Cnidaria in which two types of individual, the polyp and the medusa, may be present, each type developed along divergent lines from the primitive actinula form. The polyp (hydropolyp) is of simple structure, and never has an ectodermal oesophagus or mesenteries.[1] The general ectoderm loses its cilia, which persist only in the sensory cells, and it frequently secretes external protective or supporting structures. An internal mesogloeal skeleton is not found.

The class is divisible into two main divisions or sub-classes, Hydromedusae and Scyphomedusae, of which definitions and detailed systematic accounts will be found under these headings.

Hérouard, *Traité de zoologie concrète*, ii. part 2, *Les Coelentérés* (1901); G. H. Fowler, "The Hydromedusae and Scyphomedusae" in E. R. Lankester's *Treatise on Zoology*, ii. chapters iv. and v. (1900); S. J. Hickson, "Coelenterata and Ctenophora," *Cambridge Natural History*, i. chapters x.-xv. (1906). (E. A. M.)

HYENA, a name applicable to all the representatives of the mammalian family *Hyaenidae*, a group of Carnivora (*q.v.*) allied to the civets. From all other large Carnivora except the African hunting-dog, hyenas are distinguished by having only four toes on each foot, and are further characterized by the length of the fore-legs as compared with the hind pair, the non-retractile claws, and the enormous strength of the jaws and teeth, which enables them to break the hardest bones and to retain what they have seized with unrelaxing grip.

[1] See further under SCYPHOMEDUSAE.

The striped hyena (*Hyaena striata*) is the most widely distributed species, being found throughout India, Persia, Asia Minor, and North and East Africa, the East African form constituting a distinct race, *H. striata schillingsi*; while there are also several distinct Asiatic races. The species resembles a wolf in size, and is greyish-brown in colour, marked with indistinct longitudinal stripes of a darker hue, while the legs are transversely striped. The hairs on the body are long, especially on the ridge of the neck and back, where they form a distinct mane, which is continued along the tail. Nocturnal in habits,

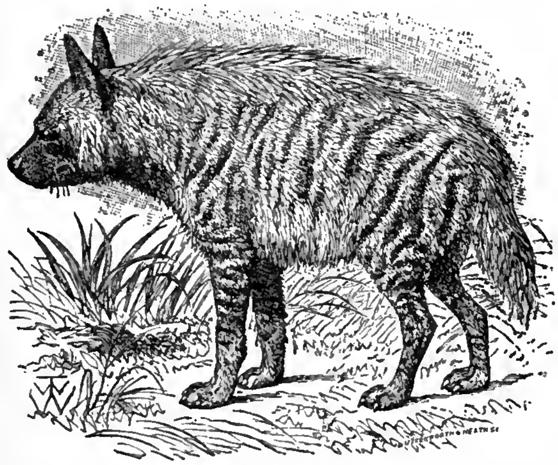

FIG. 1.—The Striped Hyena (*Hyaena striata*).

it prefers by day the gloom of caves and ruins, or of the burrows which it occasionally forms, and issues forth at sunset, when it commences its unearthly howling. When the animal is excited, the howl changes into what has been compared to demoniac laughter, whence the name of "laughing-hyena." These creatures feed chiefly on carrion, and thus perform useful service by devouring remains which might otherwise pollute the air. Even human dead are not safe from their attacks, their powerful claws enabling them to gain access to newly interred bodies in cemeteries. Occasionally (writes Dr W. T. Blanford) sheep or

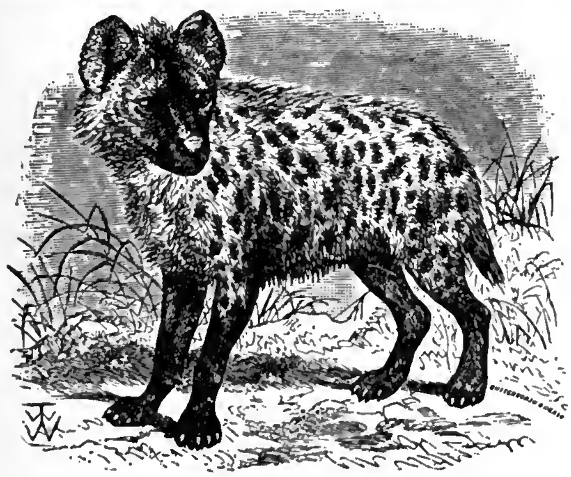

FIG. 2.—The Spotted Hyena (*Hyaena crocuta*).

goats, and more often dogs, are carried off, and the latter, at all events, are often taken alive to the animal's den. This species appears to be solitary in habits, and it is rare to meet with more than two together. The cowardice of this hyena is proverbial; despite its powerful teeth, it rarely attempts to defend itself. A very different animal is the spotted hyena, *Hyaena* (*Crocuta*) *crocuta*, which has the sectorial teeth of a more cat-like type, and is marked by dark-brown spots on a yellowish ground, while the mane is much less distinct. At the Cape it was formerly common, and occasionally committed great havoc among the cattle, while it did not hesitate to enter the Kaffir dwellings at night and carry off children sleeping by their mothers. By persistent trapping and shooting, its numbers have now been considerably reduced, with the result, however, of making it exceedingly wary, so that it is not readily caught in any trap with which it has had an opportunity of becoming acquainted. Its range extends from Abyssinia to the Cape. The Abyssinian form has been regarded as a distinct species, under the name of *H. liontiewi*, but this, like various more southern forms, is but regarded as a local race. The brown hyena (*H. brunnea*) is South African, ranging to Angola on the west and Kilimanjaro on the east. In size it resembles the striped hyena, but differs in appearance, owing to the fringe of long hair covering the neck and fore part of the back. The general hue is ashy-brown, with the hair lighter on the neck (forming a collar), chest and belly; while the legs are banded with dark brown. This species is not often seen, as it remains concealed during the day. Those frequenting the coast feed on dead fish, crabs and an occasional stranded whale, though they are also a danger to the sheep and cattle kraal. Strand-wolf is the local name at the Cape.

Although hyenas are now confined to the warmer regions of the Old World, fossil remains show that they had a more northerly range during Tertiary times; the European cave-hyena being a form of the spotted species, known as *H. crocuta spelaea*. Fossil hyenas occur in the Lower Pliocene of Greece, China, India, &c.; while remains indistinguishable from those of the striped species have been found in the Upper Pliocene of England and Italy.

HYÈRES, a town in the department of the Var in S.E. France, 11 m. by rail E. of Toulon. In 1906 the population of the commune was 17,790, of the town 10,464; the population of the former was more than doubled in the last decade of the 19th century. Hyères is celebrated (as is also its fashionable suburb, Costebelle, nearer the seashore) as a winter health resort. The town proper is situated about 2½ m. from the seashore, and on the south-western slope of a steep hill (669 ft., belonging to the Maurettes chain, 961 ft.), which is one of the westernmost spurs of the thickly wooded Montagnes des Maures. It is sheltered from the north-east and east winds, but is exposed to the cold north-west wind or *mistral*. Towards the south and south-east a fertile plain, once famous for its orange groves, but now mainly covered by vineyards and farms, stretches to the sea, while to the south-west, across a narrow valley, rises a cluster of low hills, on which is the suburb of Costebelle. The older portion of the town is still surrounded, on the north and east, by its ancient, though dilapidated medieval walls, and is a labyrinth of steep and dirty streets. The more modern quarter which has grown up at the southern foot of the hill has handsome broad boulevards and villas, many of them with beautiful gardens, filled with semi-tropical plants. Among the objects of interest in the old town are: the house (Rue Rabaton, 7) where J. B. Massillon (1663–1742), the famous pulpit orator, was born; the parish church of St Louis, built originally in the 13th century by the Cordelier or Franciscan friars, but completely restored in the earlier part of the 19th century; and the site of the old château, on the summit of the hill, now occupied by a villa. The plain between the new town and the sea is occupied by large nurseries, an excellent *jardin d'acclimatation*, and many market gardens, which supply Paris and London with early fruits and vegetables, especially artichokes, as well as with roses in winter. There are extensive salt beds (*salines*) both on the peninsula of Giens, S. of the town, and also E. of the town. To the east of the Giens peninsula is the fine natural harbour of Hyères, as well as three thinly populated islands (the Stoechades of the ancients), Porquerolles, Port Cros and Le Levant, which are grouped together under the common name of Îles d'Hyères.

The town of Hyères seems to have been founded in the 10th century, as a place of defence against pirates, and takes its name from the *aires* (*hierbo* in the Provençal dialect), or threshing-floors for corn, which then occupied its site. It passed from the possession of the viscounts of Marseilles to Charles of Anjou, count of Provence, and brother of St Louis (the latter landed here in 1254, on his return from Egypt). The château was dismantled by Henri IV., but thanks to its walls, the town resisted in 1707 an attack made by the duke of Savoy.

See Ch. Lenthéric, *La Provence Maritime ancienne et moderne* (chap. 5) (Paris, 1880). (W. A. B. C.)

HYGIEIA, in Greek mythology, the goddess of health. It seems probable that she was originally an abstraction, subsequently personified, rather than an independent divinity of very ancient date. The question of the original home of her worship has been much discussed. The oldest traces of it, so far as is known at present, are to be found at Titane in the territory of Sicyon, where she was worshipped together with Asclepius, to whom she appears completely assimilated, not an independent personality. Her cult was not introduced at Epidaurus till a late date, and therefore, when in 420 B.C. the worship of Asclepius was introduced at Athens coupled with that of Hygieia, it is not to be inferred that she accompanied him from Epidaurus, or that she is a Peloponnesian importation at all. It is most probable that she was invented at the time of the introduction of Asclepius, after the sufferings caused by the plague had directed special attention to sanitary matters. The already existing worship of Athena Hygieia had nothing to do with Hygieia the goddess of health, but merely denoted the recognition of the power of healing as one of the attributes of Athena, which gradually became crystallized into a concrete personality. At first no special relationship existed between Asclepius and Hygieia, but gradually she came to be regarded as his daughter, the place of his wife being already secured by Epione. Later Orphic hymns, however, and Herodas iv. 1-9, make her the wife of Asclepius. The cult of Hygieia then spread concurrently with that of Asclepius, and was introduced at Rome from Epidaurus in 293, by which time she may have been admitted (which was not the case before) into the Epidaurian family of the god. Her proper name as a Romanized Greek importation was Valetudo, but she was gradually identified with Salus, an older genuine Italian divinity, to whom a temple had already been erected in 302. While in classical times Asclepius and Hygieia are simply the god and goddess of health, in the declining years of paganism they are protecting divinities generally, who preserve mankind not only from sickness but from all dangers on land and sea. In works of art Hygieia is represented, together with Asclepius, as a maiden of benevolent appearance, wearing the chiton and giving food or drink to a serpent out of a dish.

See the article by H. Lechat in Daremberg and Saglio's *Dictionnaire des antiquités*, with full references to authorities; and E. Thrämer in Roscher's *Lexikon der Mythologie*, with a special section on the modern theories of Hygieia.

HYGIENE (Fr. *hygiène*, from Gr. ὑγιαίνειν, to be healthy), the science of preserving health, its practical aim being to render "growth more perfect, decay less rapid, life more vigorous, death more remote." The subject is thus a very wide one, embracing all the agencies which affect the physical and mental well-being of man, and it requires acquaintance with such diverse sciences as physics, chemistry, geology, engineering, architecture, meteorology, epidemiology, bacteriology and statistics. On the personal or individual side it involves consideration of the character and quality of food and of water and other beverages; of clothing; of work, exercise and sleep; of personal cleanliness, of special habits, such as the use of tobacco, narcotics, &c.; and of control of sexual and other passions. In its more general and public aspects it must take cognizance of meteorological conditions, roughly included under the term climate; of the site or soil on which dwellings are placed; of the character, materials and arrangement of dwellings, whether regarded individually or in relation to other houses among which they stand; of their heating and ventilation; of the removal of excreta and other effete matters; of medical knowledge relating to the incidence and prevention of disease; and of the disposal of the dead.

These topics will be found treated in such articles as DIETETICS, FOOD, FOOD-PRESERVATION, ADULTERATION, WATER, HEATING, VENTILATION, SEWERAGE, BACTERIOLOGY, HOUSING, CREMATION, &c. For legal enactments which concern the sanitary well-being of the community, see PUBLIC HEALTH.

HYGINUS, eighth pope. It was during his pontificate (*c.* 137–140) that the gnostic heresies began to manifest themselves at Rome.

HYGINUS (surnamed GROMATICUS, from *gruma*, a surveyor's measuring-rod), Latin writer on land-surveying, flourished in the reign of Trajan (A.D. 98–117). Fragments of a work on legal boundaries attributed to him will be found in C. F. Lachmann, *Gromatici Veteres*, i. (1848).

A treatise on Castrametation (*De Munitionibus Castrorum*), also attributed to him, is probably of later date, about the 3rd century A.D. (ed. W. Gemoll, 1879; A. von Domaszewski, 1887).

HYGINUS, GAIUS JULIUS, Latin author, a native of Spain (or Alexandria), was a pupil of the famous Cornelius Alexander Polyhistor and a freedman of Augustus, by whom he was made superintendent of the Palatine library (Suetonius, *De Grammaticis*, 20). He is said to have fallen into great poverty in his old age, and to have been supported by the historian Clodius Licinus. He was a voluminous author, and his works included topographical and biographical treatises, commentaries on Helvius Cinna and the poems of Virgil, and disquisitions on agriculture and bee-keeping. All these are lost.

Under the name of Hyginus two school treatises on mythology are extant: (1) *Fabularum Liber*, some 300 mythological legends and celestial genealogies, valuable for the use made by the author of the works of Greek tragedians now lost; (2) *De Astronomia*, usually called *Poetica Astronomica*, containing an elementary treatise on astronomy and the myths connected with the stars, chiefly based on the Καταστερισμοί of Eratosthenes. Both are abridgments and both are by the same hand; but the style and Latinity and the elementary mistakes (especially in the rendering of the Greek originals) are held to prove that they cannot have been the work of so distinguished a scholar as C. Julius Hyginus. It is suggested that these treatises are an abridgment (made in the latter half of the 2nd century) of the *Genealogiae* of Hyginus by an unknown grammarian, who added a complete treatise on mythology.

EDITIONS.—*Fabulae*, by M. Schmidt (1872); *De Astronomia*, by B. Bunte (1875); see also Bunte, *De C. Julii Hygini, Augusti Liberti, Vita et Scriptis* (1846).

HYGROMETER (Gr. ὑγρός, moist, μέτρον, a measure), an instrument for measuring the absolute or relative amount of moisture in the atmosphere; an instrument which only qualitatively determines changes in the humidity is termed a "hygroscope." The earlier instruments generally depended for their action on the contraction or extension of substances when exposed to varying degrees of moisture; catgut, hair, twisted cords and wooden laths, all of which contract with an increase in the humidity and vice versa, being the most favoured materials. The familiar "weather house" exemplifies this property. This toy consists of a house provided with two doors, through which either a man or woman appears according as the weather is about to be wet or fine. This action is effected by fixing a catgut thread to the base on which the figures are mounted, in such a manner that contraction of the thread rotates the figures so that the man appears and extension so that the woman appears.

Many of the early forms are described in C. Hutton, *Math. and Phil. Dictionary* (1815). The modern instruments, which utilize other principles, are described in METEOROLOGY: II. *Methods and Apparatus*.

HYKSOS, or "SHEPHERD KINGS," the name of the earliest invaders of Egypt of whom we have definite evidence in tradition. Josephus (*c. Apion.* i. 14), who identifies the Hyksos with the Israelites, preserves a passage from the second book of Manetho giving an account of them. (It may be that Josephus had it, not direct from Manetho's writings, but through the garbled version of some Alexandrine compiler.) In outline it is as follows. In the days of a king of Egypt named Timaeus the land was suddenly invaded from the east by men of ignoble race, who conquered it without a struggle, destroyed cities and temples, and slew or enslaved the inhabitants. At length they elected a king named Salatis, who, residing at Memphis, made all Egypt tributary, and established garrisons in different parts, especially eastwards, fearing the Assyrians. He built also a great fortress at Avaris, in the Sethroite nome, east of the Bubastite branch of the Nile. Salatis was followed in succession by Beon, Apachnas, Apophis, Jannas and Asses. These six kings reigned 198 years and 10 months, and all aimed at extirpating the Egyptians. Their whole race was named Hyksos, *i.e.* "shepherd kings," and some say they were Arabs (another explanation found by Josephus is "captive shepherds"). When they and their successors had held Egypt for 511 years, the kings of the Thebais and other parts of Egypt rebelled, and a long and mighty war began. Misphragmuthosis worsted the "Shepherds" and shut them up in Avaris; and his son Thutmosis, failing to capture the stronghold, allowed them to depart; whereupon they went forth, 240,000 in number, established themselves in Judea and built Jerusalem.

In Manetho's list of kings, the six above named (with many variations in detail) form the XVth dynasty, and are called "six foreign Phoenician kings." The XVIth dynasty is of thirty-two "Hellenic (*sic?*) shepherd kings," the seventeenth is of "shepherds and Theban kings" (reigning simultaneously). The lists vary greatly in different versions, but the above seems the most reasonable selection of readings to be made. For "Hellenic" see below. The supposed connexion with the Israelites has made the problem of the Hyksos attractive, but light is coming upon it very slowly. In 1847 E. de Rougé proved from a fragment of a story in the papyri of the British Museum, that Apopi was one of the latest of the Hyksos kings, corresponding to Aphobis; he was king of the "pest" and suppressed the worship of the Egyptian gods, and endeavoured to make the Egyptians worship his god Setekh or Seti; at the same time an Egyptian named Seqenenrē reigned in Thebes, more or less subject to Aphobis. The city of Hawari (Avaris) was also mentioned in the fragment.

In 1850 a record of the capture of this city from the Hyksos by Ahmosi, the founder of the eighteenth dynasty, was discovered by the same scholar. A large class of monuments was afterwards attributed to the Hyksos, probably in error. Some statues and sphinxes, found in 1861 by Mariette at Tanis (in the north-east of the Delta), which had been usurped by later kings, had peculiar "un-Egyptian" features. One of these bore the name of Apopi engraved lightly on the shoulder; this was evidently a usurper's mark, but from the whole circumstances it was concluded that these, and others of the same type of features found elsewhere, must have belonged to the Hyksos. This view held the field until 1893, when Golénischeff produced an inferior example bearing its original name, which showed that in this case it represented Amenemhe III. In consequence it is now generally believed that they all belong to the twelfth dynasty. Meanwhile a headless statue of a king named Khyan, found at Bubastis, was attributed on various grounds to the Hyksos, the soundest arguments being his foreign name and the boastful un-Egyptian epithet "beloved of his *ka*," where "beloved of Ptah" or some other god was to be expected. His name was immediately afterwards recognized on a lion found as far away from Egypt as Bagdad. Flinders Petrie then pointed out a group of kings named on scarabs of peculiar type, which, including Khyan, he attributed to the period between the Old Kingdom and the New, while others were in favour of assigning them all to the Hyksos, whose appellation seemed to be recognizable in the title Hek-khos, "ruler of the barbarians," borne by Khyan. The extraordinary importance of Khyan was further shown by the discovery of his name on a jar-lid at Cnossus in Crete. Semitic features were pointed out in the supposed Hyksos names, and Petrie was convinced of their date by his excavations of 1905–1906 in the eastern Delta. Avaris is generally assigned to the region towards Pelusium on the strength of its being located in the Sethroite nome by Josephus, but Petrie thinks it was at Tell el-Yahudiyeh (Yehudia), where Hyksos scarabs are common. From the remains of fortifications there he argues that the Hyksos were uncivilized desert people, skilled in the use of the bow, and must thus have destroyed by their archery the Egyptian armies trained to fight hand-to-hand; further, that their hordes were centered in Syria, but were driven thence by a superior force in the East to take refuge in the islands and became a sea-power—whence the strange description "Hellenic" in Manetho, which most editors have corrected to ἄλλοι, "others." Besides the statue of Khyan, blocks of granite with the name of Apopi have been found in Upper Egypt at Gebelen and in Lower Egypt at Bubastis. The celebrated Rhind mathematical papyrus was copied in the reign of an Apopi from an original of the time of Amenemhe III. Large numbers of Hyksos scarabs are found in Upper and Lower Egypt, and they are not unknown in Palestine. Khyan's monuments, inconspicuous as they are, actually extend over a wider area—from Bagdad to Cnossus—than those of any other Egyptian king.

It is certain that this mysterious people were Asiatic, for they are called so by the Egyptians. Though Seth was an Egyptian god, as god of the Hyksos he represents some Asiatic deity. The possibility of a connexion between the Hyksos and the Israelites is still admitted in some quarters. Hatred of these impious foreigners, of which there is some trace in more than one text, aroused amongst the Egyptians (as nothing ever did before or since) that martial spirit which carried the armies of Tethmosis to the Euphrates.

Besides the histories of Egypt, see J. H. Breasted, *Ancient Records of Egypt*; Historical Documents ii. 4, 125; G. Maspero, *Contes populaires*, 3me éd. p. 236; W. M. F. Petrie, *Hyksos and Israelite Cities*, p. 67; Golénischeff in *Recueil de travaux*, xv. p. 131. (F. Ll. G.)

HYLAS, in Greek legend, son of Theiodamas, king of the Dryopians in Thessaly, the favourite of Heracles and his companion on the Argonautic expedition. Having gone ashore at Kios in Mysia to fetch water, he was carried off by the nymphs of the spring in which he dipped his pitcher. Heracles sought him in vain, and the answer of Hylas to his thrice-repeated cry was lost in the depths of the water. Ever afterwards, in memory of the threat of Heracles to ravage the land if Hylas were not found, the inhabitants of Kios every year on a stated day roamed the mountains, shouting aloud for Hylas (Apollonius Rhodius i. 1207; Theocritus xiii.; Strabo xii. 564; Propertius i. 20; Virgil, *Ecl.* vi. 43). But, although the legend is first told in Alexandrian times, the "cry of Hylas" occurs long before as the "Mysian cry" in Aeschylus (*Persae*, 1054), and in Aristophanes (*Plutus*, 1127) "to cry Hylas" is used proverbially of seeking something in vain. Hylas, like Adonis and Hyacinthus, represents the fresh vegetation of spring, or the water of a fountain, which dries up under the heat of summer. It is suggested that Hylas was a harvest deity and that the ceremony gone through by the Kians was a harvest festival, at which the figure of a boy was thrown into the water, signifying the dying vegetation-spirit of the year.

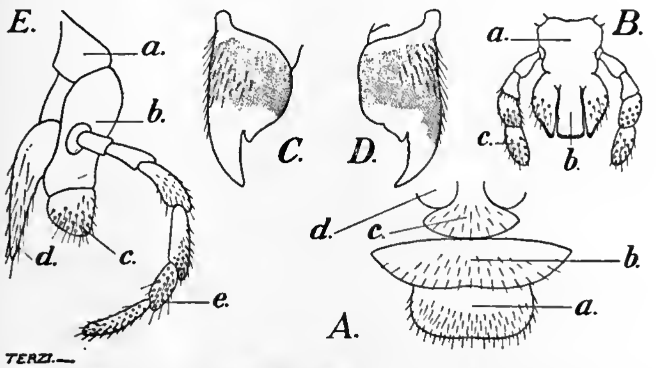
See G. Türk in *Breslauer Philologische Abhandlungen*, vii. (1895); W. Mannhardt, *Mythologische Forschungen* (1884).

HYLOZOISM (Gr. ὕλη, matter, ζωή, life), in philosophy, a term applied to any system which explains all life, whether physical or mental, as ultimately derived from matter ("cosmic matter," *Weldstoff*). Such a view of existence has been common throughout the history of thought, and especially among physical scientists. Thus the Ionian school of philosophy, which began with Thales, sought for the beginning of all things in various material substances, water, air, fire (see Ionian School). These substances were regarded as being in some sense alive, and taking some active part in the development of being. This primitive hylozoism reappeared in modified forms in medieval and Renaissance thought, and in modern times the doctrine of materialistic monism is its representative. Between modern materialism and hylozoism proper there is, however, the distinction that the ancients, however vaguely, conceived the elemental matter as being in some sense animate if not actually conscious and conative.

HYMEN, or Hymenaeus, originally the name of the song sung at marriages among the Greeks. As usual the name gradually produced the idea of an actual person whose adventures gave rise to the custom of this song. He occurs often in association with Linus and Ialemus, who represent similar personifications, and is generally called a son of Apollo and a Muse. As the son of Dionysus and Aphrodite, he was regarded as a god of fruitfulness. In Attic legend he was a beautiful youth who, being in love with a girl, followed her in a procession to Eleusis disguised as a woman, and saved the whole band from pirates. As reward he obtained the girl in marriage, and his happy married life caused him ever afterwards to be invoked in marriage songs (Servius on Virgil, *Aen.* i. 651). According to another story, he was a youth who was killed by the fall of his house on his wedding day; hence he was invoked to propitiate him and avert a similar fate from others (Servius, *loc. cit.*). He is represented in works of art as an effeminate-looking, winged youth, carrying a bridal torch and wearing a nuptial veil. The marriage song was sung, with musical accompaniment, during the procession of the bride from her parents' house to that of the bridegroom, Hymenaeus being invoked at the end of each portion.

See R. Schmidt, *De Hymenaeo et Talasio* (1886), and J. A. Hild in Daremberg and Saglis's *Dictionnaire des antiquités*.

HYMENOPTERA (Gr. ὑμήν, a membrane, and πτερόν, a wing), a term used in zoological classification for one of the most important orders of the class *Hexapoda* (*q.v.*). The order was founded by Linnaeus (*Systema Naturae*, 1735), and is still recognized by



After C. L. Marlatt, *Bur. Ent. Bull. 3, N.S., U.S. Dept. Agric.*

FIG. 1.—A, Front of head of Sawfly (*Pachynematus*); *a*, labrum; *b*, clypeus; *c*, vertex; *d*, *d*, antennal cavities. C and D, Mandibles. all naturalists in the sense proposed by him, to include the sawflies, gall-flies, ichneumon-flies and their allies, ants, wasps and bees. The relationship of the Hymenoptera to other orders of insects is discussed in the article HEXAPODA, but it may be mentioned here that in structure the highest members of the order are remarkably specialized, and that in the perfection of their instincts they stand at the head of all insects and indeed of all invertebrate animals. About 30,000 species of Hymenoptera are now known.

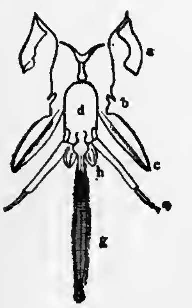

FIG. 2.—Jaws of Hive-bee (*Apis mellifica*). Magnified about 6½ times. *a*, mandible; *b*, *c*, palp and lacinia of first maxilla; *d*, *e*, *g*, *h*, mentum, palp, fused laciniae (ligula or "tongue") and galea of 2nd maxillae.

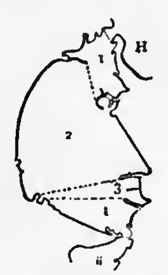

After C. Janet, *Mem. Soc. Zool. France* (1898).

Fig. 3.—Median section through mid-body of female Red Ant (*Myrmica rubra*). H, Head; 1, 2, 3, the thoracic segments; i., ii., the first and second abdominal segments; i., being the propodeum.

Characters.—In all Hymenoptera the mandibles (fig. 1, C, D) are well developed, being adapted, as in the more lowly winged insects, such as the Orthoptera, for biting. The more generalized Hymenoptera have the second maxillae but slightly modified, their inner lobes being fused to form a *ligula* (fig. 1, B, *b*). In the higher families this structure becomes elongated (fig. 2, *g*) so as to form an elaborate sucking-organ or "tongue." These insects are able, therefore, to bite as well as to suck, whereas most insects which have acquired the power of suction have lost that of biting. Both fore- and hind-wings are usually present, both pairs being membranous, the hind-wings small and not folded when at rest, each provided along the costa with a row of curved hooks which catch on to a fold along the dorsum of the adjacent fore-wing during flight. A large number of Hymenoptera are, however, entirely wingless—at least as regards one sex or form of the species. One of the most remarkable features is the close union of the foremost abdominal segment (fig. 3, i.) with the metathorax, of which it often seems to form a part, the apparent first abdominal segment being, in such case, really the second (fig. 3, ii.). The true first segment, which undergoes a more or less complete fusion with the thorax is known as the "median segment" or *propodeum*. In female Hymenoptera the typical insectan ovipositor with its three pairs of processes is well developed, and in the higher families this organ becomes functional as a sting (fig. 5)—used for offence and defence. As regards their life history, all Hymenoptera undergo a "complete" metamorphosis. The larva is soft-skinned (eruciform), being either a caterpillar (fig. 6, *b*) or a legless grub (fig. 7, *a*), and the pupa is free (fig. 7, *c*), *i.e.* with the appendages not fixed to the body, as is the case in the pupa of most moths.

Structure.—The head of a hymenopterous insect bears three simple eyes (ocelli) on the front and vertex in addition to the large compound

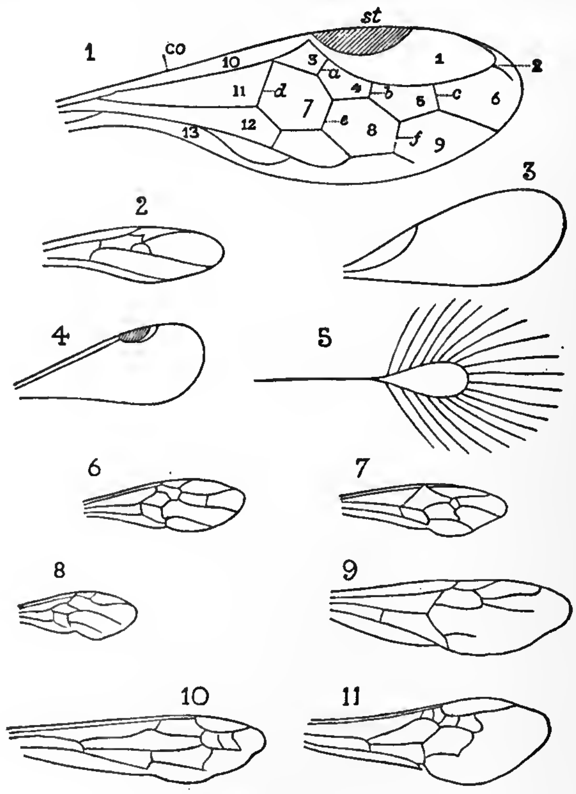

FIG. 4.—Fore-Wings of Hymenoptera.

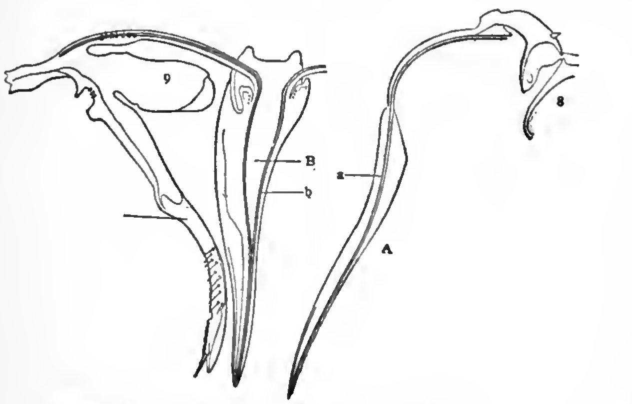
Tenthredinidae (*Hylotoma*)—1, marginal; 2, appendicular; 3, 4, 5, 6, radial or submarginal; 7, 8, 9, median or discoidal; 10, sub-costal; 11, 12, cubital or branchial; and 13, anal or lanceolate cellules; *a*, *b*, *c*, submarginal nervures; *d*, basal nervures; *e*, *f*, recurrent nervures; *st*, stigma; *co*, costa.
2. Cynipidae (*Cynips*).
3. Chalcididae (*Perilampus*).
4. Proctotrypidae (*Codrus*).
5. Mymaridae (*Mymar*).
6. Braconidae (*Bracon*).
7. Ichneumonidae (*Trogus*).
8. Chrysididae (*Cleptes*).
9. Formicidae (*Formica*).
10. Vespidae (*Vespa*).
11. Apidae (*Apathus*).

eyes. The feelers are generally simple in type, rarely showing serrations or prominent appendages; but one or two basal segments are frequently differentiated to form an elongate "scape," the remaining segments—carried at an elbowed angle to the scape—making up the "flagellum"; the segments of the flagellum often bear complex sensory organs. The general characters of the jaws have been mentioned above, and in detail there is great variation in these organs among the different families. The sucking tongue of the Hymenoptera has often been compared with the hypopharynx of other insects. According to D. Sharp, however, the hypopharynx is present in all Hymenoptera as a distinct structure at the base of the "tongue," which must be regarded as representing the fused laciniae of the second maxillae. In the thorax the pronotum and prosternum are closely associated with the mesothorax, but the pleura of the prothorax are usually shifted far forwards, so that the forelegs are inserted just behind the head. A pair of small plates—the tegulae—are very generally present at the bases of the fore-wings. The union of the first abdominal segment with the metathorax has been already mentioned. The second (so-called "first") abdominal segment is often very constricted, forming the "waist" so characteristic of wasps and ants for example. The constriction of this segment and its very perfect articulation with the propodeum give great mobility to the abdomen, so that the ovipositor or sting can be used with the greatest possible accuracy and effect.

Mention has already been made of the series of curved hooks along the costa of the hind-wing; by means of this arrangement the two wings of a side are firmly joined together during flight, which thus becomes particularly accurate. The wings in the Hymenoptera show a marked reduction in the number of nervures as compared with more primitive insects. The main median nervure, and usually also the sub-costal become united with the radial, while the branches of radial, median and cubital nervures pursuing a transverse or recurrent course across the wing, divide its area into a number of areolets or "cells," that are of importance in classification. Among many of the smaller Hymenoptera we find that the wings are almost destitute of nervures. In the hind-wings—on account of their reduced size—the nervures are even more reduced than in the fore-wings.

The legs of Hymenoptera are of the typical insectan form, and the foot is usually composed of five segments. In many families the trochanter appears to be represented by two small segments, there being thus an extra joint in the leg. It is almost certain that the distal of these two segments really belongs to the thigh, but the ordinary nomenclature will be used in the present article, as this character is of great importance in discriminating families, and the two segments in question are referred to the trochanter by most systematic writers.

The typical insectan ovipositor, so well developed among the Hymenoptera, consists of three pairs of processes (gonapophyses) two of which belong to the ninth abdominal segment and one to



After C. Janet, *Aiguillon de la Myrmica rubra* (Paris, 1898).

FIG. 5.—Ovipositor or Sting of Red Ant (*Myrmica rubra*) Queen. Magnified. The right sheath C (outer process of the ninth abdominal segment—9) is shown in connexion with the guide B formed by the inner processes of the 9th segment. The stylet A (process of the 8th abdominal segment—8) is turned over to show its groove *a*, which works along the tongue or rail *b*.

the eighth. The latter are the cutting or piercing stylets (fig. 5, A) of the ovipositor, while the two outer processes of the ninth segment are modified into sheaths or feelers (fig. 5, C) and the two inner processes form a guide (fig. 5, B) on which the stylets work, tongues or rails on the "guide" fitting accurately into longitudinal grooves on the stylet. In the different families of the Hymenoptera, there are various modifications of the ovipositor, in accord with the habits of the insects and the purposes to which the organ is put. The sting of wasps, ants and bees is a modified ovipositor and is used for egg-laying by the fertile females, as well as for defence. Most male Hymenoptera have processes which form claspers or genital armature. These processes are not altogether homologous with those of the ovipositor, being formed by inner and outer lobes of a pair of structures on the ninth abdominal segment.

Many points of interest are to be noted in the internal structure of the Hymenoptera. The gullet leads into a moderate-sized crop, and several pairs of salivary glands open into the mouth. The crop is followed by a proventriculus which, in the higher Hymenoptera, forms the so-called "honey stomach," by the contraction of whose walls the solid and liquid food can be separated, passed on into the digestive stomach, or held in the crop ready for regurgitation into the mouth. Behind the digestive stomach are situated, as usual, intestine and rectum, and the number of kidney (Malpighian) tubes varies from only six to over a hundred, being usually great.

In the female, each ovary consists of a large number of ovarian tubes, in which swollen chambers containing the egg-cells alternate with smaller chambers enclosing nutrient material. In connexion with the ovipositor are two poison-glands, one acid and the other alkaline in its secretion. The acid gland consists of one, two or more tubes, with a cellular coat of several layers, opening into a reservoir whence the duct leads to the exterior. The alkaline gland is an irregular tube with a single cellular layer, its duct opening alongside that of the acid reservoir. These glands are most strongly developed when the ovipositor is modified into a sting.

Development.—Parthenogenesis is of normal occurrence in the life-cycle of many Hymenoptera. There are species of gall-fly in which males are unknown, the unfertilized eggs always developing into females. On the other hand, in certain saw-flies and among the higher families, the unfertilized eggs, capable of development, usually give rise to male insects (see BEE). The larvae of most saw-flies feeding on the leaves of plants are caterpillars (fig. 6, *b*) with numerous abdominal pro-legs, but in most families of Hymenoptera the egg is laid in such a situation that an abundant food-supply is assured without exertion on the part of the larva, which is consequently a legless grub, usually white in colour, and with soft flexible cuticle (fig. 7, *a*). The organs and instincts for egg-laying and food-providing are perhaps the most remarkable features in the economy of the Hymenoptera. Gall-fly grubs are provided with vegetable food through the eggs being laid by the mother insect within plant tissues. The ichneumon pierces the body of a caterpillar and lays her eggs where the grubs will find abundant animal food. A digging-wasp hunts for insect prey and buries it with the egg, while a true wasp feeds her brood with captured insects, as a bird her fledglings. Bees store honey and pollen to serve as food for their young. Thus we find throughout the order a degree of care for offspring unreached by other insects, and this family-life has, in the best known of the Hymenoptera—ants, wasps and bees—developed into an elaborate social organization.

Social Life.—The development of a true insect society among the Hymenoptera is dependent on a differentiation among the females between individuals with well-developed ovaries ("queens") whose special function is reproduction; and individuals with reduced or aborted ovaries ("workers") whose duty is to build the nest, to gather food and to tend and feed the larvae. Among the wasps the workers may only differ from the queens in size, and individuals intermediate between the two forms of female may be met with. Further, the queen wasp, and also the queen humble-bee, commences unaided the work of building and founding a new nest, being afterwards helped by her daughters (the workers) when these have been developed. In the hive-bee and among ants, on the other hand, there are constant structural distinctions between queen and worker, and the function of the queen bee in a hive is confined to egg-laying, the labour of the community being entirely done by the workers. Many ants possess several different forms of worker, adapted for special duties. Details of this fascinating subject are given in the special articles ANT, BEE and WASP (*q.v.*).

Habits and Distribution.—Reference has been already made to the various methods of feeding practised by Hymenoptera in the larval stage, and the care taken of or for the young throughout the order leads in many cases to the gathering of such food by the mother or nurse. Thus, wasps catch flies; worker ants make raids and carry off weak insects of many kinds; bees gather nectar from flowers and transform it into honey within their stomachs—largely for the sake of feeding the larvae in the nest. The feeding habits of the adult may agree with that of the larva, or differ, as in the case of wasps which feed their grubs on flies, but eat principally vegetable food themselves. The nest-building habit is similarly variable. Digging wasps make simple holes in the ground; many burrowing bees form branching tunnels; other bees excavate timber or make their brood-chambers in hollow plant-stems; wasps work up with their saliva vegetable fibres bitten off tree-bark to make paper; social bees produce from glands in their own bodies the wax whence their nest-chambers are built. The inquiline habit ("cuckoo-parasitism"), when one species makes use of the labour of another by invading the nest and laying her eggs there, is of frequent occurrence among Hymenoptera; and in some cases the larva of the intruder is not content with taking the store of food provided, but attacks and devours the larva of the host.

Most Hymenoptera are of moderate or small size, the giants of the order—certain saw-flies and tropical digging-wasps—never reach the bulk attained by the largest beetles, while the wing-spread is narrow compared with that of many dragon-flies and moths. On the other hand, there are thousands of very small species, and the tiny "fairy-flies" (*Mymaridae*), whose larvae live as parasites in the eggs of various insects, are excessively minute for creatures of such complex organization. Hymenoptera are probably less widely distributed than Aptera, Coleoptera or Diptera, but they are to be found in all except the most inhospitable regions of the globe. The order is, with few exceptions, terrestrial or aerial in habit. Comparatively only a few species are, for part of their lives, denizens of fresh water; these, as larvae, are parasitic on the eggs or larvae of other aquatic insects, the little hymenopteron, *Polynema natans*, one of the "fairy-flies"—swims through the water by strokes of her delicate wings in search of a dragon-fly's egg in which to lay her own egg, while the rare *Agriotypus* dives after the case of a caddis-worm. It is of interest that the waters have been invaded by the parasitic group of the Hymenoptera, since in number of species this is by far the largest of the order. No group of terrestrial insects escapes their attacks—even larvae boring in wood are detected by ichneumon flies with excessively long ovipositors. Not a few cases are known in which a parasitic larva is itself pierced by the ovipositor of a "hyperparasite," and even the offspring of the latter may itself fall a victim to the attack of a "tertiary parasite."

Fossil History.—Very little is known of the history of the Hymenoptera previous to the Tertiary epoch, early in which, as we know from the evidence of many Oligocene and Miocene fossils, all the more important families had been differentiated. Fragments of wings from the Lias and Oolitic beds have been referred to ants and bees, but the true nature of these remains is doubtful.

Classification.—Linnaeus divided the Hymenoptera into two sections—the Terebrantia, whose females possess a cutting or piercing ovipositor, and the Aculeata, in which the female organ is modified into a sting. This nomenclature was adopted by P. A. Latreille and has been in general use until the present day. A closely similar division of the order results from T. Hartig's character drawn from the trochanter—whether of two segments or undivided—the groups being termed respectively Ditrocha and Monotrocha. But the most natural division is obtained by the separation of the saw-flies as a primitive sub-order, characterized by the imperfect union of the first abdominal segment with the thorax, and by the broad base of the abdomen, so that there is no median constriction or "waist," and by the presence of thoracic legs—usually also of abdominal pro-legs—in the larva. All the other families of Hymenoptera, including the gall-flies, ichneumons and aculeates, have the first abdominal segment closely united with the thorax, the second abdominal segment constricted so as to form a narrow stalk or "waist," and legless larvae without a hinder outlet to the food-canal. These two sub-orders are usually known as the *Sessiliventra* and *Petioliventra* respectively, but the names *Symphyta* and *Apocrita* proposed in 1867 by C. Gerstaecker have priority, and should not be replaced.

Symphyta.

This sub-order, characterized by the "sessile," broad-based abdomen, whose first segment is imperfectly united with the thorax, and by the usually caterpillar-like larvae with legs, includes the various groups of saw-flies. Three leading families may be mentioned. The *Cephidae*, or stem saw-flies, have an elongate pronotum, a compressed abdomen, and a single spine on the shin of the fore-leg. The soft, white larvae have the thoracic legs very small and feed in the stems of various plants. *Cephus pygmaeus* is a well-known enemy of corn crops. The *Siricidae* ("wood-wasps") are large elongate insects also with one spine on each fore-shin, but with the pronotum closely joined to the mesothorax. The ovipositor is long and prominent, enabling the female insect to lay her eggs in the wood of trees, where the white larvae, whose legs are excessively short, tunnel and feed. These insects are adorned with bands of black and yellow, or with bright metallic colours, and on account of their large size and formidable ovipositors they often cause needless alarm to persons unfamiliar with their habits. The *Tenthredinidae*, or true saw-flies, are distinguished by two spines on each fore-shin, while the larvae are usually caterpillars, with three pairs of thoracic legs, and from six to eight pairs of abdominal pro-legs, the latter not possessing the hooks found on the pro-legs of lepidopterous caterpillars. Most saw-fly larvae devour leaves, and the beautifully serrate processes of the ovipositor are well adapted for egg-laying in plant tissues. Some saw-fly larvae are protected by a slimy secretion (fig. 6, *c*) and a few live concealed in galls. In the form of the feelers, the wing-neuration and minor structural details there is much diversity among the saw-flies. They have been usually regarded as a single family, but W. H. Ashmead has lately differentiated eleven families of them.

Apocrita.

This sub-order includes the vast majority of the Hymenoptera, characterized by the narrowly constricted waist in the adult and by the legless condition of the larva. The trochanter is simple in some genera and divided in others. With regard to the minor divisions of this group, great difference of opinion has prevailed among students. In his recent classification Ashmead (1901) recognizes seventy-nine families arranged under eight "super-families." The number of species included in this division is enormous, and the multiplication of families is, to some extent, a natural result of increasingly close study. But the distinctions between many of these rest on comparatively slight characters, and it is likely that

FIG. 6.—*a*, Pear Saw-fly (*Eriocampoides limacina*); *b*, larva without, and *c*, with its slimy protective coat; *e*, cocoon; *f*, larva before pupation; *g*, pupa, magnified 4 times; *d*, leaves with larvae, natural size.

the future discovery of new genera may abolish many among such distinctions as may now be drawn. It seems advisable, therefore, in the present article to retain the wider conception of the family that has hitherto contented most writers on the Hymenoptera. Ashmead's "super-families" have, however, been adopted as—founded on definite structural characters—they probably indicate relationship more nearly than the older divisions founded mostly on habit. The Cynipoidea include the gall-flies and their parasitic relations. In the Chalcidoidea, Ichneumonoidea and Proctotrypoidea will be found nearly all the "parasitic Hymenoptera" of older classifications. The Formicoidea are the ants. The group of Fossores, or "digging-wasps," is divided by Ashmead, one section forming the Sphecoidea, while the other, together with the Chrysidae

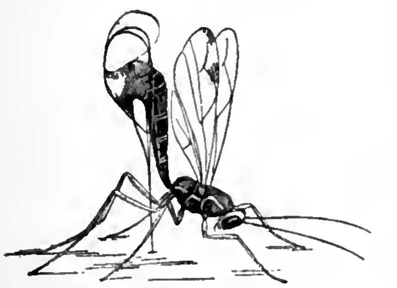
and the true wasps, make up the Vespoidea. The Apoidea consists of the bees only.

Cynipoidea.—In this division the ovipositor issues from the ventral surface of the abdomen; the pronotum reaches back to the tegulae; the trochanter has two segments; the fore-wing (fig. 4, 2) has no stigma, but one or two areolets. The feelers with twelve to fifteen segments are thread-like and straight. All the insects included in this group are small and form two families—the Cynipidae and the Figitidae. They are the "gall-flies," many of the species laying eggs in various plant-tissues where the presence of the larva causes the formation of a pathological growth or gall, always of a definite form and characteristic of the species; the "oak-apple" and the bedeguar of the rose are familiar examples. Other flies of this group have the inquiline habit, laying their eggs in the galls of other species, while others again pierce the cuticle of maggots or aphids, in whose bodies their larvae live as parasites.

Chalcidoidea.—This division resembles the Cynipoidea in the position of the ovipositor, and in the two segmented trochanters. The fore-wing also has no stigma, and the whole wing is almost destitute of nervures and areolets, while the pronotum does not reach back to the tegulae, and the feelers are elbowed (fig. 7). The vast majority of this group, including nearly 5000 known species, are usually reckoned as a single family, the *Chalcididae*, comprising small insects, often of bright metallic colours, whose larvae are parasitic in insects of various orders. The "fig-insects," whose presence in ripening figs is believed essential to the proper development of the fruit, belong to *Blastophaga* and other genera of this family. They are remarkable in having wingless males and winged females. The "polyembryonic" development of an *Encyrtus*, as studied by P. Marchal, is highly remarkable. The female lays her egg in the egg of a small ermine moth (*Hyponomeuta*) and the egg gives rise not to a single embryo but to a hundred, which develop as the host-caterpillar develops, being found at a later stage within the latter enveloped in a flexible tube.

The *Mymaridae* or "fairy-flies" are distinguished from the *Chalcididae* by their narrow fringed wings (figs. 4, 5) and by the situation of the ovipositor just in front of the tip of the abdomen. They are among the most minute of all insects and their larvae are probably all parasitic in insects' eggs.

Ichneumonoidea.—The ten thousand known species included in this group agree with the Cynipoidea and Chalcidoidea in the position of the ovipositor and in the jointed trochanters, but are distinguished by the fore-wing possessing a distinct stigma and usually a typical series of nervures and areolets (figs. 4, 8). Many of the species are of fair size. They lay their eggs (fig. 8) in the bodies of insects and their larvae belonging to various orders. A few small families such as the *Evaniidae* and the *Stephanidae* are included here, but the vast majority of the group fall into two large families, the *Ichneumonidae* and the *Braconidae*, the former distinguished by the presence of two median (or discoidal) cells in the fore-wing (figs. 4, 7), while the latter has only one (figs. 4, 6). Not a few of these insects, however, are entirely wingless. On account of their work in destroying plant-eating insects, the ichneumon-flies are of great economic importance.



After Riley and Howard, *Insect Life*, vol. i.

Fig. 8.—Ichneumon Fly (*Rhyssa persuasoria*) ovipositing.

Proctotrypoidea. — This group may be distinguished from the preceding by the position of the ovipositor at the extreme apex of the abdomen, and from the groups that follow (with very few exceptions) by the jointed trochanters of the legs. The pronotum reaches back to the tegulae. The *Pelecinidae*—included here by Ashmead—are large insects with remarkably elongate abdomens and undivided trochanters. All the other members of the group may be regarded as forming a single family—the *Proctotrypidae*, including an immense number of small parasitic Hymenoptera, not a few of which are wingless. Of special interest are the transformations of *Platygaster*, belonging to this family, discovered by M. Ganin, and familiarized to English readers through the writings of Sir J. Lubbock (Lord Avebury). The first larva is broad in front and tapers behind to a "tail" provided with two divergent processes, so that it resembles a small crustacean. It lives in the grub of a gall-midge and it ultimately becomes changed into the usual white and fleshy hymenopterous larva. The four succeeding sections, in which the ovipositor is modified into a sting (always exserted from the tip of the abdomen) and the trochanters are with few exceptions simple, form the *Aculeata* of Linnaeus.

Formicoidea.—The ants which form this group are readily distinguished by the differentiation of the females into winged "queens" and wingless "workers." The pronotum extends back to the wing-bases, and the "waist" is greatly constricted and marked by one or two "nodes." The differentiation of the females leads to a complex social life, the nesting habits of ants and the various industries that they pursue being of surpassing interest (see Ant).

Vespoidea.—This section includes a number of families characterized by the backward extension of the prothorax to the tegulae and distinguished from the ants by the absence of "nodes" at the base of the abdomen. The true wasps have the fore-wings folded lengthwise when at rest and the fore-legs of normal build—not specialized for digging. The *Vespidae* or social wasps have "queens" and "workers" like the ants, but both these forms of female are winged; the claws on their feet are simple. In the *Eumenidae* or solitary wasps the female sex is undifferentiated, and the foot claws are toothed. (For the habits of these insects see Wasp.) The *Chrysididae* or ruby wasps are small insects with a very hard cuticle exhibiting brilliant metallic colours—blue, green and crimson. Only three or four abdominal segments are visible, the hinder segments being slender and retracted to form a telescope-like tube in which the ovipositor lies. When the ovipositor is brought into use this tube is thrust out. The eggs are laid in the nests of various bees and wasps, the chrysid larva living as a "cuckoo" parasite. The *Trigonalidae*, a small family whose larvae are parasitic in wasps' nests, also probably belong here.

The other families of the *Vespoidea* belong to the series of "Fossores" or digging-wasps. In two of the families—the *Mutillidae* and *Thynnidae*—the females are wingless and the larvae live as parasites in the larvae of other insects; the female *Mutilla* enters humble-bees' nests and lays her eggs in the bee-grubs. In the other families both sexes are winged, and the instinct and industry of the females are among the most wonderful in the Hymenoptera. They make burrows wherein they place insects or spiders which they have caught and stung, laying their eggs beside the victim so that the young larvae find themselves in presence of an abundant and appropriate food-supply. Valuable observations on the habits of these insects are due to J. H. Fabre and G. W. and E. Peckham. The prey is sometimes stung in the neighbourhood of the nerve ganglia, so that it is paralysed but not killed, the grub of the fossorial wasp devouring its victim alive; but this instinct varies in perfection, and in many cases the larva flourishes equally whether its prey be killed or not. The females have a wonderful power of finding their burrows on returning from their hunting expeditions. Among the Vespoid families of fossorial wasps, the *Pompilidae* are the most important. They are recognizable by their slender and elongate hind-legs; many of them provision their burrows with spiders. The *Sapygidae* are parasitic on bees, while the *Scoliidae* are large, robust and hairy insects, many of which prey upon the grubs of chafers.

Sphecoidea.—In this division are included the rest of the "digging-wasps," distinguished from the *Vespoidea* by the short pronotum not reaching backward to the tegulae. They have usually been reckoned as forming a single, very large family—the *Sphegidae*—but ten or twelve subdivisions of the group are regarded as distinct families by Ashmead and others. Great diversity is shown in the details of structure, habits and nature of the prey. Species of *Sphex*, studied by Fabre, provisioned their brood-chambers with crickets. *Pelopoeus* hunts spiders, while *Ammophila* catches caterpillars for the benefit of her young. Fabre states that the last-named insect uses a stone for the temporary closing of her burrow, and the Peckhams have seen a female *Ammophila* take a stone between her mandibles and use it as a hammer for pounding down the earth over her finished nest. The habits of *Bembex* are of especial interest. The female, instead of provisioning her burrow with a supply of food that will suffice the larva for its whole life, brings fresh flies with which she regularly feeds her young. In this instinct we have a correspondence with the habits of social wasps and bees. Yet it may be thought that the usual instinct of the "digging-wasps" to capture and store up food in an underground burrow for the benefit of offspring which they will never see is even more surprising. The habit of some genera is to catch the prey before making their tunnel, but more frequently the insect digs her nest, and then hunts for prey to put into it.

Apoidea.—The bees which make up this group agree with the Sphecoidea in the short pronotum, but may be distinguished from all other Hymenoptera by the widened first tarsal segment and the plumose hairs on head and body. They are usually regarded as forming a single family—the *Apidae*—but there is very great diversity in structural details, and Ashmead divides them into fourteen families. The "tongue," for example, is short and obtuse or emarginate in *Colletes* and *Prosopis*, while in all other bees it is pointed at the tip. But in *Andrena* and its allies it is comparatively short, while in the higher genera, such as *Apis* and *Bombus*, it is elongate and flexible, forming a most elaborate and perfect organ for taking liquid food. Bees feed on honey and pollen. Most of the genera are "solitary" in habit, the female sex being undifferentiated; but among the humble-bees and hive-bees we find, as in social wasps and ants, the occurrence of workers, and the consequent elaboration of a wonderful insect-society. (See Bee.)

Bibliography.—The literature of several special families of the Hymenoptera will be found under the articles Ant, Bee, Ichneumon-Fly, Wasp, &c., referred to above. Among earlier students on structure may be mentioned P. A. Latreille, *Familles naturelles du règne animal* (Paris, 1825), who recognized the nature of the "median segment." C. Gerstaecker (*Arch. f. Naturg.* xx., 1867) and F. Brauer (*Sitzb. K. Akad. Wiss. Wien.* lxxxv., 1883) should also be consulted on this subject. For internal anatomy, specially the digestive organs, see L. Dufour, *Mém. savants étrangers*, vii. (1841), and *Ann. Sci. Nat. Zool.* (4), i. 1854. For nervous system H. Viallanes, *Ann. Sci. Nat. Zool.* (7), ii. iv. 1886–1887, and F. C. Kenyon, *Journ. Comp. Neurol.* vi., 1896. For poison and other glands, see L. Bordas, *Ann. Sci. Nat. Zool.* (7) xix., 1895. For the sting and ovipositor H. Dewitz, *Zeits. wiss. Zool.* xxv., 1874, xxviii., 1877, and E. Zander, *ib.* lxvi., 1899. For male genital armature S. A. Peytoureau, *Morphologie de l'armure génitale des* *insectes* (Bordeaux, 1895), and E. Zander, *Zeits. wiss. Zool.* lxvii., 1900. The systematic student of Hymenoptera is greatly helped by C. G. de Dalla Torre's *Catalogus Hymenopterorum* (10 vols., Leipzig, 1893–1902). For general classifications see F. W. Konow, *Entom. Nachtr.* (1897), and W. H. Ashmead, *Proc. U.S. Nat. Mus.* xxiii., 1901; the latter paper deals also especially with the Ichneumonoidea of the globe. For habits and life histories of Hymenoptera see J. Lubbock (Lord Avebury), *Ants, Bees and Wasps* (9th ed., London, 1889); C. Janet, *Études sur les fourmis, les guêpes et les abeilles* (Paris, &c., 1893 and onwards); and G. W. and E. G. Peckham, *Instincts and Habits of Solitary Wasps* (Madison, Wis. U.S.A., 1898). Monographs of most of the families of British Hymenoptera have now been published. For saw-flies and gall-flies, see P. Cameron's *British Phytophagous Hymenoptera* (4 vols., London, *Ray Soc.*, 1882–1893). For Ichneumonoidea, C. Morley's *Ichneumons of Great Britain* (Plymouth, 1903, &c.), and T. A. Marshall's "British Braconidae," *Trans. Entom. Soc.*, 1885–1899. The smaller parasitic Hymenoptera have been neglected in this country since A. H. Haliday's classical papers *Entom. Mag.* i.-v., 1833–1838) but Ashmead's "North American Proctotrypidae" (*Bull. U.S. Nat. Mus.* xlv., 1893) is valuable for the European student. For the Fossores, wasps, ants and bees see E. Saunders, *Hymenoptera Aculeata of the British Islands* (London, 1896). Exhaustive references to general systematic works will be found in de Dalla Torre's *Catalogue* mentioned above. Of special value to English students are C. T. Bingham's *Fauna of British India*, "Hymenoptera" (London, 1897 and onwards), and P. Cameron's volumes on Hymenoptera in the *Biologia Centrali-Americana*. F. Smith's *Catalogues of Hymenoptera in the British Museum* (London, 1853–1859) are well worthy of study. (G. H. C.)

HYMETTUS (Ital. Monte Matto, hence the modern name Trello Vouni), a mountain in Attica, bounding the Athenian plain on the S.E. Height, 3370 ft. It was famous in ancient times for its bees, which gathered honey of peculiar flavour from its aromatic herbs; their fame still persists. The spring mentioned by Ovid (*Ars Amat.* iii. 687) is probably to be recognized near the monastery of Syriani or Kaesariani on the western slope. This may be identical with that known as Κύλλου Πήρα, said to be a remedy for barrenness in women. The marble of Hymettus, which often has a bluish tinge, was used extensively for building in ancient Athens, and also, in early times, for sculpture; but the white marble of Pentelicus was preferred for both purposes.

See E. Dodwell, *Classical and Topographical Tour* (1819), i. 483.

HYMNS.— 1. *Classical Hymnody.*— The word "hymn" (ὕμνος) was employed by the ancient Greeks[1] to signify a song or poem composed in honour of gods, heroes or famous men, or to be recited on some joyful, mournful or solemn occasion. Polymnia was the name of their lyric muse. Homer makes Alcinous entertain Odysseus with a "hymn" of the minstrel Demodocus, on the capture of Troy by the wooden horse. The *Works and Days* of Hesiod begins with an invocation to the Muses to address hymns to Zeus, and in his *Theogonia* he speaks of them as singing or inspiring "hymns" to all the divinities, and of the bard as "their servant, hymning the glories of men of old, and of the gods of Olympus." Pindar calls by this name odes, like his own, in praise of conquerors at the public games of Greece. The Athenian dramatists (Euripides most frequently) use the word and its cognate verbs in a similar manner; they also describe by them metrical oracles and apophthegms, martial, festal and hymeneal songs, dirges and lamentations or incantations of woe.

Hellenic hymns, according to this conception of them, have come down to us, some from a very early and others from a late period of Greek classical literature. Those which passed by the name of Homer[2] were already old in the time of Thucydides. They are mythological poems (several of them long), in hexameter verse—some very interesting. That to Apollo contains a traditionary history of the origin and progress of the Delphic worship; those on Hermes and on Dionysus are marked by much liveliness and poetical fancy. Hymns of a like general character, but of less interest (though these also embody some fine poetical traditions of the Greek mythology, such as the story of Teiresias, and that of the wanderings of Leto), were written in the 3rd century before Christ, by Callimachus of Cyrene. Cleanthes, the successor of Zeno, composed (also in hexameters) an "excellent and devout hymn" (as it is justly called by Cudworth, in his *Intellectual System*) to Zeus, which is preserved in the *Eclogae* of Stobaeus, and from which Aratus borrowed the words, "For we are also His offspring," quoted by St Paul at Athens. The so-called Orphic hymns, in hexameter verse, styled τελεταί, or hymns of initiation into the "mysteries" of the Hellenic religion, are productions of the Alexandrian school, —as to which learned men are not agreed whether they are earlier or later than the Christian era.

[1] The history of the "hymn" naturally begins with Greece, but it may be found in some form much earlier; Assyria and Egypt have left specimens, while India has the Vedic hymns, and Confucius collected "praise songs" in China.

[2] See GREEK LITERATURE.

The Romans did not adopt the word "hymn"; nor have we many Latin poems of the classical age to which it can properly be applied. There are, however, a few—such as the simple and graceful "Dianae sumus in fide" ("Dian's votaries are we") of Catullus, and "Dianam tenerae dicite virgines" ("Sing to Dian, gentle maidens") of Horace—which approach much more nearly than anything Hellenic to the form and character of modern hymnody.

2. *Hebrew Hymnody.*—For the origin and idea of Christian hymnody we must look, not to Gentile, but to Hebrew sources. St Augustine's definition of a hymn, generally accepted by Christian antiquity, may be summed up in the words, "praise to God with song" ("cum cantico"); Bede understood the "canticum" as properly requiring metre; though he thought that what in its original language was a true hymn might retain that character in an unmetrical translation. Modern use has enlarged the definition; Roman Catholic writers extend it to the praises of saints; and the word now comprehends rhythmical prose as well as verse, and prayer and spiritual meditation as well as praise.

The modern distinction between psalms and hymns is arbitrary (see PSALMS). The former word was used by the LXX. as a generic designation, probably because it implied an accompaniment by the psaltery (said by Eusebius to have been of very ancient use in the East) or other instruments. The cognate verb "psallere" has been constantly applied to hymns, both in the Eastern and in the Western Church; and the same compositions which they described generically as "psalms" were also called by the LXX. "odes" (*i.e.* songs) and "hymns." The latter word occurs, *e.g.* in Ps. lxxii. 20 ("the hymns of David the son of Jesse"), in Ps. lxv. 1, and also in the Greek titles of the 6th, 54th, 55th, 67th and 76th (this numbering of the psalms being that of the English version, not of the LXX.). The 44th chapter of Ecclesiasticus, "Let us now praise famous men," &c., is entitled in the Greek πατέρων ὕμνος, "The Fathers' Hymn." Bede speaks of the whole book of Psalms as called "liber hymnorum," by the universal consent of Hebrews, Greeks and Latins.

In the New Testament we find our Lord and His apostles singing a hymn (ὑμνήσαντες ἐξῆλθον), after the institution of the Lord's Supper; St Paul and Silas doing the same (ὕμνουν τὸν θεόν) in their prison at Philippi; St James recommending psalm-singing (ψαλλέτω), and St Paul "psalms and hymns and spiritual songs" (ψαλμοῖς καὶ ὕμνοις καὶ ᾠδαῖς πνευματικαῖς) St Paul also, in the 14th chapter of the first epistle to the Corinthians, speaks of singing (ψαλῶ) and of every man's psalm (ἕκαστος ὑμῶν ψαλμὸν ἔχει), in a context which plainly has reference to the assemblies of the Corinthian Christians for common worship. All the words thus used were applied by the LXX. to the Davidical psalms; it is therefore possible that these only may be intended, in the different places to which we have referred. But there are in St Paul's epistles several passages (Eph. v. 14; 1 Tim. iii. 16; 1 Tim. vi. 15, 16; 2 Tim. ii. 11,12) which have so much of the form and character of later Oriental hymnody as to have been supposed by Michaelis and others to be extracts from original hymns of the Apostolic age. Two of them are apparently introduced as quotations, though not found elsewhere in the Scriptures. A third has not only rhythm, but rhyme. The thanksgiving prayer of the assembled disciples, recorded in Acts iv., is both in substance and in manner poetical;

and in the canticles, "Magnificat," "Benedictus," &c., which manifestly followed the form and style of Hebrew poetry, hymns or songs, proper for liturgical use, have always been recognized by the church.

3. *Eastern Church Hymnody.*—The hymn of our Lord, the precepts of the apostles, the angelic song at the nativity, and "Benedicite omnia opera" are referred to in a curious metrical prologue to the hymnary of the Mozarabic Breviary as precedents for the practice of the Western Church. In this respect, however, the Western Church followed the Eastern, in which hymnody prevailed from the earliest times.

Therapeutae.

Philo describes the Theraputae (*q.v.*) of the neighbourhood of Alexandria as composers of original hymns, which (as well as old) were sung at their great religious festivals—the people listening in silence till they came to the closing strains, or refrains, at the end of a hymn or stanza (the "acroteleutia" and "ephymnia"), in which all, women as well as men, heartily joined. These songs, he says, were in various metres (for which he uses a number of technical terms); some were choral, some not; and they were divided into variously constructed strophes or stanzas. Eusebius, who thought that the Theraputae were communities of Christians, says that the Christian practice of his own day was in exact accordance with this description.

Antiphonal singing.

The practice, not only of singing hymns, but of singing them antiphonally, appears, from the well-known letter of Pliny to Trajan, to have been established in the Bithynian churches at the beginning of the 2nd century. They were accustomed "stato die ante lucem convenire, carmenque Christo, quasi Deo, dicere *secum invicem.*" This agrees well, in point of time, with the tradition recorded by the historian Socrates, that Ignatius (who suffered martyrdom about A.D. 107) was led by a vision or dream of angels singing hymns in that manner to the Holy Trinity to introduce antiphonal singing into the church of Antioch, from which it quickly spread to other churches. There seems to be an allusion to choral singing in the epistle of Ignatius himself to the Romans, where he exhorts them, "χορὸς γενόμενοι" ("having formed themselves into a choir"), to "sing praise to the Father in Christ Jesus." A statement of Theodoret has sometimes been supposed to refer the origin of antiphonal singing to a much later date; but this seems to relate only to the singing of Old Testament Psalms (τὴν Δαυιδικὴν μελῳδίαν), the alternate chanting of which, by a choir divided into two parts, was (according to that statement) first introduced into the church of Antioch by two monks famous in the history of their time, Flavianus and Diodorus, under the emperor Constantius II.

2nd century.

Other evidence of the use of hymns in the 2nd century is contained in a fragment of Caius, preserved by Eusebius, which refers to "all the psalms and odes written by faithful brethren from the beginning," as "hymning Christ, the Word of God, as God." Tertullian also, in his description of the "Agapae," or love-feasts, of his day, says that, after washing hands and bringing in lights, each man was invited to come forward and sing to God's praise something either taken from the Scriptures or of his own composition ("ut quisque de Sacris Scripturis vel proprio ingenio potest"). George Bull, bishop of St David's, believed one of those primitive compositions to be the hymn appended by Clement of Alexandria to his *Paedagogus*; and Archbishop Ussher considered the ancient morning and evening hymns, of which the use was enjoined by the *Apostolical Constitutions*, and which are also mentioned in the "Tract on Virginity" printed with the works of St Athanasius, and in St Basil's treatise upon the Holy Spirit, to belong to the same family. Clement's hymn, in a short anapaestic metre, beginning στόμιον πώλων ἀδαῶν (or, according to some editions, βασιλεῦ ἁγίων, λόγε πανδαμάτωρ—translated by the Rev. A. Chatfield, "O Thou, the King of Saints, all-conquering Word"), is rapid, spirited and well-adapted for singing. The Greek "Morning Hymn" (which, as divided into verses by Archbishop Ussher in his treatise *De Symbolis*, has a majestic rhythm, resembling a choric or dithyrambic strophe) is the original form of "Gloria in Excelsis," still said or sung, with some variations, in all branches of the church which have not relinquished the use of liturgies. The Latin form of this hymn (of which that in the English communion office is an exact translation) is said, by Bede and other ancient writers, to have been brought into use at Rome by Pope Telesphorus, as early as the time of the emperor Hadrian. A third, the Vesper or "Lamp-lighting" hymn ("φῶς ἱλαρὸν ἁγίας δόξης"—translated by Canon Bright "Light of Gladness, Beam Divine"), holds its place to this day in the services of the Greek rite.

3rd century.

In the 3rd century Origen seems to have had in his mind the words of some other hymns or hymn of like character, when he says (in his treatise *Against Celsus*): "We glorify in hymns God and His only begotten Son; as do also the Sun, the Moon, the Stars and all the host of heaven. All these, in one Divine chorus, with the just among men, glorify in hymns God who is over all, and His only begotten Son." So highly were these compositions esteemed in the Syrian churches that the council which deposed Paul of Samosata from the see of Antioch in the time of Aurelian justified that act, in its synodical letter to the bishops of Rome and Alexandria, on this ground (among others) that he had prohibited the use of hymns of that kind, by uninspired writers, addressed to Christ.

After the conversion of Constantine, the progress of hymnody became closely connected with church controversies. There had been in Edessa, at the end of the 2nd or early in the 3rd century, a Gnostic writer of conspicuous ability, named Bardesanes, who was succeeded, as the head of his sect or school, by his son Harmonius. Both father and son wrote hymns, and set them to agreeable melodies, which acquired, and in the 4th century still retained, much local popularity. Ephraem Syrus, the first voluminous hymn-writer whose works remain to us, thinking that the same melodies might be made useful to the faith, if adapted to more orthodox words, composed to them a large number of hymns in the Syriac language, principally in tetrasyllabic, pentasyllabic and heptasyllabic metres, divided into strophes of from 4 to 12,16 and even 20 lines each. When a strophe contained five lines, the fifth was generally an "ephymnium," detached in sense, and consisting of a prayer, invocation, doxology or the like, to be sung antiphonally, either in full chorus or by a separate part of the choir. The *Syriac Chrestomathy* of August Hahn (Leipzig, 1825), and the third volume of H. A. Daniel's *Thesaurus Hymnologicus* (Leipzig, 1841–1856), contain specimens of these hymns. Some of them have been translated into (unmetrical) English by the Rev. Henry Burgess (*Select Metrical Hymns of Ephrem Syrus*, &c., 1853). A considerable number of those so translated are on subjects connected with death, resurrection, judgment, &c., and display not only Christian faith and hope, but much simplicity and tenderness of natural feeling. Theodoret speaks of the spiritual songs of Ephraem as very sweet and profitable, and as adding much, in his (Theodoret's) time, to the brightness of the commemorations of martyrs in the Syrian Church.

The Greek hymnody contemporary with Ephraem followed, with some licence, classical models. One of its favourite metres was the Anacreontic; but it also made use of the short anapaestic, Ionic, iambic and other lyrical measures, as well as the hexameter and pentameter. Its principal authors were Methodius, bishop of Olympus, who died about A.D. 311, Synesius, who became bishop of Ptolemais in Cyrenaica in 410, and Gregory Nazianzen, for a short time (380-381) patriarch of Constantinople. The merits of these writers have been perhaps too much depreciated by the admirers of the later Greek "Melodists." They have found an able English translator in the Rev. Allen Chatfield (*Songs and Hymns of Earliest Greek Christian Poets*, London, 1876). Among the most striking of their works are μνώεο Χριστέ ("Lord Jesus, think of me"), by Synesius; σὲ τὸν ἄφθιτον μονάρχην ("O Thou, the One Supreme") and τί σοι θέλεις γενέσθαι ("O soul of mine, repining"), by Gregory; also ἄνωθεν παρθένοι ("The Bridegroom cometh"), by Methodius. There continued to be Greek metrical hymn-writers, in a similar style, till a much later date. Sophronius, patriarch of Jerusalem in the 7th century, wrote seven Anacreontic hymns; and St John Damascene, one of the most copious of the second school of "Melodists," was also the author of some long compositions in trimeter iambics.

An important development of hymnody at Constantinople arose out of the Arian controversy. Early in the 4th century Athanasius had rebuked, not only the doctrine of Arius, but the light character of certain hymns by which he endeavoured to make that doctrine popular. When, towards the close of that century (398), St John Chrysostom was raised to the metropolitan see, the Arians, who were still numerous at Constantinople, had no places of worship within the walls; but they were in the habit of coming into the city at sunset on Saturdays, Sundays and the greater festivals, and congregating in the porticoes and other places of public resort, where they sung, all night through, antiphonal songs, with "acroteleutia" (closing strains, or refrains), expressive of Arian doctrine, often accompanied by taunts and insults to the orthodox. Chrysostom was apprehensive that this music might draw some of the simpler church people to the Arian side; he therefore organized, in opposition to it, under the patronage and at the cost of Eudoxia, the empress of Arcadius (then his friend), a system of nightly processional hymn-singing, with silver crosses, wax-lights and other circumstances of ceremonial pomp. Riots followed, with bloodshed on both sides, and with some personal injury to the empress's chief eunuch, who seems to have officiated as conductor or director of the church musicians. This led to the suppression, by an imperial edict, of all public Arian singing; while in the church the practice of nocturnal hymn-singing on certain solemn occasions, thus first introduced, remained an established institution.

Period of Arian controversy.

It is not improbable that some rudiments of the peculiar system of hymnody which now prevails throughout the Greek communion, and whose affinities are rather to the Hebrew and Syriac than to the classical forms, may have existed in the church of Constantinople, even at that time. Anatolius, patriarch of Constantinople in the middle of the 5th century, was the precursor of that system; but the reputation of being its proper founder belongs to Romanos, of whom little more is known than that he wrote hymns still extant, and lived towards the end of that century. The importance of that system in the services of the Greek church may be understood from the fact that Dr J. M. Neale computed four-fifths of the whole space (about 5000 pages) contained in the different service-books of that church to be occupied by hymnody, all in a language or dialect which has ceased to be anywhere spoken.

Greek system of hymnody.

The system has a peculiar technical terminology, in which the words "troparion," "ode," "canon" and "hirmus" (εἶρμος) chiefly require explanation.

The *troparion* is the unit of the system, being a strophe or stanza, seen, when analysed, to be divisible into verses or clauses, with regulated caesuras, but printed in the books as a single prose sentence, without marking any divisions. The following (turned into English, from a "canon" by John Mauropus) may be taken as an example: "The never-sleeping Guardian, | the patron of my soul, | the guide of my life, | allotted me by God, | I hymn thee, Divine Angel | of Almighty God." Dr Neale and most other writers regard all these "troparia" as rhythmical or modulated prose. Cardinal J. B. Pitra, on the other hand, who in 1867 and 1876 published two learned works on this subject, maintains that they are really metrical, and governed by definite rules of prosody, of which he lays down sixteen. According to him, each "troparion" contains from three to thirty-three verses; each verse varies from two to thirteen syllables, often in a continuous series, uniform, alternate or reciprocal, the metre being always syllabic, and depending, not on the quantity of vowels or the position of consonants, but on an harmonic series of accents.

In various parts of the services solitary troparia are sung, under various names, "contacion," "oecos," "cathisma," &c., which mark distinctions either in their character or in their use.

An *ode* is a song or hymn compounded of several similar "troparia,"—usually three, four or five. To these is always prefixed a typical or standard "troparion," called the *hirmus*, by which the syllabic measure, the periodic series of accents, and in fact the whole structure and rhythm of the stanzas which follow it are regulated. Each succeeding "troparion" in the same "ode" contains the same number of verses, and of syllables in each verse, and similar accents on the same or equivalent syllables. The "hirmus" may either form the first stanza of the "ode" itself, or (as is more frequently the case) may be taken from some other piece; and, when so taken, it is often indicated by initial words only, without being printed at length. It is generally printed within commas, after the proper rubric of the "ode." A hymn in irregular "stichera" or stanzas, without a "hirmus," is called "idiomelon." A system of three or four odes is "triodion" or "tetraodion."

A *canon* is a system of eight (theoretically nine) connected odes, the second being always suppressed. Various pauses, relieved by the interposition of other short chants or readings, occur during the singing of a whole "canon." The final "troparion" in each ode of the series is not unfrequently detached in sense (like the "ephymnia" of Ephraem Syrus), particularly when it is in the (very common) form of a "theotokion," or ascription of praise to the mother of our Lord, and when it is a recurring refrain or burden.

There were two principal periods of Greek hymnography constructed on these principles—the first that of Romanos and his followers, extending over the 6th and 7th centuries, the second that of the schools which arose during the Iconoclastic controversy in the 8th century, and which continued for some centuries afterwards, until the art itself died out.

The works of the writers of the former period were collected in *Tropologia*, or church hymn-books, which were held in high esteem till the 10th century, when they ceased to be regarded as church-books, and so fell into neglect. They are now preserved only in a very small number of manuscripts. From three of these, belonging to public libraries at Moscow, Turin and Rome, Cardinal Pitra has printed, in his *Analecta*, a number of interesting examples, the existence of which appears to have been unknown to Dr Neale, and which, in the cardinal's estimation, are in many respects superior to the "canons," &c., of the modern Greek service-books, from which all Neale's translations (except some from Anatolius) are taken. Cardinal Pitra's selections include twenty-nine works by Romanos, and some by Sergius, and nine other known, as well as some unknown, authors. He describes them as having generally a more dramatic character than the "melodies" of the later period, and a much more animated style; and he supposes that they may have been originally sung with dramatic accompaniments, by way of substitution for the theatrical performances of Pagan times. As an instance of their peculiar character, he mentions a Christmas or Epiphany hymn by Romanos, in twenty-five long strophes, in which there is, first, an account of the Nativity and its accompanying wonders, and then a dialogue between the wise men, the Virgin mother and Joseph. The magi arrive, are admitted, describe the moral and religious condition of Persia and the East, and the cause and adventures of their journey, and then offer their gifts. The Virgin intercedes for them with her Son, instructs them in some parts of Jewish history, and ends with a prayer for the salvation of the world.

School of Romanos.

The controversies and persecutions of the 8th and succeeding centuries turned the thoughts of the "melodists" of the great monasteries of the Studium at Constantinople and St Saba in Palestine and their followers, and those of the adherents of the Greek rite in Sicily and South Italy (who suffered much from the Saracens and the Normans), into a less picturesque but more strictly theological course; and the influence of those controversies, in which the final success of the cause of "Icons" was largely due to the hymns, as well as to the courage and sufferings, of these confessors, was probably the cause of their supplanting, as they did, the works of the older school. Cardinal Pitra gives them the praise of having discovered a graver and more solemn style of chant, and of having done much to fix the dogmatic theology of their church upon its present lines of near approach to the Roman.

Melodists.

Among the "melodists" of this latter Greek school there were many saints of the Greek church, several patriarchs and two emperors—Leo the Philosopher, and Constantine Porphyrogenitus, his son. Their greatest poets were Theodore and Joseph of the Studium, and Cosmas and John (called Damascene) of St Saba. Neale translated into English verse several selected portions, or centoes, from the works of these and others, together with four selections from earlier works by

Anatolius. Some of his translations—particularly "The day is past and over," from Anatolius, and "Christian, dost thou see them," from Andrew of Crete—have been adopted into hymn-books used in many English churches; and the hymn "Art thou weary," which is rather founded upon than translated from one by Stephen the Sabaite, has obtained still more general popularity.

4. *Western Church Hymnody.*—It was not till the 4th century that Greek hymnody was imitated in the West, where its introduction was due to two great lights of the Latin Church—St Hilary of Poitiers and St Ambrose of Milan.

Hilary was banished from his see of Poitiers in 356, and was absent from it for about four years, which he spent in Asia Minor, taking part during that time in one of the councils of the Eastern Church. He thus had full opportunity of becoming acquainted with the Greek church music of that day; and he wrote (as St Jerome, who was thirty years old when Hilary died, and who was well acquainted with his acts and writings, and spent some time in or near his diocese, informs us) a "book of hymns," to one of which Jerome particularly refers, in the preface to the second book of his own commentary on the epistle to the Galatians. Isidore, archbishop of Seville, who presided over the fourth council of Toledo, in his book on the offices of the church, speaks of Hilary as the first Latin hymn-writer; that council itself, in its 13th canon, and the prologue to the Mozarabic hymnary (which is little more than a versification of the canon), associate his name, in this respect, with that of Ambrose. A tradition, ancient and widely spread, ascribed to him the authorship of the remarkable "Hymnum dicat turba fratrum, hymnum cantus personet" ("Band of brethren, raise the hymn, let your song the hymn resound"), which is a succinct narrative, in hymnal form, of the whole gospel history; and is perhaps the earliest example of a strictly didactic hymn. Both Bede and Hincmar much admired this composition, though the former does not mention, in connexion with it, the name of Hilary. The private use of hymns of such a character by Christians in the West may probably have preceded their ecclesiastical use; for Jerome says that in his day those who went into the fields might hear "the ploughman at his hallelujahs, the mower at his hymns, and the vine-dresser singing David's psalms." Besides this, seven shorter metrical hymns attributed to Hilary are still extant.

Of the part taken by Ambrose, not long after Hilary's death, in bringing the use of hymns into the church of Milan, we have a contemporary account from his convert, St Augustine. Justina, mother of the emperor Valentinian, favoured the Arians, and desired to remove Ambrose from his see. The "devout people," of whom Augustine's mother, Monica, was one, combined to protect him, and kept guard in the church. "Then," says Augustine, "it was first appointed that, after the manner of the Eastern churches, hymns and psalms should be sung, lest the people should grow weary and faint through sorrow; which custom has ever since been retained, and has been followed by almost all congregations in other parts of the world." He describes himself as moved to tears by the sweetness of these "hymns and canticles":—"The voices flowed into my ears; the truth distilled into my heart; I overflowed with devout affections, and was happy." To this time, according to an uncertain but not improbable tradition which ascribed the composition of the "Te Deum" to Ambrose, and connected it with the conversion of Augustine, is to be referred the commencement of the use in the church of that sublime unmetrical hymn.

Ambrose.

It is not, however, to be assumed that the hymnody thus introduced by Ambrose was from the first used according to the precise order and method of the later Western ritual. To bring it into (substantially) that order and method appears to have been the work of St Benedict. Walafrid Strabo, the earliest ecclesiastical writer on this subject (who lived at the beginning of the 9th century), says that Benedict, on the constitution of the religious order known by his name (about 530), appointed the Ambrosian hymns to be regularly sung in his offices for the canonical hours. Hence probably originated the practice of the Italian churches, and of others which followed their example, to sing certain hymns (Ambrosian, or by the early successors of the Ambrosian school) daily throughout the week, at "Vespers," "Lauds" and "Nocturns," and on some days at "Compline" also—varying them with the different ecclesiastical seasons and festivals, commemorations of saints and martyrs and other special offices. Different dioceses and religious houses had their own peculiarities of ritual, including such hymns as were approved by their several bishops or ecclesiastical superiors, varying in detail, but all following the same general method. The national rituals, which were first reduced into a form substantially like that which has since prevailed, were probably those of Lombardy and of Spain, now known as the "Ambrosian" and the "Mozarabic." The age and origin of the Spanish ritual are uncertain, but it is mentioned in the 7th century by Isidore, bishop of Seville. It contained a copious hymnary, the original form of which may be regarded as canonically approved by the fourth council of Toledo (633). By the 13th canon of that council, an opinion (which even then found advocates) against the use in churches of any hymns not taken from the Scriptures—apparently the same opinion which had been held by Paul of Samosata—was censured; and it was ordered that such hymns should be used in the Spanish as well as in the Gallican churches, the penalty of excommunication being denounced against all who might presume to reject them.

The hymns of which the use was thus established and authorized were those which entered into the daily and other offices of the church, afterwards collected in the "Breviaries"; in which the hymns "proper" for "the week," and for "the season," continued for many centuries, with very few exceptions, to be derived from the earliest epoch of Latin Church poetry—reckoning that epoch as extending from Hilary and Ambrose to the end of the pontificate of Gregory the Great. The "Ambrosian" music, to which those hymns were generally sung down to the time of Gregory, was more popular and congregational than the "Gregorian," which then came into use, and afterwards prevailed. In the service of the mass it was not the general practice, before the invention of sequences in the 9th century, to sing any hymns, except some from the Scriptures esteemed canonical, such as the "Song of the Three Children" ("Benedicite omnia opera"). But to this rule there were, according to Walafrid Strabo, some occasional exceptions; particularly in the case of Paulinus, patriarch of Aquileia under Charlemagne, himself a hymn-writer, who frequently used hymns, composed by himself or others, in the eucharistic office, especially in private masses.

Some of the hymns called "Ambrosian" (nearly 100 in number) are beyond all question by Ambrose himself, and the rest probably belong to his time or to the following century. Four, those beginning "Aeterne rerum conditor" ("Dread Framer of the earth and sky"), "Deus Creator omnium" ("Maker of all things, glorious God"), "Veni Redemptor Gentium" ("Redeemer of the nations, come") and "Jam surgit hora tertia" ("Christ at this hour was crucified"), are quoted as works of Ambrose by Augustine. These, and others by the hand of the same master, have the qualities most valuable in hymns intended for congregational use. They are short and complete in themselves; easy, and at the same time elevated in their expression and rhythm; terse and masculine in thought and language; and (though sometimes criticized as deficient in theological precision) simple, pure and not technical in their rendering of the great facts and doctrines of Christianity, which they present in an objective and not a subjective manner. They have exercised a powerful influence, direct or indirect, upon many of the best works of the same kind in all succeeding generations. With the Ambrosian hymns are properly classed those of Hilary, and the contemporary works of Pope Damasus I. (who wrote two hymns in commemoration of saints), and of Prudentius, from whose *Cathemerina* ("Daily Devotions") and *Peristephana* ("Crown-songs for Martyrs"), all poems of considerable, some of great length—about twenty-eight hymns, found in various Breviaries, were derived. Prudentius was a layman, a native of Saragossa, and it was in the Spanish ritual that his hymns were most largely used. In the Mozarabic Breviary almost the whole of one of his finest poems (from which most churches took one part only, beginning "Corde natus ex parentis") was appointed to be sung between Easter and Ascension-Day, being divided into eight or nine hymns; and on some of the commemorations of Spanish saints long poems from his *Peristephana* were recited or sung at large. He is entitled to a high rank among Christian poets, many of the hymns taken from his works being full of fervour and sweetness, and by no means deficient in dignity or strength.

5th and 6th centuries. These writers were followed in the 5th and early in the 6th century by the priest Sedulius, whose reputation perhaps exceeded his merit; Elpis, a noble Roman lady (considered, by an erroneous tradition, to have been the wife of the philosophic statesman Boetius); Pope Gelasius I.; and Ennodius, bishop of Pavia. Sedulius and Elpis wrote very little from which hymns could be extracted; but the small number taken from their compositions obtained wide popularity, and have since held their ground. Gelasius was of no great account as a hymn-writer; and the works of Ennodius appear to have been known only in Italy and Spain. The latter part of the 6th century produced Pope Gregory the Great and Venantius Fortunatus, an Italian poet, the friend of Gregory, and the favourite of Radegunda, queen of the Franks, who died (609) bishop of Poitiers. Eleven hymns of Gregory, and twelve or thirteen (mostly taken from longer poems) by Fortunatus, came into general use in the Italian, Gallican and British churches. Those of Gregory are in a style hardly distinguishable from the Ambrosian; those of Fortunatus are graceful, and sometimes vigorous. He does not, however, deserve the praise given to him by Dr Neale, of having struck out a new path in Latin hymnody. On the contrary, he may more justly be described as a disciple of the school of Prudentius, and as having affected the classical style, at least as much as any of his predecessors.

The poets of this primitive epoch, which closed with the 6th century, wrote in the old classical metres, and made use of a considerable variety of them—anapaestic, anacreontic, hendecasyllabic, asclepiad, hexameters and pentameters and others. Gregory and some of the Ambrosian authors occasionally wrote in sapphics; but the most frequent measure was the iambic dimeter, and, next to that, the trochaic. The full alcaic stanza does not appear to have been used for church purposes before the 16th century, though some of its elements were. In the greater number of these works, a general intention to conform to the rules of Roman prosody is manifest; but even those writers (like Prudentius) in whom that conformity was most decided allowed themselves much liberty of deviation from it. Other works, including some of the very earliest, and some of conspicuous merit, were of the kind described by Bede as not metrical but "rhythmical"—*i.e.*(as he explains the term "rhythm"), "modulated to the ear in imitation of different metres." It would be more correct to call them metrical—(*e.g.* still trochaic or iambic, &c., but, according to new laws of syllabic quantity, depending entirely on accent, and not on the power of vowels or the position of consonants)—laws by which the future prosody of all modern European nations was to be governed. There are also, in the hymns of the primitive period (even in those of Ambrose), anticipations—irregular indeed and inconstant, but certainly not accidental—of another great innovation, destined to receive important developments, that of assonance or rhyme, in the final letters or syllables of verses. Archbishop Trench, in the introduction to his *Sacred Latin Poetry*, has traced the whole course of the transition from the ancient to the modern forms of versification, ascribing it to natural and necessary causes, which made such changes needful for the due development of the new forms of spiritual and intellectual life, consequent upon the conversion of the Latin-speaking nations to Christianity.

6th century downwards. From the 6th century downwards we see this transformation making continual progress, each nation of Western Christendom adding, from time to time, to the earlier hymns in its service-books others of more recent and frequently of local origin. For these additions, the commemorations of saints, &c., as to which the devotion of one place often differed from that of another, offered especial opportunities. This process, while it promoted the development of a medieval as distinct from the primitive style, led also to much deterioration in the quality of hymns, of which, perhaps, some of the strongest examples may be found in a volume published in 1865 by the Irish Archaeological Society from a manuscript in the library of Trinity College, Dublin. It contains a number of hymns by Irish saints of the 6th, 7th and 8th centuries—in several instances fully rhymed, and in one mixing Erse and Latin barbarously together, as was not uncommon, at a much later date, in semi-vernacular hymns of other countries. The Mozarabic Breviary, and the collection of hymns used in the Anglo-Saxon churches, published in 1851 by the Surtees Society (chiefly from a Benedictine MS. in the college library of Durham, supplemented by other MSS. in the British Museum), supply many further illustrations of the same decline of taste:—such sapphics, *e.g.*, as the "Festum insigne prodiit coruscum" of Isidore, and the "O veneranda Trinitas laudanda" of the Anglo-Saxon books. The early medieval period, however, from the time of Gregory the Great to that of Hildebrand, was far from deficient in the production of good hymns, wherever learning flourished. Bede in England, and Paul "the Deacon"—the author of a fairly classical sapphic ode on St John the Baptist—in Italy, were successful followers of the Ambrosian and Gregorian styles. Eleven metrical hymns are attributed to Bede by Cassander; and there are also in one of Bede's works (*Collectanea et flores*) two rhythmical hymns of considerable length on the Day of Judgment, with the refrains "In tremendo die" and "Attende homo," both irregularly rhymed, and, in parts, not unworthy of comparison with the "Dies Irae." Paulinus, patriarch of Aquileia, contemporary with Paul, wrote rhythmical trimeter iambics in a manner peculiar to himself. Theodulph, bishop of Orleans (793–835), author of the famous processional hymn for Palm Sunday in hexameters and pentameters, "Gloria, laus, et honor tibi sit, Rex Christe Redemptor" ("Glory and honour and laud be to Thee, King Christ the Redeemer"), and Hrabanus Maurus, archbishop of Mainz, the pupil of Alcuin, and the most learned theologian of his day, enriched the church with some excellent works. Among the anonymous hymns of the same period there are three of great beauty, of which the influence may be traced in most, if not all, of the "New Jerusalem" hymns of later generations, including those of Germany and Great Britain:—"Urbs beata Hierusalem" ("Blessed city, heavenly Salem"); "Alleluia piis edite laudibus" ("Alleluias sound ye in strains of holy praise"—called, from its burden, "Alleluia perenne"); and "Alleluia dulce carmen" ("Alleluia, song of sweetness"), which, being found in Anglo-Saxon hymnaries certainly older than the Conquest, cannot be of the late date assigned to it, in his *Mediaeval Hymns and Sequences*, by Neale. These were followed by the "Chorus novae Hierusalem" ("Ye Choirs of New Jerusalem") of Fulbert, bishop of Chartres. This group of hymns is remarkable for an attractive union of melody, imagination, poetical colouring and faith. It represents, perhaps, the best and highest type of the middle school, between the severe Ambrosian simplicity and the florid luxuriance of later times.

Veni Creator. Another celebrated hymn, which belongs to the first medieval period, is the "Veni Creator Spiritus" ("Come, Holy Ghost, our souls inspire"). The earliest recorded occasion of its use is that of a translation (898) of the relics of St Marcellus, mentioned in the *Annals* of the Benedictine order. It has since been constantly sung throughout Western Christendom (as versions of it still are in the Church of England), as part of the appointed offices for the coronation of kings, the consecration and ordination of bishops and priests, the assembling of synods and other great ecclesiastical solemnities. It has been attributed—probably in consequence of certain corruptions in the text of Ekkehard's *Life of Notker* (a work of the 13th century)—to Charlemagne. Ekkehard wrote in the Benedictine monastery of St Gall, to which Notker belonged, with full access to its records; and an ignorant interpolator, regardless of chronology, added, at some later date, the word "Great" to the name of "the emperor Charles," wherever it was mentioned in that work. The biographer relates that Notker—a man of a gentle, contemplative nature, observant of all around him, and accustomed to find spiritual and poetical suggestions in common

Notker.

sights and sounds—was moved by the sound of a mill-wheel to compose his "sequence" on the Holy Spirit, "Sancti Spiritus adsit nobis gratia" ("Present with us ever be the Holy Spirit's grace"); and that, when finished, he sent it as a present to "the emperor Charles," who in return sent him back, "by the same messenger," the hymn "Veni Creator," which (says Ekkehard) the same "Spirit had inspired him to write" ("Sibi idem Spiritus inspiraverat"). If this story is to be credited—and, from its circumstantial and almost dramatic character, it has an air of truth—the author of "Veni Creator" was not Charlemagne, but his grandson the emperor Charles the Bald. Notker himself long survived that emperor, and died in 912.

The invention of "sequences" by Notker may be regarded as the beginning of the later medieval epoch of Latin hymnody.

Sequences. In the eucharistic service, in which (as has been stated) hymns were not generally used, it had been the practice, except at certain seasons, to sing "laud," or "Alleluia," between the epistle and the gospel, and to fill up what would otherwise have been a long pause, by extending the cadence upon the two final vowels of the "Alleluia" into a protracted strain of music. It occurred to Notker that, while preserving the spirit of that part of the service, the monotony of the interval might be relieved by introducing at that point a chant of praise specially composed for the purpose. With that view he produced the peculiar species of rhythmical composition which obtained the name of "sequentia" (probably from following after the close of the "Alleluia"), and also that of "prosa," because its structure was originally irregular and unmetrical, resembling in this respect the Greek "troparia," and the "Te Deum," "Benedicite" and canticles. That it was in some measure suggested by the forms of the later Greek hymnody seems probable, both from the intercourse (at that time frequent) between the Eastern and Western churches, and from the application by Ekkehard, in his biography and elsewhere (*e.g.* in Lyndwood's *Provinciale*), of some technical terms, borrowed from the Greek terminology, to works of Notker and his school and to books containing them.

Dr Neale, in a learned dissertation prefixed to his collection of sequences from medieval Missals, and enlarged in a Latin letter to H. A. Daniel (printed in the fifth volume of Daniel's *Thesaurus hymnologicus*), investigated the laws of caesura and modulation which are discoverable in these works. Those first brought into use were sent by their author to Pope Nicholas I., who authorized their use, and that of others composed after the same model by other brethren of St Gall, in all churches of the West.

Although the sequences of Notker and his school, which then rapidly passed into most German, French and British Missals, were not metrical, the art of "assonance" was much practised in them. Many of those in the Sarum and French Missals have every verse, and even every clause or division of a verse, ending with the same vowel "a"—perhaps with some reference to the terminal letter of "Alleluia." Artifices such as these naturally led the way to the adaptation of the same kind of composition to regular metre and fully developed rhyme. Neale's full and large collection, and the second volume of Daniel's *Thesaurus*, contain numerous examples, both of the "proses," properly so called, of the Notkerian type, and of those of the later school, which (from the religious house to which its chief writer belonged) has been called "Victorine." Most Missals appear to have contained some of both kinds. In the majority of those from which Neale's specimens are taken, the metrical kind largely prevailed; but in some (*e.g.* those of Sarum and Liége) the greater number were Notkerian.

Of the sequence on the Holy Ghost, sent by Notker (according to Ekkehard) to Charles the Bald, Neale says that it "was in use all over Europe, even in those countries, like Italy and Spain, which usually rejected sequences"; and that, "in the Missal of Palencia, the priest was ordered to hold a white dove in his hands, while intoning the first syllables, and then to let it go." Another of the most remarkable of Notker's sequences, beginning "Media in vita" ("In the midst of life we are in death"), is said to have been suggested to him while observing some workmen engaged in the construction of a bridge over a torrent near his monastery. Catherine Winkworth (*Christian Singers of Germany*, 1869) states that this was long used as a battle-song, until the custom was forbidden, on account of its being supposed to exercise a magical influence. A translation of it ("Mitten wir im Leben sind") is one of Luther's funeral hymns; and all but the opening sentence of that part of the burial service of the Church of England which is directed to be "said or sung" at the grave, "while the corpse is made ready to be laid into the earth," is taken from it.

The "Golden Sequence," "Veni, sancte Spiritus" ("Holy Spirit, Lord of Light"), is an early example of the transition of sequences from a simply rhythmical to a metrical form. Archbishop Trench, who esteemed it "the loveliest of all the hymns in the whole circle of Latin sacred poetry," inclined to give credit to a tradition which ascribes its authorship to Robert II., king of France, son of Hugh Capet. Others have assigned to it a later date—some attributing it to Pope Innocent III., and some to Stephen Langton, archbishop of Canterbury. Many translations, in German, English and other languages, attest its merit. Berengarius of Tours, St Bernard of Clairvaux and Abelard, in the 11th century and early in the 12th, followed in the same track; and the art of the Victorine school was carried to its greatest perfection by Adam of St Victor (who died between 1173 and 1194)—"the most fertile, and" (in the concurrent judgment of Archbishop Trench and Neale) "the greatest of the Latin hymnographers of the Middle Ages." The archbishop's selection contains many excellent specimens of his works.

Dies Irae. But the two most widely celebrated of all this class of compositions—works which have exercised the talents of the greatest musical composers, and of innumerable translators in almost all languages—are the "Dies Irae" ("That day of wrath, that dreadful day"), by Thomas of Celano, the companion and biographer of St Francis of Assisi, and the "Stabat Mater dolorosa" ("By the cross sad vigil keeping") of Jacopone, or Jacobus de Benedictis, a Franciscan humorist and reformer, who was persecuted by Pope Boniface VIII. for his satires on the prelacy of the time, and died in 1306. ***Stabat Mater.*** Besides these, the 13th century produced the famous sequence "Lauda Sion salvatorem" ("Sion, lift thy voice and sing"), and the four other well-known sacramental hymns of St Thomas Aquinas, viz. "Pange lingua gloriosi corporis mysterium" ("Sing, my tongue, the Saviour's glory"), "Verbum supernum prodiens" ("The Word, descending from above"—not to be confounded with the Ambrosian hymn from which it borrowed the first line), ***Aquinas.*** "Sacris solemniis juncta sint gaudia" ("Let us with hearts renewed our grateful homage pay"), and "Adoro Te devote, latens Deitas" ("O Godhead hid, devoutly I adore Thee")—a group of remarkable compositions, written by him for the then new festival of Corpus Christi, of which he induced Pope Urban IV. (1261–1265) to decree the observance. In these (of which all but "Adoro Te devote" passed rapidly into breviaries and missals) the doctrine of transubstantiation is set forth with a wonderful degree of scholastic precision; and they exercised, probably, a not unimportant influence upon the general reception of that dogma. They are undoubtedly works of genius, powerful in thought, feeling and expression.

Medieval hymns. These and other medieval hymn-writers of the 12th and 13th centuries may be described, generally, as poet-schoolmen. Their tone is contemplative, didactic, theological; they are especially fertile and ingenious in the field of mystical interpretation. Two great monasteries in the East had, in the 8th and 9th centuries, been the principal centres of Greek hymnology; and, in the West, three monasteries—St Gall, near Constance (which was long the especial seat of German religious literature), Cluny in Burgundy and St Victor, near Paris—obtained a similar distinction. St Gall produced, besides Notker, several distinguished sequence writers, probably his pupils—Hartmann, Hermann and Gottschalk—to the last of whom Neale ascribes the "Alleluiatic Sequence" ("Cantemus cuncti melodum nunc Alleluia"), well known in England through his translation, "The strain upraise of joy and praise." The chief poets of Cluny were two of its abbots, Odo and Peter the Venerable (1122–1156), and one of Peter's monks, Bernard of Morlaix, who wrote the remarkable poem on "Contempt of the World" in about 3000 long rolling "leonine-dactylic" verses, from parts of which Neale's popular hymns, "Jerusalem the golden," &c., are taken. The abbey of St Victor, besides Adam and his follower Pistor, was destined afterwards to produce the most popular church poet of the 17th century.

Bernard of Clairvaux.

There were other distinguished Latin hymn-writers of the later medieval period besides those already mentioned. The name of St Bernard of Clairvaux cannot be passed over with the mere mention of the fact that he was the author of some metrical sequences. He was, in truth, the father, in Latin hymnody, of that warm and passionate form of devotion which some may consider to apply too freely to Divine Objects the language of human affection, but which has, nevertheless, been popular with many devout persons, in Protestant as well as Roman Catholic churches. F. von Spee, "Angelus Silesius," Madame Guyon, Bishop Ken, Count Zinzendorf and Frederick William Faber may be regarded as disciples in this school. Many hymns, in various languages, have been founded upon St Bernard's "Jesu dulcis memoria" ("Jesu, the very thought of Thee"), "Jesu dulcedo cordium" ("Jesu, Thou joy of loving hearts") and "Jesu Rex admirabilis" ("O Jesu, King most wonderful")—three portions of one poem, nearly 200 lines long. Pietro Damiani, the friend of Pope Gregory VII., Marbode, bishop of Rennes, in the 11th, Hildebert, archbishop of Tours, in the 12th, and St Bonaventura in the 13th centuries, are other eminent men who added poetical fame as hymnographers to high public distinction.

Before the time of the Reformation, the multiplication of sequences (often as unedifying in matter as unpoetical in style) had done much to degrade the common conception of hymnody. In some parts of France, Portugal, Sardinia and Bohemia, their use in the vernacular language had been allowed. In Germany also there were vernacular sequences as early as the 12th century, specimens of which may be seen in the third chapter of C. Winkworth's *Christian Singers of Germany*. Scoffing parodies upon sequences are said to have been among the means used in Scotland to discredit the old church services. After the 15th century they were discouraged at Rome. They retained for a time some of their old popularity among German Protestants, and were only gradually relinquished in France. A new "prose," in honour of St Maxentia, is among the compositions of Jean Baptiste Santeul; and Dr Daniel's second volume closes with one written in 1855 upon the dogma of the Immaculate Conception.

Roman revision of hymns.

The taste of the Renaissance was offended by all deviations from classical prosody and Latinity. Pope Leo X. directed the whole body of the hymns in use at Rome to be reformed; and the *Hymni novi ecclesiastici juxta veram metri et Latinitatis normam*, prepared by Zacharie Ferreri (1479–1530), a Benedictine of Monte Cassino, afterwards a Carthusian and bishop of Guardia, to whom Leo had committed that task, appeared at Rome in 1525, with the sanction of a later pope, Clement VII. The next step was to revise the whole Roman Breviary. That undertaking, after passing through several stages under different popes (particularly Pius V. and Clement VIII.), was at last brought to a conclusion by Urban VIII., in 1631. From this revised Breviary a large number of medieval hymns, both of the earlier and the later periods, were excluded; and in their places many new hymns, including some by Pope Urban himself, and some by Cardinal Bellarmine and another cardinal (Silvius Antonianus) were introduced. The hymns of the primitive epoch, from Hilary to Gregory the Great, for the most part retained their places (especially in the offices for every day of the week); and there remained altogether from seventy to eighty of earlier date than the 11th century. Those, however, which were so retained were freely altered, and by no means generally improved. The revisers appointed by Pope Urban (three learned Jesuits—Strada, Gallucci and Petrucci) professed to have made "as few changes as possible" in the works of Ambrose, Gregory, Prudentius, Sedulius, Fortunatus and other "poets of great name." But some changes, even in those works, were made with considerable boldness; and the pope, in the "constitution" by which his new book was promulgated, boasted that, "with the exception of a very small number ('perpaucis'), which were either prose or merely rhythmical, all the hymns had been made conformable to the laws of prosody and Latinity, those which could not be corrected by any milder method being entirely rewritten." The latter fate befel, among others, the beautiful "Urbs beata Hierusalem," which now assumed the form (to many, perhaps, better known), of "Caelestis urbs Jerusalem." Of the "very few" which were spared, the chief were "Ave maris stella" ("Gentle star of ocean"), "Dies Irae," "Stabat Mater dolorosa," the hymns of Thomas Aquinas, two of St Bernard and one Ambrosian hymn, "Jesu nostra Redemptio" ("O Jesu, our Redemption"), which approaches nearer than others to the tone of St Bernard. A then recent hymn of St Francis Xavier, with scarcely enough merit of any kind to atone for its neglect of prosody, "O Deus, ego amo Te" ("O God, I love Thee, not because"), was at the same time introduced without change. This hymnary of Pope Urban VIII. is now in general use throughout the Roman Communion.

Parisian revisions.

The Parisian hymnary underwent three revisions—the first in 1527, when a new "Psaltery with hymns" was issued. In this such changes only were made as the revisers thought justifiable upon the principle of correcting supposed corruptions of the original text. Of these, the transposition, "Urbs Jerusalem beata," instead of "Urbs beata Hierusalem," may be taken as a typical example. The next revision was in 1670–1680, under Cardinal Péréfixe, preceptor of Louis XIV., and Francis Harlay, successively archbishops of Paris, who employed for this purpose Claude Santeul, of the monastery of St Magloire, and, through him, obtained the assistance of other French scholars, including his more celebrated brother, Jean Baptiste Santeul, of the abbey of St Victor—better known as "Santolius Victorinus." The third and final revision was completed in 1735, under the primacy of Cardinal Archbishop de Vintimille, who engaged for it the services of Charles Coffin, then rector of the university of Paris. Many old hymns were omitted in Archbishop Harlay's Breviary, and a large number of new compositions, by the Santeuls and others, was introduced. It still, however, retained in their old places (without further changes than had been made in 1527) about seventy of earlier date than the 11th century—including thirty-one Ambrosian, one by Hilary, eight by Prudentius, seven by Fortunatus, three by Paul the Deacon, two each by Sedulius, Elpis, Gregory and Hrabanus Maurus, "Veni Creator" and "Urbs Jerusalem beata." Most of these disappeared in 1735, although Cardinal Vintimille, in his preface, professed to have still admitted the old hymns, except when the new were better—("veteribus hymnis locus datus est, nisi quibus, ob sententiarum vim, elegantiam verborum, et teneriores pietatis sensus, recentiores anteponi satius visum est"). The number of the new was, at the same time, very largely increased. Only twenty-one more ancient than the 16th century remained, of which those belonging to the primitive epoch were but eight, viz. four Ambrosian, two by Fortunatus and one each by Prudentius and Gregory. The number of Jean Baptiste Santeul's hymns rose to eighty-nine; those by Coffin—including some old hymns, *e.g.* "Jam lucis orto sidere" ("Once more the sun is beaming bright"), which he substantially re-wrote—were eighty-three; those of other modern French writers, ninety-seven. Whatever opinion may be entertained of the principles on which these Roman and Parisian revisions proceeded, it would be unjust to deny very high praise as hymn-writers to several of their poets, especially to Coffin and Jean Baptiste Santeul. The noble hymn by Coffin, beginning—

"O luce qui mortalibus	"O Thou who in the light dost dwell,
Lates inaccessa, Deus,	To mortals unapproachable,
Praesente quo sancti tremunt	Where angels veil them from Thy rays,
Nubuntque vultus angeli,"	And tremble as they gaze,"

and several others of his works, breathe the true Ambrosian spirit; and though Santeul (generally esteemed the better poet of the two) delighted in alcaics, and did not greatly affect the primitive manner, there can be no question as to the excellence of such hymns as his "Fumant Sabaeis templa vaporibus" ("Sweet incense breathes around"), "Stupete gentes, fit Deus hostia" ("Tremble, ye Gentile lands"), "Hymnis dum resonat curia caelitum" ("Ye in the house of heavenly morn"), and "Templi sacratas pande, Sion, fores" ("O Sion, open wide thy gates"). It is a striking testimony to the merits of those writers that such accomplished translators as the Rev. Isaac Williams and the Rev. John Chandler appear (from the title-page of the latter, and the prefaces of both) to have supposed their hymns to be "ancient" and "primitive." Among the other authors associated with them, perhaps the first place is due to the Abbé Besnault, of Sens, who contributed to the book of 1735 the "Urbs beata vera pacis Visio Jerusalem," in the opinion of Neale "much superior" to the "Caelestis urbs Jerusalem" of the Roman Breviary. This stood side by side with the "Urbs Jerusalem beata" of 1527 (in the office for the dedication of churches) till 1822, when the older form was at last finally excluded by Archbishop de Quelen.

The Parisian Breviary of 1735 remained in use till the national French service-books were superseded (as they have lately been, generally, if not universally) by the Roman. Almost all French dioceses followed, not indeed the Breviary, but the example, of Paris; and before the end of the 18th century the ancient Latin hymnody was all but banished from France.

Modern Latin hymns.

In some parts of Germany, after the Reformation, Latin hymns continued to be used even by Protestants. This was the case at Halberstadt until quite a recent date. In England, a few are still occasionally used in the older universities and colleges. Some, also, have been composed in both countries since the Reformation. The "Carmina lyrica" of Johann Jakob Balde, a native of Alsace, and a Jesuit priest in Bavaria, have received high commendation from very eminent German critics, particularly Herder and Augustus Schlegel. Some of the Latin hymns of William Alard (1572–1645), a Protestant refugee from

Belgium, and pastor in Holstein, have been thought worthy of a place in Archbishop Trench's selection. Two by W. Petersen (printed at the end of Haberkorn's supplement to Jacobi's *Psalmodia Germanica*) are good in different ways—one, " Jesu dulcis amor meus " (" Jesus, Thee my soul doth love "), being a gentle melody of spiritual devotion, and the other, entitled *Spes Sionis*, violently controversial against Rome. An English hymn of the 17th century, in the Ambrosian style, " Te Deum Patrem colimus " (" Almighty Father, just and good "), is sung on every May-Day morning by the choristers of Magdalen College, Oxford, from the top of the tower of their chapel; and another in the style of the Renaissance, of about the same date, " Te de profundis, summe Rex " (" Thee from the depths, Almighty King), long formed part of a grace formerly sung by the scholars of Winchester College.

5. *German Hymnody.*—Luther was a proficient in and a lover of music. He desired (as he says in the preface to his hymn-book of 1545) that this " beautiful ornament " might " in a right manner serve the great Creator and His Christian people." The persecuted Bohemian or Hussite Church, then settled on the borders of Moravia under the name of " United Brethren," had sent to him, on a mission in 1522, Michael Weiss, who not long afterwards published a number of German translations from old Bohemian hymns (known as those of the " Bohemian Brethren "), with some of his own. These Luther highly approved and recommended. He himself, in 1522, published a small volume of eight hymns, which was enlarged to 63 in 1527, and to 125 in 1545. He had formed what he called a " house choir " of musical friends, to select such old and popular tunes (whether secular or ecclesiastical) as might be found suitable, and to compose new melodies, for church use. His fellow labourers in this field (besides Weiss) were Justus Jonas, his own especial colleague; Paul Eber, the disciple and friend of Melanchthon; John Walther, choirmaster successively to several German princes, and professor of arts, &c., at Wittenberg; Nicholas Decius, who from a monk became a Protestant teacher in Brunswick, and translated the " Gloria in Excelsis," &c.; and Paul Speratus, chaplain to Duke Albert of Prussia in 1525. Some of their works are still popular in Germany. Weiss's " Funeral Hymn," " Nun lasst uns den Leib begraben " (" Now lay we calmly in the grave "); Eber's " Herr Jesu Christ, wahr Mensch und Gott " (" Lord Jesus Christ, true Man and God "), and " Wenn wir in höchsten Nöthen sein " (" When in the hour of utmost need "); Walther's " New Heavens and new Earth " (" Now fain my joyous heart would sing "); Decius's " To God on high be thanks and praise "; and Speratus's " Salvation now has come for all," are among those which at the time produced the greatest effect, and are still best remembered.

Luther.

Luther's own hymns, thirty-seven in number (of which about twelve are translations or adaptations from Latin originals), are for the principal Christian seasons; on the sacraments, the church, grace, death, &c.; and paraphrases of seven psalms, of a passage in Isaiah, and of the Lord's Prayer, Ten Commandments, Creed, Litany and " Te Deum." There is also a very touching and stirring song on the martyrdom of two youths by fire at Brussels, in 1523–1524. Homely and sometimes rugged in form, and for the most part objective in tone, they are full of fire, manly simplicity and strong faith. Three rise above the rest. One for Christmas, " Vom Himmel hoch da komm ich her " (" From Heaven above to earth I come "), has a reverent tenderness, the influence of which may be traced in many later productions on the same subject. That on salvation through Christ, of a didactic character, " Nun freuet euch, lieben Christen g'mein " (" Dear Christian people, now rejoice "), is said to have made many conversions, and to have been once taken up by a large congregation to silence a Roman Catholic preacher in the cathedral of Frankfort. Pre-eminent above all is the celebrated paraphrase of the 46th Psalm: " Ein' feste Burg ist unser Gott " (" A sure stronghold our God is He ")—" the production " (as Ranke says) " of the moment in which Luther, engaged in a conflict with a world of foes, sought strength in the consciousness that he was defending a divine cause which could never perish." Carlyle compares it to " a sound of Alpine avalanches, or the first murmur of earthquakes." Heine called it " the Marseillaise of the Reformation."

Luther spent several years in teaching his people at Wittenberg to sing these hymns, which soon spread over Germany. Without adopting the hyperbolical saying of Coleridge, that " Luther did as much for the Reformation by his hymns as by his translation of the Bible," it may truly be affirmed that, among the secondary means by which the success of the Reformation was promoted, none was more powerful. They were sung everywhere—in the streets and fields as well as the churches, in the workshop and the palace, " by children in the cottage and by martyrs on the scaffold." It was by them that a congregational character was given to the new Protestant worship. This success they owed partly to their metrical structure, which, though sometimes complex, was recommended to the people by its ease and variety; and partly to the tunes and melodies (many of them already well known and popular) to which they were set. They were used as direct instruments of teaching, and were therefore, in a large measure, didactic and theological; and it may be partly owing to this cause that German hymnody came to deviate, so soon and so generally as it did, from the simple idea expressed in the ancient Augustinian definition, and to comprehend large classes of compositions which, in most other countries, would be thought hardly suitable for church use.

Followers of Luther.

The principal hymn-writers of the Lutheran school, in the latter part of the 16th century, were Nikolaus Selnecker, Herman and Hans Sachs, the shoemaker of Nuremberg, also known in other branches of literature. All these wrote some good hymns. They were succeeded by men of another sort, to whom F. A. Cunz gives the name of " master-singers," as having raised both the poetical and the musical standard of German hymnody:—Bartholomäus Ringwaldt, Ludwig Helmbold, Johannes Pappus, Martin Schalling, Rutilius and Sigismund Weingartner. The principal topics of their hymns (as if with some foretaste of the calamities which were soon to follow) were the vanity of earthly things, resignation to the Divine will, and preparation for death and judgment. The well-known English hymn, " Great God, what do I see and hear," is founded upon one by Ringwaldt. Of a quite different character were two of great beauty and universal popularity, composed by Philip Nicolai, a Westphalian pastor, during a pestilence in 1597, and published by him, with fine chorales, two years afterwards. One of these (the " Sleepers wake! a voice is calling," of Mendelssohn's oratorio, *St Paul*) belongs to the family of Advent or New Jerusalem hymns. The other, a " Song of the believing soul concerning the Heavenly Bridegroom " (" Wie schön leucht't uns der Morgenstern "—" O morning Star, how fair and bright "), became the favourite marriage hymn of Germany.

Period of Thirty Years' War.

The hymns produced during the Thirty Years' War are characteristic of that unhappy time, which (as Miss Winkworth says) " caused religious men to look away from this world," and made their songs more and more expressive of personal feelings. In point of refinement and graces of style, the hymn-writers of this period excelled their predecessors. Their taste was chiefly formed by the influence of Martin Opitz, the founder of what has been called the " first Silesian school " of German poetry, who died comparatively young in 1639, and who, though not of any great original genius, exercised much power as a critic. Some of the best of these works were by men who wrote little. In the famous battle-song of Gustavus Adolphus, published (1631) after the victory of Breitenfeld, for the use of his army, " Verzage nicht du Häuflein klein " (" Fear not, O little flock, the foe "), we have almost certainly a composition of the hero-king himself, the versification corrected by his chaplain Jakob Fabricius (1593–1654) and the music composed by Michael Altenburg, whose name has been given to the hymn. This, with Luther's paraphrase of the 67th Psalm, was sung by Gustavus and his soldiers before the battle of Lützen in 1632. Two very fine hymns, one of prayer for deliverance and peace, the other of trust in God under calamities, were written about the same time by Matthäus Löwenstern, a saddler's son, poet, musician and statesman, who was ennobled after the peace by the emperor

Ferdinand III. Martin Rinckhart, in 1636, wrote the "Chorus of God's faithful children" ("Nun danket alle Gott"—"Now thank we all our God"), introduced by Mendelssohn in his "Lobgesang," which has been called the "Te Deum" of Germany, being usually sung on occasions of public thanksgiving. Weissel, in 1635, composed a beautiful Advent hymn ("Lift up your heads, ye mighty gates"), and J. M. Meyfart, professor of theology at Erfurt, in 1642, a fine adaptation of the ancient "Urbs beata Hierusalem." The hymn of trust in Providence by George Neumark, librarian to that duke of Weimar ("Wer nur den lieben Gott lässt walten"—"Leave God to order all thy ways"), is scarcely, if at all, inferior to that of Paul Gerhardt on the same theme. Paul Flemming, a great traveller and lover of nature, who died in 1639, also wrote excellent compositions, coloured by the same tone of feeling; and some, of great merit, were composed, soon after the close of the war, by Louisa Henrietta, electress of Brandenburg, granddaughter of the famous admiral Coligny, and mother of the first king of Prussia. With these may be classed (though of later date) a few striking hymns of faith and prayer under mental anxiety, by Anton Ulrich, duke of Brunswick.

The most copious, and in their day most esteemed, hymn-writers of the first half of the 17th century, were Johann Heermann and Johann Rist. Heermann, a pastor in Silesia, the theatre (in a peculiar degree) of war and persecution, experienced in his own person a very large share of the miseries of the time, and several times narrowly escaped a violent death. His *Devoti musica cordis*, published in 1630, reflects the feelings natural under such circumstances. With a correct style and good versification, his tone is subjective, and the burden of his hymns is not praise, but prayer. Among his works (which enter largely into most German hymn-books), two of the best are the "Song of Tears" and the "Song of Comfort," translated by Miss Winkworth in her *Christian Singers of Germany*. Rist published about 600 hymns, "pressed out of him," as he said, "by the cross." He was a pastor, and son of a pastor, in Holstein, and lived after the peace to enjoy many years of prosperity, being appointed poet-laureate to the emperor and finally ennobled. The bulk of his hymns, like those of other copious writers, are of inferior quality; but some, particularly those for Advent, Epiphany, Easter Eve and on Angels, are very good. They are more objective than those of Heermann, and written, upon the whole, in a more manly spirit.

Rist.

Dach.

Next to Heermann and Rist in fertility of production, and above them in poetical genius, was Simon Dach, professor of poetry at Königsberg, who died in 1659. Miss Winkworth ranks him high among German poets, "for the sweetness of form and depth of tender contemplative emotion to be found in his verses."

Gerhardt.

The fame of all these writers was eclipsed in the latter part of the same century by three of the greatest hymnographers whom Germany has produced—Paul Gerhardt (1604–1676), Johann Franck (1618–1677) and Johann Scheffler (1624–1677), the founder of the "second Silesian school," who assumed the name of "Angelus Silesius." Gerhardt is by universal consent the prince of Lutheran poets. His compositions, which may be compared, in many respects, to those of the *Christian Year*, are lyric poems, of considerable length, rather than hymns, though many hymns have been taken from them. They are, with few exceptions, subjective, and speak the language of individual experience. They occupy a middle ground between the masculine simplicity of the old Lutheran style and the highly wrought religious emotion of the later pietists, towards whom they on the whole incline. Being nearly all excellent, it is not easy to distinguish among the 123 those which are entitled to the highest praise. Two, which were written one during the war and the other after the conclusion of peace, "Zeuch ein zu deinen Thoren" ("Come to Thy temple here on earth"), and "Gottlob, nun ist erschollen" ("Thank God, it hath resounded"), are historically interesting. Of the rest, one is well known and highly appreciated in English through Wesley's translation, "Commit thou all thy ways"; and the evening and spring-tide hymns ("Now all the woods are sleeping" and "Go forth, my heart, and seek delight") show an exquisite feeling for nature; while nothing can be more tender and pathetic than "Du bist zwar mein und bleibest mein" ("Thou'rt mine, yes, still thou art mine own"), on the death of his son.

Franck.

Franck, who was burgomaster of Guben in Lusatia, has been considered by some second only to Gerhardt. If so, it is with a great distance between them. His approach to the later pietists is closer than that of Gerhardt. His hymns were published, under the title of *Geistliche und weltliche Gedichte*, in 1674, some of them being founded on Ambrosian and other Latin originals. Miss Winkworth gives them the praise of a condensed and polished style and fervid and impassioned thought.

Scheffler.

It was after his conversion to Roman Catholicism that Scheffler adopted the name of "Angelus Silesius," and published in 1657 his hymns, under a fantastic title, and with a still more fantastic preface. Their keynote is divine love; they are enthusiastic, intense, exuberant in their sweetness, like those of St Bernard among medieval poets. An adaptation of one of them, by Wesley, "Thee will I love, my Strength, my Tower," is familiar to English readers. Those for the first Sunday after Epiphany, for Sexagesima Sunday and for Trinity Sunday, in *Lyra Germanica*, are good examples of his excellences, with few of his defects. His hymns are generally so free from the expression, or even the indirect suggestion, of Roman Catholic doctrine, that it has been supposed they were written before his conversion, though published afterwards. The evangelical churches of Germany found no difficulty in admitting them to that prominent place in their services which they have ever since retained.

Pietists.

Towards the end of the 17th century, a new religious school arose, to which the name of "Pietists" was given, and of which Philipp Jakob Spener was esteemed the founder. He and his pupils and successors, August Hermann Francke and Anastasius Freylinghausen, all wrote hymns. Spener's hymns are not remarkable, and Francke's are not numerous. Freylinghausen was their chief singer; his rhythm is lively, his music florid; but, though his book attained extraordinary popularity, he was surpassed in solid merit by other less fertile writers of the same school. The "Auf hinauf zu deiner Freude" ("Up, yes, upward to thy gladness") of Schade may recall to an English reader a hymn by Seagrave, and more than one by Lyte; the "Malabarian hymn" (as it was called by Jacobi) of Johann Schütz, "All glory to the Sovereign Good," has been popular in England as well as Germany; and one of the most exquisite strains of pious resignation ever written is "Whate'er my God ordains is right," by Samuel Rodigast.

Neander.

Joachim Neander, a schoolmaster at Düsseldorf, and a friend of Spener and Schütz (who died before the full development of the "Pietistic" school), was the first man of eminence in the "Reformed" or Calvinistic Church who imitated Lutheran hymnody. This he did, while suffering persecution from the elders of his own church for some other religious practices, which he had also learnt from Spener's example. As a poet, he is sometimes deficient in art; but there is feeling, warmth and sweetness in many of his "Bundeslieder" or "Songs of the Covenant," and they obtained general favour, both in the Reformed and in Lutheran congregations. The Summer Hymn ("O Thou true God alone") and that on the glory of God in creation ("Lo, heaven and earth and sea and air") are instances of his best style.

Schmolke.

With the "Pietists" may be classed Benjamin Schmolke and Dessler, representatives of the "Orthodox" division of Spener's school; Philipp Friedrich Hiller, their leading poet in South Germany; Gottfried Arnold and Gerhard Tersteegen, who were practically independent of ecclesiastical organization, though connected, one with the "Orthodox" and the other with the "Reformed" churches; and Nikolaus Ludwig, Graf von Zinzendorf. Schmolke, a pastor in Silesia, called the Silesian Rist (1672–1737), was perhaps the most voluminous of all German hymn-writers. He wrote 1188 religious poems and hymns, a large proportion of which do not rise above mediocrity. His style, if less refined, is also less subjective and more simple than that of most of his contemporaries. Among his best and most attractive works, which indeed, it would be difficult to praise too highly, are the "Hosianna David's Sohn," for Palm Sunday—much resembling a shorter hymn by Jeremy Taylor; and the Ascension, Whitsuntide and Sabbath hymns—"Heavenward doth our journey tend," "Come deck our feast to-day," and "Light of light, enlighten me."

Dessler. Dessler was a greater poet than Schmolke. Few hymns, of the subjective kind, are better than his "I will not let Thee go, Thou Help in time of need," "O Friend of souls, how well is me," and "Now, the pearly gates unfold."

Hiller. Hiller (1699–1769), was a pastor in Württemberg who, falling into ill-health during the latter part of his ministry, published a *Geistliche Liederhöstlein* in a didactic vein, with more taste than power, but (as Miss Winkworth says) in a tone of "deep, thoughtful, practical piety." They were so well adapted to the wants of his people that to this day Hiller's *Casket* is prized, next to their Bibles, by the peasantry of Württemberg; and the numerous emigrants from that part of Germany to America and other foreign countries generally take it with them wherever they go.

Arnold. Arnold, a professor at Giessen, and afterwards a pastor in Brandenburg, was a man of strong will, uncompromising character and austere views of life, intolerant and controversial towards those whose doctrine or practice he disapproved, and more indifferent to separatism and sectarianism than the "orthodox" generally thought right. His hymns, like those of Augustus M. Toplady, whom in these respects he resembled, unite with considerable strength more gentleness and breadth of sympathy than might be expected from a man of such a character.

Tersteegen. Tersteegen (1697–1769), who never formally separated himself from the "Reformed" communion, in which he was brought up, but whose sympathies were with the Moravians and with Zinzendorf, was, of all the more copious German hymn-writers after Luther, perhaps the most remarkable man. Pietist, mystic and missionary, he was also a great religious poet. His 111 hymns were published in 1731, in a volume called *Geistlicher Blumengärtlein inniger Seelen*. They are intensely individual, meditative and subjective. Wesley's adaptations of two—"Lo! God is here; let us adore," and "Thou hidden Love of God, whose source"—are well known. Among those translated by Miss Winkworth, "O God, O Spirit, Light of all that live," and "Come, brethren, let us go," are specimens which exhibit favourably his manner and power. Miss Cox speaks of him as "a gentle heaven-inspired soul, whose hymns are the reflection of a heavenly, happy life, his mind being full of a child-like simplicity"; and his own poem on the child-character, which Miss Winkworth has appropriately connected with Innocents' day ("Dear Soul, couldst thou become a child")—one of his best compositions, exquisitely conceived and expressed—shows that this was in truth the ideal which he sought to realize.

Zinzendorf. The hymns of Zinzendorf are often disfigured by excess in the application of the language and imagery of human affections to divine objects; and this blemish is also found in many later Moravian hymns. But one hymn, at least, of Zinzendorf may be mentioned with unqualified praise, as uniting the merits of force, simplicity and brevity—"Jesu, geh voran" ("Jesus, lead the way"), which is taught to most children of religious parents in Germany. Wesley's "Jesus, Thy blood and righteousness" is a translation from Zinzendorf.

Gellert. The transition from Tersteegen and Zinzendorf to Gellert and Klopstock marks strongly the reaction against Pietism which took place towards the middle of the 18th century. The *Geistlichen Oden und Lieder* of Christian F. Gellert were published in 1757, and are said to have been received with an enthusiasm almost like that which "greeted Luther's hymns on their first appearance." It is a proof of the moderation both of the author and of his times that they were largely used, not only by Protestant congregations, but in those German Roman Catholic churches in which vernacular services had been established through the influence of the emperor Joseph II. They became the model which was followed by most succeeding hymn-writers, and exceeded all others in popularity till the close of the century, when a new wave of thought was generated by the movement which produced the French Revolution. Since that time they have been, perhaps, too much depreciated. They are, indeed, cold and didactic, as compared with Scheffler or Tersteegen; but there is nevertheless in them a spirit of genuine practical piety; and, if not marked by genius, they are pure in taste, and often terse, vigorous and graceful.

Klopstock. Klopstock, the author of the *Messiah*, cannot be considered great as a hymn-writer, though his "Sabbath Hymn" (of which there is a version in *Hymns from the Land of Luther*) is simple and good. Generally his hymns (ten of which are translated in Sheppard's *Foreign Sacred Lyre*) are artificial and much too elaborate.

Of the "romantic" school, which came in with the French Revolution, the two leading writers are Friedrich Leopold von Hardenberg, called "Novalis," and Friedrich de la Motte Fouqué, the celebrated author of *Undine* and *Sintram*—both romance-writers, as well as poets. The genius of Novalis was early lost to the world; he died in 1801, not thirty years old. Some of his hymns are very beautiful; but even in such works as "Though all to Thee were faithless," and "If only He is mine," there is a feeling of insulation and of despondency as to good in the actual world, which was perhaps inseparable from his ecclesiastical idealism.

Fouqué. Fouqué survived till 1843. In his hymns there is the same deep flow of feeling, richness of imagery and charm of expression which distinguishes his prose works. The two missionary hymns—"Thou, solemn Ocean, rollest to the strand," and "In our sails all soft and sweetly"—and the exquisite composition which finds its motive in the gospel narrative of blind Bartimeus, "Was du vor tausend Jahren" (finely translated both by Miss Winkworth and by Miss Cox), are among the best examples.

Spitta. The later German hymn-writers of the 19th century belong, generally, to the revived "Pietistic" school. Some of the best, Johann Baptist von Albertini, Friedrich Adolf Krummacher, and especially Karl Johann Philipp Spitta (1801–1859) have produced works not unworthy of the fame of their nation. Mr Massie, the able translator of Spitta's *Psalter und Harfe* (Leipzig, 1833), speaks of it as having "obtained for him in Germany a popularity only second to that of Paul Gerhardt." In Spitta's poems (for such they generally are, rather than hymns) the subjective and meditative tone is tempered, not ungracefully, with a didactic element; and they are not disfigured by exaggerated sentiment, or by a too florid and rhetorical style.

6. *British Hymnody.*—After the Reformation, the development of hymnody was retarded, in both parts of Great Britain, by the example and influence of Geneva. Archbishop Cranmer appears at one time to have been disposed to follow Luther's course, and to present to the people, in an English dress, some at least of the hymns of the ancient church. In a letter to King Henry VIII. (October 7, 1544), among some new "processions" which he had himself translated into English, he mentions the Easter hymn, "Salve, festa dies, toto memorabilis aevo" ("Hail, glad day, to be joyfully kept through all generations"), of Fortunatus. In the "Primer" of 1535 (by Marshall) and the one of 1539 (by Bishop Hilsey of Rochester, published by order of the vicar-general Cromwell) there had been several rude English hymns, none of them taken from ancient sources. King Henry's "Primer" of 1545 (commanded by his injunction of the 6th of May 1545 to be used throughout his dominions) was formed on the model of the daily offices of the Breviary; and it contains English metrical translations from some of the best-known Ambrosian and other early hymns. But in the succeeding reign different views prevailed. A new direction had been given to the taste of the "Reformed" congregations in France and Switzerland by the French metrical translation of the Old Testament Psalms, which appeared about 1540. This was the joint work of Clement

Marot, valet or groom of the chamber to Francis I., and Theodore Beza, then a mere youth, fresh from his studies at Orleans.

Marot's psalms were dedicated to the French king and the ladies of France, and, being set to popular airs, became fashionable. They were sung by Francis himself, the queen, the princesses and the courtiers, upon all sorts of secular occasions, and also, more seriously and religiously, by the citizens and the common people. They were soon perceived to be a power on the side of the Reformation. Calvin, who had settled at Geneva in the year of Marot's return to Paris, was then organizing his ecclesiastical system. He rejected the hymnody of the breviaries and missals, and fell back upon the idea, anciently held by Paul of Samosata, and condemned by the fourth council of Toledo, that whatever was sung in churches ought to be taken out of the Scriptures. Marot's Psalter, appearing thus opportunely, was introduced into his new system of worship, and appended to his catechism. On the other hand, it was interdicted by the Roman Catholic priesthood. Thus it became a badge to the one party of the "reformed" profession, and to the other of heresy.

Marot's Psalms.

The example thus set produced in England the translation commonly known as the "Old Version" of the Psalms. It was begun by Thomas Sternhold, whose position in the household of Henry VIII., and afterwards of Edward VI., was similar to that of Marot with Francis I., and whose services to the former of those kings were rewarded by a substantial legacy under his will. Sternhold published versions of nineteen Psalms, with a dedication to King Edward, and died soon afterwards. A second edition appeared in 1551, with eighteen more Psalms added, of Sternhold's translating, and seven others by John Hopkins, a Suffolk clergyman. The work was continued during Queen Mary's reign by British refugees at Geneva, the chief of whom were William Whittingham, afterwards dean of Durham, who succeeded John Knox as minister of the English congregation there, and William Kethe or Keith, said by Strype to have been a Scotsman. They published at Geneva in 1556 a service-book, containing fifty-one English metrical psalms, which number was increased, in later editions, to eighty-seven. On the accession of Queen Elizabeth, this Genevan Psalmody was at once brought into use in England—first (according to a letter of Bishop Jewell to Peter Martyr, dated 5th March 1560) in one London church, from which it quickly spread to others both in London and in other cities. Jewell describes the effect produced by large congregations, of as many as 6000 persons, young and old, women and children, singing it after the sermons at St Paul's Cross—adding, "Id sacrificos et diabolum aegre habet; vident enim sacras conciones hoc pacto profundius descendere in hominum animos." The first edition of the completed "Old Version" (containing forty Psalms by Sternhold, sixty-seven by Hopkins, fifteen by Whittingham, six by Kethe and the rest by Thomas Norton the dramatist, Robert Wisdom, John Marckant and Thomas Churchyard) appeared in 1562.

Sternhold and Hopkins.

In the meantime, the Books of Common Prayer, of 1549, 1552 and 1559, had been successively established as law by the acts of uniformity of Edward VI. and Queen Elizabeth. In these no provision was made for the use of any metrical psalm or hymn on any occasion whatever, except at the consecration of bishops and the ordination of priests, in which offices (first added in 1552) an English version of "Veni Creator" (the longer of the two now in use) was appointed to be "said or sung." The canticles, "Te Deum," "Benedicite," the Nicene and Athanasian Creeds, the "Gloria in Excelsis," and some other parts of the communion and other special offices were also directed to be "said or sung"; and, by general rubrics, the chanting of the whole service was allowed.

The silence, however, of the rubrics in these books as to any other singing was not meant to exclude the use of psalms not expressly appointed, when they could be used without interfering with the prescribed order of any service. It was expressly provided by King Edward's first act of uniformity (by later acts made applicable to the later books) that it should be lawful "for all men, as well in churches, chapels, oratories or other places, to use openly any psalms or prayers taken out of the Bible, at any due time, not letting or omitting thereby the service, or any part thereof, mentioned in the book." And Queen Elizabeth, by one of the injunctions issued in the first year of her reign, declared her desire that the provision made, "in divers collegiate and also some parish churches, for singing in the church, so as to promote the laudable service of music," should continue. After allowing the use of "a modest and distinct song in all parts of the common prayers of the church, so that the same may be as plainly understanded as if it were read without singing," the injunction proceeded thus—"And yet, nevertheless, for the comforting of such that delight in music, it may be permitted that in the beginning or in the end of the Common Prayer, either at morning or evening, there may be sung an hymn, or such like song to the praise of Almighty God, in the best sort of melody and music that may be conveniently devised, having respect that the sentence" (*i.e.* sense) "of hymn may be understanded and perceived."

The "Old Version," when published (by John Daye, for the Stationers' Company, "cum gratia et privilegio Regiae Majestatis"), bore upon the face of it that it was "newly set forth, and allowed to be sung of the people in churches, before and after morning and evening prayer, as also before and after the sermon." The question of its authority has been at different times much debated, chiefly by Peter Heylyn and Thomas Warton on one side (both of whom disliked and disparaged it), and by William Beveridge, bishop of St Asaph, and the Rev. H. J. Todd on the other. Heylyn says, it was "permitted rather than allowed," which seems to be a distinction without much difference. "Allowance," which is all that the book claimed for itself, is authorization by way of permission, not of commandment. Its publication in that form could hardly have been licensed, nor could it have passed into use as it did without question, throughout the churches of England, unless it had been "allowed" by some authority then esteemed to be sufficient. Whether that authority was royal or ecclesiastical does not appear, nor (considering the proviso in King Edward's act of uniformity, and Queen Elizabeth's injunctions) is it very important. No inference can justly be drawn from the inability of inquirers, in Heylyn's time or since, to discover any public record bearing upon this subject, many public documents of that period having been lost.

In this book, as published in 1562, and for many years afterwards, there were (besides the versified Psalms) eleven metrical versions of the "Te Deum," canticles, Lord's Prayer (the best of which is that of the "Benedicite"); and also "Da pacem, Domine," a hymn suitable to the times, rendered into English from Luther; two original hymns of praise, to be sung before morning and evening prayer; two penitential hymns (one of them the "humble lamentation of a sinner"); and a hymn of faith, beginning, "Lord, in Thee is all my trust." In these respects, and also in the tunes which accompanied the words (stated by Dr Charles Burney, in his *History of Music*, to be German, and not French), there was a departure from the Genevan platform. Some of these hymns, and some of the psalms also (*e.g.* those by Robert Wisdom, being alternative versions), were omitted at a later period; and many alterations and supposed amendments were from time to time made by unknown hands in the psalms which remained, so that the text, as now printed, is in many places different from that of 1562.

In Scotland, the General Assembly of the kirk caused to be printed at Edinburgh in 1564, and enjoined the use of, a book entitled *The Form of Prayers and Ministry of the Sacraments used in the English Church at Geneva, approved and received by the Church of Scotland; whereto, besides that was in the former books, are also added sundry other prayers, with the whole Psalms of David in English metre.* This contained, from the "Old Version," translations of forty Psalms by Sternhold, fifteen by Whittingham, twenty-six by Kethe and thirty-five by Hopkins. Of the remainder two were by John Pulleyn (one of the Genevan refugees, who became archdeacon of Colchester); six by Robert Pont, Knox's son-in-law, who was a minister of the kirk, and also a lord of session; and fourteen signed with the initials I. C., supposed to be John Craig; one was anonymous, eight were attributed to N., two to M. and one to T. N. respectively.

Scotch Psalms.

So matters continued in both churches until the Civil War. During the interval, King James I. conceived the project of himself making a new version of the Psalms, and appears to have translated thirty-one of them—the correction of which, together with the translation of the rest, he entrusted to Sir William Alexander, afterwards earl of Stirling. Sir William having completed his task, King Charles I. had it examined and approved by several archbishops and bishops of England, Scotland and Ireland, and caused it to be printed in 1631 at the Oxford University Press, as the work of King James; and, by an order under the royal sign manual, recommended its use in all churches of his dominions. In 1634 he enjoined the Privy Council of Scotland not to suffer any other psalms, "of any edition whatever," to be printed in or imported into that kingdom. In 1636 it was republished, and was attached to the famous Scottish service-book, with which the troubles began in 1637. It need hardly be added that the king did not succeed in bringing this Psalter into use in either kingdom.

When the Long Parliament undertook, in 1642, the task of altering the liturgy, its attention was at the same time directed to psalmody. It had to judge between two rival translations of the Psalms—one by Francis Rouse, a member of the House of Commons, afterwards one of Cromwell's councillors and finally provost of Eton; the other by William Barton, a clergyman of Leicester. The House of Lords favoured Barton, the House of Commons Rouse, who had made much use of the labours of Sir William Alexander. Both versions were printed by order of parliament, and were referred for consideration to the Westminster Assembly. They decided in favour of Rouse. His version, as finally amended, was published in 1646, under an order of the House of Commons dated 14th November 1645. In the following year it was recommended by the parliament to the General Assembly at Edinburgh, who appointed a committee, with large powers, to prepare a revised Psalter, recommending to their consideration not only Rouse's book but that of 1564, and two other versions (by Zachary Boyd and Sir William Mure of Rowallan), then lately executed in Scotland. The result of the labours of this committee was the "Paraphrase" of the Psalms, which, in 1649–1650, by the concurrent authority of the General Assembly and the committee of estates, was ordered to be exclusively used throughout the church of Scotland. Some use was made in the preparation of this book of the versions to which the attention of the revisers had been directed, and also of Barton's; but its basis was that of Rouse. It was received in Scotland with great favour, which it has ever since retained; and it is fairly entitled to the praise of striking a tolerable medium between the rude homeliness of the "Old," and the artificial modernism of the "New" English versions—perhaps as great a success as was possible for such an undertaking. Sir Walter Scott is said to have dissuaded any attempt to alter it, and to have pronounced it, "with all its acknowledged occasional harshness, so beautiful, that any alterations must eventually prove only so many blemishes." No further step towards any authorized hymnody was taken by the kirk of Scotland till the following century.

In England, two changes bearing on church hymnody were made upon the revision of the prayer-book after the Restoration, in 1661–1662. One was the addition, in the offices for consecrating bishops and ordaining priests, of the shorter version of "Veni Creator" ("Come, Holy Ghost, our souls inspire"), as an alternative form. The other, and more important, was the insertion of the rubric after the third collect, at morning and evening prayer: "In quires and places where they sing, here followeth the anthem." By this rubric synodical and parliamentary authority was given for the interruption, at that point, of the prescribed order of the service by singing an anthem, the choice of which was left to the discretion of the minister. Those actually used, under this authority, were for some time only unmetrical passages of scripture, set to music by Blow, Purcell and other composers, of the same kind with the anthems still generally sung in cathedral and collegiate churches. But the word "anthem" had no technical signification which could be an obstacle to the use under this rubric of metrical hymns.

Tate and Brady.

The "New Version" of the Psalms, by Dr Nicholas Brady and the poet-laureate Nahum Tate (both Irishmen), appeared in 1696, under the sanction of an order in council of William III., "allowing and permitting" its use "in all such churches, chapels and congregations as should think fit to receive it." Dr Compton, bishop of London, recommended it to his diocese. No hymns were then appended to it; but the authors added a "supplement" in 1703, which received an exactly similar sanction from an order in council of Queen Anne. In that supplement there were several new versions of the canticles, and of the "Veni Creator"; a variation of the old "humble lamentation of a sinner"; six hymns for Christmas, Easter and Holy Communion (all versions or paraphrases of scripture), which are still usually printed at the end of the prayer-books containing the new version; and a hymn "on the divine use of music"—all accompanied by tunes. The authors also reprinted, with very good taste, the excellent version of the "Benedicite" which appeared in the book of 1562. Of the hymns in this "supplement," one ("While shepherds watched their flocks by night") greatly exceeded the rest in merit. It has been ascribed to Tate, but it has a character of simplicity unlike the rest of his works.

Old and new versions compared.

The relative merits of the "Old" and "New" versions have been very variously estimated. Competent judges have given the old the praise, which certainly cannot be accorded to the new, of fidelity to the Hebrew. In both, it must be admitted, that those parts which have poetical merit are few and far between; but a reverent taste is likely to be more offended by the frequent sacrifice, in the new, of depth of tone and accuracy of sense to a fluent commonplace correctness of versification and diction, than by any excessive homeliness in the old. In both, however, some psalms, or portions of psalms, are well enough rendered to entitle them to a permanent place in the hymn-books—especially the 8th, and parts of the 18th Psalm, by Sternhold; the 57th, 84th and 100th, by Hopkins; the 23rd, 34th and 36th, and part of the 148th, by Tate and Brady.

The judgment which a fastidious critic might be disposed to pass upon both these books may perhaps be considerably mitigated by comparing them with the works of other labourers in the same field, of whom Holland, in his interesting volumes entitled *Psalmists of Great Britain*, enumerates above 150. Some of them have been real poets—the celebrated earl of Surrey, Sir Philip Sidney and his sister the countess of Pembroke, George Sandys, George Wither, John Milton and John Keble. In their versions, as might be expected, there are occasional gleams of power and beauty, exceeding anything to be found in Sternhold and Hopkins, or Tate and Brady; but even in the best these are rare, and chiefly occur where the strict idea of translation has been most widely departed from. In all of them, as a rule, the life and spirit, which in prose versions of the psalms are so wonderfully preserved, have disappeared. The conclusion practically suggested by so many failures is that the difficulties of metrical translation, always great, are in this case insuperable; and that, while the psalms like other parts of scripture are abundantly suggestive of motive and material for hymnographers, it is by assimilation and adaptation, and not by any attempt to transform their exact sense into modern poetry, that they may be best used for this purpose.

The order in council of 1703 is the latest act of any public authority by which an express sanction has been given to the use of psalms or hymns in the Church of England. At the end, indeed, of many Prayer-books, till about the middle of the 19th century, there were commonly found, besides some of the hymns sanctioned by that order in council, or of those contained in the book of 1562, a sacramental and a Christmas hymn by Doddridge; a Christmas hymn (varied by Martin Madan) from Charles Wesley; an Easter hymn of the 18th century, beginning "Jesus Christ has risen to-day"; and abridgments of Bishop Ken's Morning and Evening Hymns. These additions first began to be made in or about 1791, in London editions of the Prayer-book and Psalter, at the mere will and pleasure (so far as appears) of the printers. They had no sort of authority.

English congregational hymnody.

In the state of authority, opinion and practice disclosed by the preceding narrative may be found the true explanation of the fact that, in the country of Chaucer, Spenser, Shakespeare and Milton, and notwithstanding the example of Germany, no native congregational hymnody worthy of the name arose till after the commencement of the 18th century. Yet there was no want of appreciation of the power and value of congregational church music. Milton could write, before 1645:—

"There let the pealing organ blow
To the full-voiced quire below
In service high, and anthems clear,
As may with sweetness through mine ear
Dissolve me into ecstasies,
And bring all Heaven before mine eyes."

Thomas Mace, in his *Music's Monument* (1676), thus described the effect of psalm-singing before sermons by the congregation in York Minster on Sundays, during the siege of 1644: "When that vast concording unity of the whole congregational chorus came thundering in, even so as it made the very ground shake under us, oh, the unutterable ravishing soul's delight! in the which I was so transported and wrapt up in high contemplations that there was no room left in my whole man, body, soul and spirit, for anything below divine and heavenly raptures; nor could there possibly be anything to which that very singing might be truly compared, except the right apprehension or conceiving of that glorious and miraculous quire, recorded in the scriptures at the dedication of the temple." Nor was there any want of men well qualified, and by the turn of their minds predisposed, to shine in this branch of literature. Some (like Sandys, Boyd and Barton) devoted themselves altogether to paraphrases of other scriptures as well as the psalms. Others (like George Herbert, and Francis and John Quarles) moralized, meditated, soliloquized and allegorized in verse. Without reckoning these, there were a few, even before the Restoration, who came very near to the ideal of hymnody.

Wedderburn. First in time is the Scottish poet John Wedderburn, who translated several of Luther's hymns, and in his *Compendious Book of Godly and Spiritual Songs* added others of his own (or his brothers') composition. Some of these poems, published before 1560, are of uncommon excellence, uniting ease and melody of rhythm, and structural skill, with grace of expression, and simplicity, warmth and reality of religious feeling. Those entitled "Give me thy heart," "Go, heart," and "Leave me not," which will be found in a collection of 1860 called *Sacred Songs of Scotland*, require little, beyond the change of some archaisms of language, to adapt them for church or domestic use at the present day.

Dickson. Next come the two hymns of "The new Jerusalem," by an English Roman Catholic priest signing himself F. B. P. (supposed to be "Francis Baker, Presbyter"), and by another Scottish poet, David Dickson, of which the history is given by Dr Bonar in his edition of Dickson's work. This (Dickson's), which begins "O mother dear, Jerusalem," and has long been popular in Scotland, is a variation and amplification by the addition of a large number of new stanzas of the English original, beginning "Jerusalem, my happy home," written in Queen Elizabeth's time, and printed (as appears by a copy in the British Museum) about 1616, when Dickson was still young. Both have an easy natural flow, and a simple happy rendering of the beautiful scriptural imagery upon the subject, with a spirit of primitive devotion uncorrupted by medieval peculiarities. The English hymn of which some stanzas are now often sung in churches is the true parent of the several shorter forms,—all of more than common merit,—which, in modern hymn-books, begin with the same first line, but afterwards deviate from the original. Kindred to these is the very fine and faithful translation, by Dickson's contemporary Drummond of Hawthornden of the ancient "Urbs beata Hierusalem" ("Jerusalem, that place divine"). Other ancient hymns (two of Thomas Aquinas, and the "Dies Irae") were also well translated, in 1646, by Richard Crashaw, after he had become a Roman Catholic and had been deprived by the parliament of his fellowship at Cambridge.

Wither. Conspicuous among the sacred poets of the first two Stuart reigns in England was George Wither. His *Hymnes and Songs of the Church* appeared in 1622–1623, under a patent of King James I., by which they were declared "worthy and profitable to be inserted, in convenient manner and due place, into every English Psalm-book to metre." His *Hallelujah* (in which some of the former *Hymnes and Songs* were repeated) followed in 1641. Some of the *Hymnes and Songs* were set to music by Orlando Gibbons, and those in both books were written to be sung, though there is no evidence that the author contemplated the use of any of them in churches. They included hymns for every day in the week (founded, as those contributed nearly a century afterwards by Charles Coffin to the Parisian Breviary also were, upon the successive works of the days of creation); hymns for all the church seasons and festivals, including saints' days; hymns for various public occasions; and hymns of prayer, meditation and instruction, for all sorts and conditions of men, under a great variety of circumstances — being at once a "Christian Year" and a manual of practical piety. Many of them rise to a very high point of excellence,—particularly the "general invitation to praise God" ("Come, O come, in pious lays"), with which *Hallelujah* opens; the thanksgivings for peace and for victory, the Coronation Hymn, a Christmas, an Epiphany, and an Easter Hymn, and one for St Bartholomew's day (Hymns 1, 74, 75, and 84 in part i., and 26, 29, 36 and 54 in part ii. of *Hallelujah*).

Cosin. John Cosin, afterwards bishop of Durham, published in 1627 a volume of "Private Devotions," for the canonical hours and other occasions. In this there are seven or eight hymns of considerable merit,—among them a very good version of the Ambrosian "Jam lucis orto sidere," and the shorter version of the "Veni Creator," which was introduced after the Restoration into the consecration and ordination services of the Church of England.

Milton. The hymns of Milton (on the Nativity, Passion, Circumcision and "at a Solemn Music"), written about 1629, in his early manhood, were probably not intended for singing; but they are odes full of characteristic beauty and power.

Jeremy Taylor. During the Commonwealth, in 1654, Jeremy Taylor published at the end of his *Golden Grove*, twenty-one hymns, described by himself as "celebrating the mysteries and chief festivals of the year, according to the manner of the ancient church, fitted to the fancy and devotion of the younger and pious persons, apt for memory, and to be joined to their other prayers." Of these, his accomplished editor, Bishop Heber, justly says:—

"They are in themselves, and on their own account, very interesting compositions. Their metre, indeed, which is that species of spurious Pindaric which was fashionable with his contemporaries, is an obstacle, and must always have been one, to their introduction into public or private psalmody; and the mixture of that alloy of conceits and quibbles which was an equally frequent and still greater defilement of some of the finest poetry of the 17th century will materially diminish their effect as devotional or descriptive odes. Yet, with all these faults, they are powerful, affecting, and often harmonious; there are many passages of which Cowley need not have been ashamed, and some which remind us, not disadvantageously, of the corresponding productions of Milton."

He mentions particularly the advent hymn ("Lord, come away"), part of the hymn "On heaven," and (as "more regular in metre, and in words more applicable to public devotion") the "Prayer for Charity" ("Full of mercy, full of love").

Restoration period. The epoch of the Restoration produced in 1664 Samuel Crossman's *Young Man's Calling*, with a few "Divine Meditations" in verse attached to it; in 1668 John Austin's *Devotions in the ancient way of offices, with psalms, hymns and prayers for every day in the week and every holyday in the year*; and in 1681 Richard Baxter's *Poetical Fragments*. In these books there are altogether seven or eight hymns, the whole or parts of which are extremely good: Crossman's "New Jerusalem" ("Sweet place, sweet place alone"), one of the best of that class, and "My life's a shade, my days"; Austin's "Hark, my soul, how everything," "Fain would my thoughts fly up to Thee," "Lord, now the time returns," "Wake all my hopes, lift up your eyes"; and Baxter's "My whole, though broken heart, O Lord," and "Ye holy angels bright." Austin's *Offices* (he was a Roman Catholic) seem to have attracted much attention. Theophilus Dorrington, in 1686, published variations of them under the title of *Reformed*

Devotions; George Hickes, the non-juror, wrote one of his numerous recommendatory prefaces to S. Hopton's edition; and the Wesleys, in their earliest hymn-book, adopted hymns from them, with little alteration. These writers were followed by John Mason in 1683, and Thomas Shepherd in 1692,—the former, a country clergyman, much esteemed by Baxter and other Nonconformists; the latter himself a Nonconformist, who finally emigrated to America. Between these two men there was a close alliance, Shepherd's *Penitential Cries* being published as an addition to the *Spiritual Songs* of Mason. Their hymns came into early use in several Nonconformist congregations; but, with the exception of one by Mason ("There is a stream which issues forth"), they are not suitable for public singing. In those of Mason there is often a very fine vein of poetry; and later authors have, by extracts or centoes from different parts of his works (where they were not disfigured by his general quaintness), constructed several hymns of more than average excellence.

Three other eminent names of the 17th century remain to be mentioned, John Dryden, Bishop Ken and Bishop Simon Patrick; with which may be associated that of Addison, though he wrote in the 18th century.

Dryden's translation of "Veni Creator" a cold and laboured performance, is to be met with in many hymn-books. Abridgments of Ken's morning and evening hymns are in all. These, with the midnight hymn, which is not inferior to them, first appeared in 1697, appended to the third edition of the author's *Manual of Prayers for Winchester Scholars*. Between these and a large number of other hymns (on the attributes of God, and for the festivals of the church) published by Bishop Ken after 1703 the contrast is remarkable. The universal acceptance of the morning and evening hymns is due to their transparent simplicity, warm but not overstrained devotion, and extremely popular style. Those afterwards published have no such qualities. They are mystical, florid, stiff, didactic and seldom poetical, and deserve the neglect into which they have fallen. Bishop Patrick's hymns were chiefly translations from the Latin, most of them from Prudentius. The best is a version of "Alleluia dulce carmen." Of the five attributed to Addison, not more than three are adapted to public singing; one ("The spacious firmament on high") is a very perfect and finished composition, taking rank among the best hymns in the English language.[1]

Dryden, Ken. **Patrick.** **Addison.**

From the preface to Simon Browne's hymns, published in 1720, we learn that down to the time of Dr Watts the only hymns known to be "in common use, either in private families or in Christian assemblies," were those of Barton, Mason and Shepherd, together with "an attempt to turn some of George Herbert's poems into common metre," and a few sacramental hymns by authors now forgotten, named Joseph Boyse (1660–1728) and Joseph Stennett. Of the 1410 authors of original British hymns enumerated in Daniel Sedgwick's catalogue, published in 1863, 1213 are of later date than 1707; and, if any correct enumeration could be made of the total number of hymns of all kinds published in Great Britain before and after that date, the proportion subsequent to 1707 would be very much larger.

[1] The authorship of this and of one other, "When all thy mercies, O my God," has been made a subject of controversy,—being claimed for Andrew Marvell (who died in 1678), in the preface to Captain E. Thompson's edition (1776) of Marvell's *Works*. But this claim does not appear to be substantiated. The editor did not give his readers the means of judging as to the real age, character or value of a manuscript to which he referred; he did not say that these portions of it were in Marvell's handwriting; he did not even himself include them among Marvell's poems, as published in the body of his edition; and he advanced a like claim on like grounds to two other poems, in very different styles, which had been published as their own by Tickell and Mallet. It is certain that all the five hymns were first made public in 1712, in papers contributed by Addison to the *Spectator* (Nos. 441, 453, 465, 489, 513), in which they were introduced in a way which might have been expected if they were by the hand which wrote those papers, but which would have been improbable, and unworthy of Addison, if they were unpublished works of a writer of so much genius, and such note in his day, as Marvell. They are all printed as Addison's in Dr Johnson's *British Poets*.

The English Independents, as represented by Dr Isaac Watts, have a just claim to be considered the real founders of modern English hymnody. Watts was the first to understand the nature of the want, and, by the publication of his *Hymns* in 1707–1709, and *Psalms* (not translations, but hymns founded on psalms) in 1709, he led the way in providing for it. His immediate followers were Simon Browne and Philip Doddridge. Later in the 18th century, Joseph Hart, Thomas Gibbons, Miss Anne Steele, Samuel Medley, Samuel Stennett, John Ryland, Benjamin Beddome and Joseph Swain succeeded to them.

Among these writers, most of whom produced some hymns of merit, and several are extremely voluminous, Isaac Watts and Philip Doddridge are pre-eminent. It has been the fashion with some to disparage Watts, as if he had never risen above the level of his *Hymns for Little Children*. No doubt his taste is often faulty, and his style very unequal, but, looking to the good, and disregarding the large quantity of inferior matter, it is probable that more hymns which approach to a very high standard of excellence, and are at the same time suitable for congregational use, may be found in his works than in those of any other English writer. Such are "When I survey the wondrous cross," "Jesus shall reign where'er the sun" (and also another adaptation of the same 72nd Psalm), "Before Jehovah's awful throne" (first line of which, however, is not his, but Wesley's), "Joy to the world, the Lord is come," "My soul, repeat His praise," "Why do we mourn departing friends," "There is a land of pure delight," "Our God, our help in ages past," "Up to the hills I lift mine eyes," and many more. It is true that in some of these cases dross is found in the original poems mixed with gold; but the process of separation, by selection without change, is not difficult. As long as pure nervous English, unaffected fervour, strong simplicity and liquid yet manly sweetness are admitted to be characteristics of a good hymn, works such as these must command admiration.

Watts.

Doddridge is, generally, much more laboured and artificial; but his place also as a hymn-writer ought to be determined, not by his failures, but by his successes, of which the number is not inconsiderable. In his better works he is distinguished by a graceful and pointed, sometimes even a noble style. His "Hark, the glad sound, the Saviour comes" (which is, indeed, his masterpiece), is as sweet, vigorous and perfect a composition as can anywhere be found. Two other hymns, "How gentle God's commands," and that which, in a form slightly varied, became the "O God of Bethel, by whose hand," of the Scottish "Paraphrases," well represent his softer manner.

Doddridge.

Of the other followers in the school of Watts, Miss Anne Steele (1717–1778) is the most popular and perhaps the best. Her hymn beginning "Far from these narrow scenes of night" deserves high praise, even by the side of other good performances on the same subject.

The influence of Watts was felt in Scotland, and among the first whom it reached there was Ralph Erskine. This seems to have been after the publication of Erskine's *Gospel Sonnets*, which appeared in 1732, five years before he joined his brother Ebenezer in the Secession Church. The *Gospel Sonnets* became, as some have said, a "people's classic"; but there is in them very little which belongs to the category of hymnody. More than nineteen-twentieths of this very curious book are occupied with what are, in fact, theological treatises and catechisms, mystical meditations on Christ as a bridegroom or husband, and spiritual enigmas, paradoxes, and antithetical conceits, versified, it is true, but of a quality of which such lines as—

"Faith's certain by fiducial acts,
Sense by its evidential facts,"

may be taken as a sample. The grains of poetry scattered through this large mass of Calvinistic divinity are very few; yet in one short passage of seven stanzas ("O send me down a draught of love"), the fire burns with a brightness so remarkable as to justify a strong feeling of regret that the gift which this writer evidently had in him was not more often cultivated. Another passage, not so well sustained, but of considerable beauty (part of the last piece under the title "The believer's soliloquy"), became afterwards, in the hands of John Berridge, the foundation of a very striking hymn ("O happy saints, who walk in light").

After his secession, Ralph Erskine published two paraphrases of the "Song of Solomon," and a number of other "Scripture songs," paraphrased, in like manner, from the Old and New Testaments. In these the influence of Watts became very apparent, not only by a change in the writer's general style, but by the direct appropriation of no small quantity of matter from Dr Watts's hymns, with variations which were not always improvements. His paraphrases of 1 Cor. i. 24; Gal. vi. 14; Heb. vi. 17-19; Rev. v. 11, 12, vii. 10-17, and xii. 7-12 are little else than Watts transformed. One of these (Rev. vii. 10-17) is interesting as a variation and improvement, intermediate between the original and the form which it ultimately assumed as the 66th "Paraphrase" of the Church of Scotland, of Watts's "What happy men or angels these," and "These glorious minds, how bright they shine." No one can compare it with its ultimate product, "How bright these glorious spirits shine," without perceiving that William Cameron followed Erskine, and only added finish and grace to his work,—both excelling Watts, in this instance, in simplicity as well as in conciseness.

Scottish paraphrases.

Of the contributions to the authorized "Paraphrases" (with the settlement of which committees of the General Assembly of the Church of Scotland were occupied from 1745, or earlier, till 1781), the most noteworthy, besides the two already mentioned, were those of John Morrison and those claimed for Michael Bruce. The obligations of these "Paraphrases" to English hymnody, already traced in some instances (to which may be added the adoption from Addison of three out of the five "hymns" appended to them), are perceptible in the vividness and force with which these writers, while adhering with a severe simplicity to the sense of the passages of Scripture which they undertook to render, fulfilled the conception of a good original hymn. Morrison's "The race that long in darkness pined" and "Come, let us to the Lord our God," and Bruce's "Where high the heavenly temple stands" (if this was really his), are well entitled to that praise. The advocates of Bruce in the controversy, not yet closed, as to the poems said to have been entrusted by him to John Logan, and published by Logan in his own name, also claim for him the credit of having varied the paraphrase "Behold, the mountain of the Lord," from its original form, as printed by the committee of the General Assembly in 1745, by some excellent touches.

Methodist hymns.

Attention must now be directed to the hymns produced by the "Methodist" movement, which began about 1738, and which afterwards became divided, between those esteemed Arminian, under John Wesley, those who adhered to the Moravians, when the original alliance between that body and the founders of Methodism was dissolved, and the Calvinists, of whom Whitfield was the leader, and Selina, countess of Huntingdon, the patroness. Each of these sections had its own hymn-writers, some of whom did, and others did not, secede from the Church of England. The Wesleyans had Charles Wesley, Robert Seagrave and Thomas Olivers; the Moravians, John Cennick, with whom, perhaps, may be classed John Byrom, who imbibed the mystical ideas of some of the German schools; the Calvinists, Augustus Montague Toplady, John Berridge, William Williams, Martin Madan, Thomas Haweis, Rowland Hill, John Newton and William Cowper.

Charles Wesley.

Among all these writers, the palm undoubtedly belongs to Charles Wesley. In the first volume of hymns published by the two brothers are several good translations from the German, believed to be by John Wesley, who, although he translated and adapted, is not supposed to have written any original hymns; and the influence of German hymnody, particularly of the works of Paul Gerhardt, Scheffler, Tersteegen and Zinzendorf, may be traced in a large proportion of Charles Wesley's works. He is more subjective and meditative than Watts and his school; there is a didactic turn, even in his most objective pieces, as, for example, in his Christmas and Easter hymns; most of his works are supplicatory, and his faults are connected with the same habit of mind. He is apt to repeat the same thoughts, and to lose force by redundancy—he runs sometimes even to a tedious length; his hymns are not always symmetrically constructed, or well balanced and finished off. But he has great truth, depth and variety of feeling; his diction is manly and always to the point; never florid, though sometimes passionate and not free from exaggeration; often vivid and picturesque. Of his spirited style there are few better examples than "O for a thousand tongues to sing," "Blow ye the trumpet, blow," "Rejoice, the Lord is King" and "Come, let us join our friends above"; of his more tender vein, "Happy soul, thy days are ended"; and of his fervid contemplative style (without going beyond hymns fit for general use), "O Thou who camest from above," "Forth in Thy name, O Lord, I go" and "Eternal beam of light divine." With those whose taste is for hymns in which warm religious feelings are warmly and demonstratively expressed, "Jesus, lover of my soul," is as popular as any of these.

Olivers.

Of the other Wesleyan hymn-writers, Olivers, originally a Welsh shoemaker and afterwards a preacher, is the most remarkable. He is the author of only two works, both odes, in a stately metre, and from their length unfit for congregational singing, but one of them, "The God of Abraham praise," an ode of singular power and beauty.

Cennick, Hammond, Byrom.

The Moravian Methodists produced few hymns now available for general use. The best are Cennick's "Children of the heavenly King" and Hammond's "Awake and sing the song of Moses and the Lamb," the former of which (abridged), and the latter as varied by Madan, are found in many hymn-books, and are deservedly esteemed. John Byrom, whose name we have thought it convenient to connect with these, though he did not belong to the Moravian community, was the author of a Christmas hymn ("Christians awake, salute the happy morn") which enjoys great popularity; and also of a short subjective hymn, very fine both in feeling and in expression, "My spirit longeth for Thee within my troubled breast."

Toplady.

The contributions of the Calvinistic Methodists to English hymnody are of greater extent and value. Few writers of hymns had higher gifts than Toplady, author of "Rock of ages," by some esteemed the finest in the English language. He was a man of ardent temperament, enthusiastic zeal, strong convictions and great energy of character. "He had," says one of his biographers, "the courage of a lion, but his frame was brittle as glass." Between him and John Wesley there was a violent opposition of opinion, and much acrimonious controversy; but the same fervour and zeal which made him an intemperate theologian gave warmth, richness and spirituality to his hymns. In some of them, particularly those which, like "Deathless principle, arise," are meditations after the German manner, and not without direct obligation to German originals, the setting is somewhat too artificial; but his art is never inconsistent with a genuine flow of real feeling. Others (*e.g.* "When languor and disease invade" and "Your harps, ye trembling saints") fail to sustain to the end the beauty with which they began, and would have been better for abridgment. But in all these, and in most of his other works, there is great force and sweetness, both of thought and language, and an easy and harmonious versification.

Berridge, Williams and R. Hill.

Berridge, William Williams (1717–1791) and Rowland Hill, all men remarkable for eccentricity, activity and the devotion of their lives to the special work of missionary preaching, though not the authors of many good hymns, composed, or adapted from earlier compositions, some of great merit. One of Berridge, adapted from Erskine, has been already mentioned; another, adapted from Watts, is "Jesus, cast a look on me." Williams, a Welshman, who wrote "Guide me, O Thou great Jehovah," was especially an apostle of Calvinistic Methodism in his own country, and his hymns are still much used in the principality. Rowland Hill wrote the popular hymn beginning "Exalted high at God's right hand."

If, however, the number as well as the quality of good hymns available for general use is to be regarded, the authors of the *Olney Hymns* are entitled to be placed at the head of all the writers of this Calvinistic school. The greater number of the *Olney Hymns* are, no doubt, homely and didactic; but to the best of them, and they are no inconsiderable proportion, the tenderness of Cowper and the manliness of John Newton (1725–1807) give the interest of contrast, as well as that of sustained reality. If Newton carried to some excess the sound principle laid down by him, that "perspicuity, simplicity and ease should be chiefly attended to, and the imagery and colouring of poetry, if admitted at all, should be indulged very sparingly and with great judgment," if he is often dry and colloquial, he rises at other times into "soul-animating strains," such as "Glorious things of thee are spoken, Zion, city of our God"; and sometimes (as in "Approach, my soul, the mercy seat") rivals Cowper himself in depth of feeling. Cowper's hymns in this book are, almost without exception, worthy of his name. Among them are "Hark, my soul, it is the Lord," "There is a fountain filled with blood," "Far from the world, O Lord, I flee," "God moves in a mysterious way" and "Sometimes a light surprises." Some, perhaps, even of these, and others of equal excellence (such as "O for a closer walk with God"), speak the language of a special experience, which, in Cowper's case, was only too real, but which could not, without a degree of unreality not desirable in exercises of public worship, be applied to themselves by all ordinary Christians.

Cowper and Newton.

During the first quarter of the 19th century there were not many indications of the tendency, which afterwards became manifest, to enlarge the boundaries of British hymnody. *The Remains of Henry Kirke White*, published by Southey in 1807, contained a series of hymns, some of which are still in use; and a few of Bishop Heber's hymns and those of Sir Robert Grant, which, though offending rather too much against John Newton's canon, are well known and popular, appeared between 1811 and 1816, in the *Christian Observer*. In John Bowdler's *Remains*, published soon after his death in 1815, there are a few more of the same, perhaps too scholarlike, character. But the chief hymn-writers of that period were two clergymen of the Established Church—one in Ireland, Thomas Kelly, and the other in England, William Hurn—who both became Nonconformists, and the Moravian poet, James Montgomery (1771–1854), a native of Scotland.

19th-century hymns.

R. Grant.

Bowdler.

Kelly was the son of an Irish judge, and in 1804 published a small volume of ninety-six hymns, which grew in successive editions till, in the last before his death in 1854, they amounted to 765. There is, as might be expected, in this great number a large preponderance of the didactic and commonplace. But not a few very excellent hymns may be gathered from them. Simple and natural, without the vivacity and terseness of Watts or the severity of Newton, Kelly has some points in common with both those writers, and he is less subjective than most of the "Methodist" school. His hymns beginning "Lo! He comes, let all adore Him," and "Through the day Thy love hath spared us," have a rich, melodious movement; and another, "We sing the praise of Him who died," is distinguished by a calm, subdued power, rising gradually from a rather low to a very high key.

Kelly.

Hurn published in 1813 a volume of 370 hymns, which were afterwards increased to 420. There is little in them which deserves to be saved from oblivion; but one at least, "There is a river deep and broad," may bear comparison with the best of those which have been produced upon the same, and it is rather a favourite, theme.

Hurn.

The *Psalms and Hymns* of James Montgomery were published in 1822 and 1825, though written earlier. More cultivated and artistic than Kelly, he is less simple and natural. His "Hail to the Lord's Anointed," "Songs of praise the angels sang" and "Mercy alone can meet my case" are among his most successful efforts.

Montgomery.

During this period, the collections of miscellaneous hymns for congregational use, of which the example was set by the Wesleys, Whitfield, Toplady and Lady Huntingdon, had greatly multiplied; and with them the practice (for which, indeed, too many precedents existed in the history of Latin and German hymnody) of every collector altering the compositions of other men without scruple, to suit his own doctrine or taste; with the effect, too generally, of patching and disfiguring, spoiling and emasculating the works so altered, substituting neutral tints for natural colouring, and a dead for a living sense. In the Church of England the use of these collections had become frequent in churches and chapels, principally in cities and towns, where the sentiments of the clergy approximated to those of the Nonconformists. In rural parishes, when the clergy were not of the "Evangelical" school, they were generally held in disfavour; for which, even if doctrinal prepossessions had not entered into the question, the great want of taste and judgment often manifested in their compilation, and perhaps also the prevailing mediocrity of the bulk of the original compositions from which most of them were derived, would be enough to account. In addition to this, the idea that no hymns ought to be used in any services of the Church of England, except prose anthems after the third collect, without express royal or ecclesiastical authority, continued down to that time largely to prevail among high churchmen.

Collections of hymns.

Two publications, which appeared almost simultaneously in 1827—Bishop Heber's *Hymns*, with a few added by Dean Milman, and John Keble's *Christian Year* (not a hymn-book, but one from which several admirable hymns have been taken, and the well-spring of many streams of thought and feeling by which good hymns have since been produced)—introduced a new epoch, breaking down the barrier as to hymnody which had till then existed between the different theological schools of the Church of England. In this movement Richard Mant, bishop of Down, was also one of the first to co-operate. It soon received a great additional impulse from the increased attention which, about the same time, began to be paid to ancient hymnody, and from the publication in 1833 of Bunsen's *Gesangbuch*. Among its earliest fruits was the *Lyra apostolica*, containing hymns, sonnets and other devotional poems, most of them originally contributed by some of the leading authors of the *Tracts for the Times* to the *British Magazine*; the finest of which is the pathetic "Lead, kindly Light, amid th' encircling gloom," by Cardinal Newman—well known, and universally admired. From that time hymns and hymn-writers rapidly multiplied in the Church of England, and in Scotland also. Nearly 600 authors whose publications were later than 1827 are enumerated in Sedgwick's catalogue of 1863, and about half a million hymns are now in existence. Works, critical and historical, upon the subject of hymns, have also multiplied; and collections for church use have become innumerable—several of the various religious denominations, and many of the leading ecclesiastical and religious societies, having issued hymn-books of their own, in addition to those compiled for particular dioceses, churches and chapels, and to books (like *Hymns Ancient and Modern*, published 1861, supplemented 1889, revised edition, 1905) which have become popular without any sanction from authority. To mention all the authors of good hymns since the commencement of this new epoch would be impossible; but probably no names could be chosen more fairly representative of its characteristic merits, and perhaps also of some of its defects, than those of Josiah Conder and James Edmeston among English Nonconformists; Henry Francis Lyte and Charlotte Elliott among evangelicals in the Church of England; John Mason Neale and Christopher Wordsworth, bishop of Lincoln, among English churchmen of the higher school; Arthur Penrhyn Stanley, Edward H. Plumptre, Frances Ridley Havergal; and in Scotland, Dr Horatius Bonar, Dr Norman Macleod and Dr George Matheson. American hymn-writers belong to the same schools, and have been affected by the same influences. Some of them have

Heber, Milman, Keble.

Mant.

Newman.

enjoyed a just reputation on both sides of the Atlantic. Among those best known are John Greenleaf Whittier, Bishop Doane, Dr W. A. Muhlenberg and Thomas Hastings; and it is difficult to praise too highly such works as the Christmas hymn, "It came upon the midnight clear," by Edmund H. Sears; the Ascension hymn, "Thou, who didst stoop below," by Mrs S. E. Miles; two by Dr Ray Palmer, "My faith looks up to Thee, Thou Lamb of Calvary," and "Jesus, Thou joy of loving hearts," the latter of which is the best among several good English versions of "Jesu, dulcedo, cordium"; and "Lord of all being, throned afar," by Oliver Wendell Holmes.

The more modern "Moody and Sankey" hymns (see Moody, D. L.) popularized a new Evangelical type, and the Salvation Army has carried this still farther.

7. *Conclusion.*—The object aimed at in this article has been to trace the general history of the principal schools of ancient and modern hymnody, and especially the history of its use in the Christian church. For this purpose it has not been thought necessary to give any account of the hymns of Racine, Madame Guyon and others, who can hardly be classed with any school, nor of the works of Caesar Malan of Geneva (1787–1864) and other quite modern hymn-writers of the Reformed churches in Switzerland and France.

On a general view of the whole subject, hymnody is seen to have been a not inconsiderable factor in religious worship. It has been sometimes employed to disseminate and popularize particular views, but its spirit and influence has been, on the whole, catholic. It has embodied the faith, trust and hope, and no small part of the inward experience, of generation after generation of men, in many different countries and climates, of many different nations, and in many varieties of circumstances and condition. Coloured, indeed, by these differences, and also by the various modes in which the same truths have been apprehended by different minds and sometimes reflecting partial and imperfect conceptions of them, and errors with which they have been associated in particular churches, times and places, its testimony is, nevertheless, generally the same. It has upon it a stamp of genuineness which cannot be mistaken. It bears witness to the force of a central attraction more powerful than all causes of difference, which binds together times ancient and modern, nations of various race and language, churchmen and nonconformists, churches reformed and unreformed; to a true fundamental unity among good Christians; and to a substantial identity in their moral and spiritual experience. (S.)

The regular practice of hymnody in English musical history dates from the beginning of the 16th century. Luther's verses were adapted sometimes to ancient church melodies, sometimes to tunes of secular songs, and sometimes had music composed for them by himself and others. Many rhyming Latin hymns are of earlier date whose tunes are identified with them, some of which tunes, with the subject of their Latin text, are among the Reformer's appropriations; but it was he who put the words of praise and prayer into the popular mouth, associated with rhythmical music which aided to imprint the words upon the memory and to enforce their enunciation. In conjunction with his friend Johann Walther, Luther issued a collection of poems for choral singing in 1524, which was followed by many others in North Germany. The English versions of the Psalms by Sternhold and Hopkins and their predecessors, and the French version by Clement Marot and Theodore Beza, were written with the same purpose of fitting sacred minstrelsy to the voice of the multitude. Goudimel in 1566 and Claudin le Jeune in 1607 printed harmonizations of tunes that had then become standard for the Psalms, and in England several such publications appeared, culminating in Thomas Ravenscroft's famous collection, *The Whole Book of Psalms* (1621); in all of these the arrangements of the tunes were by various masters. The English practice of hymn-singing was much strengthened on the return of the exiled reformers from Frankfort and Geneva, when it became so general that, according to Bishop Jewell, thousands of the populace who assembled at Paul's Cross to hear the preaching would join in the singing of psalms before and after the sermon.

The placing of the choral song of the church within the lips of the people had great religious and moral influence; it has had also its great effect upon art, shown in the productions of the North German musicians ever since the first days of the Reformation, which abound in exercises of scholarship and imagination wrought upon the tunes of established acceptance. Some of these are accompaniments to the tunes with interludes between the several strains, and some are compositions for the organ or for orchestral instruments that consist of such elaboration of the themes as is displayed in accompaniments to voices, but of far more complicated and extended character. A special art-form that was developed to a very high degree, but has passed into comparative disuse, was the structure of all varieties of counterpoint extemporaneously upon the known hymn-tunes (chorals), and several masters acquired great fame by success in its practice, of whom J. A. Reinken (1623–1722), Johann Pachelbel (1653–1706), Georg Boehm and the great J. S. Bach are specially memorable. The hymnody of North Germany has for artistic treatment a strong advantage which is unpossessed by that of England, in that for the most part the same verses are associated with the same tunes, so that, whenever the text or the music is heard, either prompts recollection of the other, whereas in England tunes were always and are now often composed to metres and not to poems; any tune in a given metre is available for every poem in the same, and hence there are various tunes to one poem, and various poems to one tune.[1] In England a tune is named generally after some place—as "York," "Windsor," "Dundee,"—or by some other unsignifying word; in North Germany a tune is mostly named by the initial words of the verses to which it is allied, and consequently, whenever it is heard, whether with words or without, it necessarily suggests to the hearer the whole subject of that hymn of which it is the musical moiety undivorçeable from the literary half. Manifold as they are, knowledge of the choral tunes is included in the earliest schooling of every Lutheran and every Calvinist in Germany, which thus enables all to take part in performance of the tunes, and hence expressly the definition of "choral." Compositions grounded on the standard tune are then not merely school exercises, but works of art which link the sympathies of the writer and the listener, and aim at expressing the feeling prompted by the hymn under treatment.

HYPAETHROS (Gr. ὕπαιθρος, beneath the sky, in the open air, ὑπό, beneath, and αἰθήρ, air), the Greek term quoted by Vitruvius (iii. 2) for the opening in the middle of the roof of decastyle temples, of which "there was no example in Rome, but one in Athens in the temple of Jupiter Olympius, which is octastyle." But at the time he wrote (*c.* 25 B.C.) the cella of this temple was unroofed, because the columns which had been provided to carry, at all events, part of the ceiling and roof had been taken away by Sulla in 80 B.C. The decastyle temple of Apollo Didymaeus near Miletus was, according to Strabo (*c.* 50 B.C.), unroofed, on account of the vastness of its cella, in which precious groves of laurel bushes were planted. Apart from these two examples, the references in various writers to an opening of some kind in the roofs of temples dedicated to particular deities, and the statement of Vitruvius, which was doubtless based on the writings of Greek authors, that in decastyle or large temples the centre was open to the sky and without a roof (*medium autem sub divo est sine tecto*), render the existence of the hypaethros probable in some cases; and therefore C. R. Cockerell's discovery in the temple at Aegina of two fragments of a coping-stone, in which there were sinkings on one side to receive the tiles and covering tiles, has been of great importance in the discussion of this subject. In the conjectural restoration of the opaion or opening in the roof shown in Cockerell's drawing, it has been made needlessly large, having an area of about one quarter of the superficial area of the cella between the columns, and since in the Pantheon at Rome the relative proportions of the central opening in the dome and the area of the Rotunda are 1: 22, and the light there is ample, in the clearer atmosphere of Greece it might have been less. The larger the opening the more conspicuous would be the notch in the roof which is so greatly objected to; in this respect T. J. Hittorff would seem to be nearer the truth when, in his conjectural restoration of Temple R. at Selinus, he shows an opaion about half the relative size shown in Cockerell's of that at Aegina, the coping on the side elevation being much less noticeable. The problem was apparently solved in another way at Bassae, where, in the excavations of the temple of Apollo by Cockerell and Baron Haller von Hallerstein, three marble tiles were found with pierced openings in them about 18 in. by 10 in.; five of these pierced tiles on either side would have amply lighted the interior of the cella, and the amount of rain passing through (a serious element to be considered in a country where torrential rains occasionally fall) would not be very great or more than could be retained to dry up in the cella sunk pavement. In favour of both these methods of lighting the interior of the cella, the sarcophagus tomb at Cyrene, about 20 ft. long, carved in imitation of a temple, has been adduced, because, on the top of the roof and in its centre, there is a raised coping, and a similar feature is found on a tomb found near Delos; an example from Crete now in the British Museum shows a pierced tile on each side of the roof, and a large number of pierced tiles have been found in Pompeii, some of them surrounded with a rim identical with that of the marble tiles at Bassae. On the other hand, there are many authorities, among them Dr W. Dörpfeld, who have adhered to their original opinion that it was only through the open doorway that light was ever admitted into the cella, and with the clear atmosphere of Greece and the reflections from the marble pavement such lighting would be quite sufficient. There remains still another source of light to be considered, that passing through the Parian marble tiles of the roof; the superior translucency of Parian to any other marble may have suggested its employment for the roofs of temples, and if, in the framed ceilings carried over the cella, openings were left, some light from the Parian tile roof might have been obtained. It is possibly to this that Plutarch refers when describing the ceiling and roof of the temple of Demeter at Eleusis, where the columns in the interior of the temple carried a ceiling, probably constructed of timbers crossing one another at right angles, and one or more of the spaces was left open, which Xenocles surmounted by a roof formed of tiles.

James Fergusson put forward many years ago a conjectural restoration in which he adopted a clerestory above the superimposed columns inside the cella; in order to provide the light for these windows he indicated two trenches in the roof, one on each side, and pointed out that the great Hall of Columns at Karnak was lighted in this way with clerestory windows; but in the first place the light in the latter was obtained over the flat roofs covering lower portions of the hall, and in the second place, as it rarely rains in Thebes, there could be no difficulty about the drainage, while in Greece, with the torrential rains and snow, these trenches would be deluged with water, and with all the appliances of the present day it would be impossible to keep these clerestory windows watertight. There is, however, still another objection to Fergusson's theory; the water collecting in these trenches on the roof would have to be discharged, for which Fergusson's suggestions are quite inadequate, and the gargoyles shown in the cella wall would make the peristyle insupportable just at the time when it was required for shelter. No drainage otherwise of any kind has ever been found in any Greek temple, which is fatal to Fergusson's view. Nor is it in accordance with the definition "open to the sky." English cathedrals and churches are all lighted by clerestory windows, but no one has described them as open to the sky, and although Vitruvius's statements are sometimes confusing, his description is far too clear to leave any misunderstanding as to the lighting of temples (where it was necessary on account of great length) through an opening in the roof.

There is one other theory which has been put forward, but which can only apply to non-peristylar temples,—that light and air was admitted through the metopes, the apertures between the beams crossing the cella,—and it has been assumed that because Orestes was advised in one of the Greek plays to climb up and look through the metopes of the temple, these were left open; but if Orestes could look in, so could the birds, and the statue of the god would be defiled. The metopes were probably filled in with shutters of some kind which Orestes knew how to open. (R.P.S.)

HYPALLAGE (Gr. ὑπαλλαγή, interchange or exchange), a rhetorical figure, in which the proper relation between two words according to the rules of syntax are inverted. The stock instance is that in Virgil, *Aen.* iii. 61, where *dare classibus austros*, to give winds to the fleet, is put for *dare classes austris*, to give the fleet to the winds. The term is also loosely applied to figures of speech properly known as "metonymy" and, generally, to any striking turn of expression.

HYPATIA (Ὑπατία) (*c.* A.D. 370–415) mathematician and philosopher, born in Alexandria, was the daughter of Theon, also a mathematician and philosopher, author of scholia on Euclid and a commentary on the *Almagest*, in which it is suggested that he was assisted by Hypatia (on the 3rd book). After lecturing in her native city, Hypatia ultimately became the recognized head of the Neoplatonic school there (*c.* 400). Her great eloquence and rare modesty and beauty, combined with her remarkable intellectual gifts, attracted to her class-room a large number of pupils. Among these was Synesius, afterwards (*c.* 410) bishop of Ptolemaïs, several of whose letters to her, full of chivalrous admiration and reverence, are still extant. Suidas, misled by an incomplete excerpt in Photius from the life of Isidorus (the Neoplatonist) by Damascius, states that Hypatia was the wife of Isidorus; but this is chronologically impossible, since Isidorus could not have been born before 434 (see Hoche in *Philologus*). Shortly after the accession of Cyril to the patriarchate of Alexandria in 412, owing to her intimacy with Orestes, the pagan prefect of the city, Hypatia was barbarously murdered by the Nitrian monks and the fanatical Christian mob (March 415). Socrates has related how she was torn from her chariot, dragged to the Caesareum (then a Christian church), stripped naked, done to death with oyster-shells (ὀστράκοις ἀνεῖλον, perhaps "cut her throat") and finally burnt piecemeal. Most prominent among the actual perpetrators of the crime was one Peter, a reader; but there seems little reason to doubt Cyril's complicity (see CYRIL OF ALEXANDRIA).

Hypatia, according to Suidas, was the author of commentaries on the *Arithmetica* of Diophantus of Alexandria, on the *Conics* of Apollonius of Perga and on the astronomical canon (of Ptolemy). These works are lost; but their titles, combined with expressions in the letters of Synesius, who consulted her about the construction of an astrolabe and a hydroscope, indicate that she devoted herself specially to astronomy and mathematics. Little is known of her philosophical opinions, but she appears to have embraced the intellectual rather than the mystical side of Neoplatonism, and to have been a follower of Plotinus rather than of Porphyry and Iamblichus. Zeller, however, in his *Outlines of Greek Philosophy* (1886, Eng. trans. p. 347), states that "she appears to have taught the Neoplatonic doctrine in the form in which Iamblichus had stated it." A Latin letter to Cyril on behalf of Nestorius, printed in the *Collectio nova conciliorum*, i. (1623), by Stephanus Baluzius (Étienne Baluze, *q.v.*), and sometimes attributed to her, is undoubtedly spurious. The story of Hypatia appears in a considerably disguised yet still recognizable form in the legend of St Catherine as recorded in the Roman *Breviary* (November 25), and still more fully in the *Martyrologies* (see A.B. Jameson, *Sacred and Legendary Art* (1867) ii. 467.

The chief source for the little we know about Hypatia is the account given by Socrates (*Hist. ecclesiastica*, vii. 15). She is the subject of an epigram by Palladas in the Greek *Anthology* (ix. 400). See Fabricius, *Bibliotheca Graeca* (ed. Harles), ix. 187; John Toland, *Tetradymus* (1720); R. Hoche in *Philologus* (1860), xv. 435; monographs by Stephan Wolf (Czernowitz, 1879), H. Ligier (Dijon, 1880) and W. A. Meyer (Heidelberg, 1885), who devotes attention to the relation of Hypatia to the chief representatives of Neoplatonism; J. B. Bury, *Hist. of the Later Roman Empire* (1889), i. 208, 317; A. Güldenpenning, *Geschichte des oströmischen Reiches unter Arcadius und Theodosius II.* (Halle, 1885), p. 230; Wetzer and Welte, *Kirchenlexikon*, vi. (1889), from a Catholic standpoint. The story of Hypatia also forms the basis of the well-known historical romance by Charles Kingsley (1853).

HYPERBATON (Gr. ὑπέρβατον, a stepping over), the name of a figure of speech, consisting of a transposition of words from their natural order, such as the placing of the object before instead of after the verb. It is a common method of securing emphasis.

HYPERBOLA, a conic section, consisting of two open branches, each extending to infinity. It may be defined in several ways. The *in solido* definition as the section of a cone by a plane at a less inclination to the axis than the generator brings out the existence of the two infinite branches if we imagine the cone to be double and to extend to infinity. The *in plano* definition, *i.e.* as the conic having an eccentricity greater than unity, is a convenient starting-point for the Euclidian investigation. In projective geometry it may be defined as the conic which intersects the line at infinity in two real points, or to which it is possible to draw two real tangents from the centre. Analytically, it is defined by an equation of the second degree, of which the highest terms have real roots (see CONIC SECTION).

While resembling the parabola in extending to infinity, the curve has closest affinities to the ellipse. Thus it has a real centre, two foci, two directrices and two vertices; the transverse axis, joining the vertices, corresponds to the major axis of the ellipse, and the line through the centre and perpendicular to this axis is called the conjugate axis, and corresponds to the minor axis of the ellipse; about these axes the curve is symmetrical. The curve does not appear to intersect the conjugate axis, but the introduction of imaginaries permits us to regard it as cutting this axis in two unreal points. Calling the foci S, S′, the real vertices A, A′, the extremities of the conjugate axis B, B′ and the centre C, the positions of B, B′ are given by AB = AB′ = CS. If a rectangle be constructed about AA′ and BB′, the diagonals of this figure are the "asymptotes" of the curve; they are the tangents from the centre, and hence touch the curve at infinity. These two lines may be pictured in the *in solido* definition as the section of a cone by a plane through its vertex and parallel to the plane generating the hyperbola. If the asymptotes be perpendicular, or, in other words, the principal axes be equal, the curve is called the rectangular hyperbola. The hyperbola which has for its transverse and conjugate axes the transverse and conjugate axes of another hyperbola is said to be the conjugate hyperbola.

Some properties of the curve will be briefly stated: If PN be the ordinate of the point P on the curve, AA′ the vertices, X the meet of the directrix and axis and C the centre, then $PN^2 : AN.NA' :: SX^2 : AX.A'X$, *i.e.* PN^2 is to AN.NA′ in a constant ratio. The circle on AA′ as diameter is called the auxiliarly circle; obviously AN.NA′ equals the square of the tangent to this circle from N, and hence the ratio of PN to the tangent to the auxiliarly circle from N equals the ratio of the conjugate axis to the transverse. We may observe that the asymptotes intersect this circle in the same points as the directrices. An important property is: the difference of the focal distances of any point on the curve equals the transverse axis. The tangent at any point bisects the angle between the focal distances of the point, and the normal is equally inclined to the focal distances. Also the auxiliarly circle is the locus of the feet of the perpendiculars from the foci on any tangent. Two tangents from any point are equally inclined to the focal distance of the point. If the tangent at P meet the conjugate axis in t, and the transverse in N, then $Ct.\,PN = BC^2$; similarly if g and G be the corresponding intersections of the normal, $PG : Pg :: BC^2 : AC^2$. A diameter is a line through the centre and terminated by the curve: it bisects all chords parallel to the tangents at its extremities; the diameter parallel to these chords is its conjugate diameter. Any diameter is a mean proportional between the transverse axis and the focal chord parallel to the diameter. Any line cuts off equal distances between the curve and the asymptotes. If the tangent at P meets the asymptotes in R, R′, then $CR.CR' = CS^2$. The geometry of the rectangular hyperbola is simplified by the fact that its principal axes are equal.

Analytically the hyperbola is given by $ax^2+2hxy+by^2+2gx+2fy+c=0$ wherein $ab>h^2$. Referred to the centre this becomes $Ax^2+2Hxy+By^2+C=0$; and if the axes of coordinates be the principal axes of the curve, the equation is further simplified to $Ax^2-By^2=C$, or if the semi-transverse axis be a, and the semi-conjugate b, $x^2/a^2-y^2/b^2=1$. This is the most commonly used form. In the rectangular hyperbola $a=b$; hence its equation is $x^2-y^2=0$. The equations to the asymptotes are $x/a=\pm y/b$ and $x=\pm y$ respectively. Referred to the asymptotes as axes the general equation becomes $xy=k^2$; obviously the axes are oblique in the general hyperbola and rectangular in the rectangular hyperbola. The values of the constant k^2 are $\frac{1}{2}(a^2+b^2)$ and $\frac{1}{2}a^2$ respectively. (See GEOMETRY: *Analytical*; *Projective*.)

HYPERBOLE (from Gr. ὑπερβάλλειν, to throw beyond), a figure of rhetoric whereby the speaker expresses more than the truth, in order to produce a vivid impression; hence, an exaggeration.

HYPERBOREANS (Ὑπερβόρεοι, Ὑπερβόρειοι), a mythical people intimately connected with the worship of Apollo. Their name does not occur in the *Iliad* or the *Odyssey*, but Herodotus (iv. 32) states that they were mentioned in Hesiod and in the *Epigoni*, an epic of the Theban cycle. According to Herodotus, two maidens, Opis and Arge, and later two others, Hyperoche and Laodice, escorted by five men, called by the Delians Perpherеës, were sent by the Hyperboreans with certain offerings to Delos. Finding that their messengers did not return, the Hyperboreans adopted the plan of wrapping the offerings in wheat-straw and requested their neighbours to hand them on to the next nation, and so on, till they finally reached Delos. The theory of H. L. Ahrens, that Hyperboreans and Perpherеës are identical, is now widely accepted. In some of the dialects of northern Greece (especially Macedonia and Delphi) φ had a tendency to become β. The original form of Περφερέες was ὑπερφερέται or ὑπέρφοροι ("those who carry over"), which becoming ὑπέρβοροι gave rise to the popular derivation from βορέας ("dwellers beyond the north wind"). The Hyperboreans were thus the bearers of the sacrificial gifts to Apollo over land and sea, irrespective of their home, the name being given to Delphians, Thessalians, Athenians and Delians. It is objected by O. Schröder that the form Περφερέες requires a passive meaning, "those who are carried round the altar," perhaps dancers like the whirling dervishes; distinguishing them from the Hyperboreans, he explains the latter as those who live "above the mountains," that is, in heaven. Under the influence of the derivation from *βορέας*, the home of the Hyperboreans was placed in a region beyond the north wind, a paradise like the Elysian plains, inaccessible by land or sea, whither Apollo could remove those mortals who had lived a life of piety. It was a land of perpetual sunshine and great fertility; its inhabitants were free from disease and war. The duration of their life was 1000 years, but if any desired to shorten it, he decked himself with garlands and threw himself from a rock into the sea. The close connexion of the Hyperboreans with the cult of Apollo may be seen by comparing the Hyperborean myths, the characters of which by their names mostly recall Apollo or Artemis (Agyieus, Opis, Hecaergos, Loxo), with the ceremonial of the Apolline worship. No meat was eaten at the Pyanepsia; the Hyperboreans were vegetarians. At the festival of Apollo at Leucas a victim flung himself from a rock into the sea, like the Hyperborean who was tired of life. According to an Athenian decree (380 B.C.) asses were sacrificed to Apollo at Delphi, and Pindar (*Pythia*, x. 33) speaks of " hecatombs of asses " being offered to him by the Hyperboreans. As the latter conveyed sacrificial gifts to Delos hidden in wheat-straw, so at the Thargelia a sheaf of corn was carried round in procession, concealing a symbol of the god (for other resemblances see Crusius's article). Although the Hyperborean legends are mainly connected with Delphi and Delos, traces of them are found in Argos (the stories of Heracles, Perseus, Io), Attica, Macedonia, Thrace, Sicily and Italy (which Niebuhr indeed considers their original home). In modern times the name has been applied to a group of races, which includes the Chukchis, Koryaks, Yukaghirs, Ainus, Gilyaks and Kamchadales, inhabiting the arctic regions of Asia and America. But if ever ethnically one, the Asiatic and American branches are now as far apart from each other as they both are from the Mongolo-Tatar stock.

See O. Crusius in Roscher's *Lexikon der Mythologie*; O. Schröder in *Archiv für Religionswissenschaft* (1904), viii. 69; W. Mannhardt, *Wald- und Feldkulte* (1905); L. R. Farnell, *Cults of the Greek States* (1907), iv. 100.

HYPEREIDES (*c.* 390–322 B.C.), one of the ten Attic orators, was the son of Glaucippus, of the deme of Collytus. Having studied under Isocrates, he began life as a writer of speeches for the courts, and in 360 he prosecuted Autocles, a general charged with treason in Thrace (frags. 55-65, Blass). At the time of the so-called " Social War " (358–355) he accused Aristophon, then one of the most influential men at Athens, of malpractices (frags. 40-44, Blass), and impeached Philocrates (343) for high treason. From the peace of 346 to 324 Hypereides supported Demosthenes in the struggle against Macedon; but in the affair of Harpalus he was one of the ten public prosecutors of Demosthenes, and on the exile of his former leader he became the head of the patriotic party (324). After the death of Alexander, he was the chief promoter of the Lamian war against Antipater and Craterus. After the decisive defeat at Crannon (322), Hypereides and the other orators, whose surrender was demanded by Antipater, were condemned to death by the Athenian partisans of Macedonia. Hypereides fled to Aegina, but Antipater's emissaries dragged him from the temple of Aeacus, where he had taken refuge, and put him to death; according to others, he was taken before Antipater at Athens or Cleonae. His body was afterwards removed to Athens for burial.

Hypereides was an ardent pursuer of " the beautiful," which in his time generally meant pleasure and luxury. His temper was easy-going and humorous; and hence, though in his development of the periodic sentence he followed Isocrates, the essential tendencies of his style are those of Lysias, whom he surpassed, however, in the richness of his vocabulary and in the variety of his powers. His diction was plain and forcible, though he occasionally indulged in long compound words probably borrowed from the Middle Comedy, with which, and with the everyday life of his time, he was in full sympathy. His composition was simple. He was specially distinguished for subtlety of expression, grace and wit, as well as for tact in approaching his case and handling his subject matter. Sir R. C. Jebb sums up the criticism of pseudo-Longinus (*De sublimitate*, 34) in the phrase—" Hypereides was the Sheridan of Athens."

Seventy-seven speeches were attributed to Hypereides, of which twenty-five were regarded as spurious even by ancient critics. It is said that a MS. of most of the speeches was in existence in the 16th century in the library of Matthias Corvinus, king of Hungary, at Ofen, but was destroyed at the capture of the city by the Turks in 1526. Only a few fragments were known until comparatively recent times. In 1847 large fragments of his speeches *Against Demosthenes* (see above) and *For Lycophron* (incidentally interesting as elucidating the order of marriage processions and other details of Athenian life, and the Athenian government of Lemnos), and the whole of the *For Euxenippus* (*c.* 330, a *locus classicus* on εἰσαγγελίαι or state prosecutions), were found in a tomb at Thebes in Egypt, and in 1856 a considerable portion of a λόγος ἐπιτάφιος, a *Funeral Oration* over Leosthenes and his comrades who had fallen in the Lamian war, the best extant specimen of epideictic oratory (see BABINGTON, CHURCHILL). Towards the end of the century further discoveries were made of the conclusion of the speech *Against Philippides* (dealing with a γραφὴ παρανόμων, or indictment for the proposal of an unconstitutional measure, arising out of the disputes of the Macedonian and anti-Macedonian parties at Athens), and of the whole of the *Against Athenogenes* (a perfumer accused of fraud in the sale of his business). These have been edited by F. G. Kenyon (1893). An important speech that is lost is the *Deliacus* (frags. 67-75, Blass) on the presidency of the Delian temple claimed by both Athens and Delos, which was adjudged by the Amphictyons to Athens.

On Hypereides generally see pseudo-Plutarch, *Decem oratorum vitae*; F. Blass, *Attische Beredsamkeit*, iii.; R. C. Jebb, *Attic Orators*, ii. 381. A full list of editions and articles is given in F. Blass, *Hyperidis orationes sex cum ceterarum fragmentis* (1894, Teubner series), to which may be added I. Bassi, *Le Quattro Orazioni di Iperide* (introduction and notes, 1888), and J. E. Sandys in *Classical Review* (January 1895) (a review of the editions of Kenyon and Blass). For the discourse against Athenogenes see H. Weil, *Études sur l'antiquité grecque* (1900).

HYPERION, in Greek mythology, one of the Titans, son of Uranus and Gaea and father of Helios, the sun-god (Hesiod, *Theog.* 134, 371; Apollodorus i. 1. 2). In the well-known passage in Shakespeare (*Hamlet*, i. 2: " Hyperion to a satyr," where as in other poets the vowel *-i-* though really long, is shortened for metrical reasons) Hyperion is used for Apollo as expressive of the idea of beauty. The name is often used as an epithet of Helios, who is himself sometimes called simply Hyperion. It is explained as (1) he who moves above (ὑπερ-ιων), but the quantity of the vowel is against this; (2) he who is above (ὑπερι-ων). Others take it to be a patronymic in form, like Κρονῖων, Μολῖων.

HYPERSTHENE, a rock-forming mineral belonging to the group of orthorhombic pyroxenes. It differs from the other members (enstatite [*q.v.*] and bronzite) of this group in containing a considerable amount of iron replacing magnesium: the chemical formula is $(Mg,Fe)SiO_3$. Distinctly developed crystals are rare, the mineral being usually found as foliated masses embedded in those igneous rocks—norite, hypersthene-andesite, &c.—of which it forms an essential constituent. The coarsely grained labradorite-hypersthene-rock (norite) of the island of St Paul off the coast of Labrador has furnished the most typical material; and for this reason the mineral has been known as " Labrador hornblende " or paulite. The colour is brownish-black, and the pleochrism strong; the hardness is 6, and the specific gravity 3·4-3·5. On certain surfaces it displays a brilliant copper-red metallic sheen or schiller, which has the same origin as the bronzy sheen of bronzite (*q.v.*), but is even more pronounced. Like bronzite, it is sometimes cut and polished for ornamental purposes. (L. J. S.)

HYPERTROPHY (Gr. ὑπέρ, over, and τροφή, nourishment), a term in medicine employed to designate an abnormal increase in bulk of one or more of the organs or component tissues of the body (see PATHOLOGY). In its strict sense this term can only be applied where the increase affects the natural textures of a part, and is not applicable where the enlargement is due to the presence of some extraneous morbid formation. Hypertrophy of a part may manifest itself either by simply an increase in the size of its constituents, or by this combined with an increase in their number (hyperplasia). In many instances both are associated.

The conditions giving rise to hypertrophy are the reverse of those described as producing ATROPHY (*q.v.*). They are concisely stated by Sir James Paget as being chiefly or only three, namely: (1) the increased exercise of a part in its healthy functions; (2) an increased accumulation in the blood of the particular materials which a part appropriates to its nutrition or in secretion; and (3) an increased afflux of healthy blood.

Illustrations are furnished of the first of these conditions by the high development of muscular tissue under habitual active exercise; of the second in the case of obesity, which is an hypertrophy of the fatty tissues, the elements of which are furnished by the blood; and of the third in the occasional overgrowth of hair in the neighbourhood of parts which are the seat of inflammation. Obviously therefore, in many instances, hypertrophy cannot be regarded as a deviation from health, but rather on the contrary as indicative of a high degree of nutrition and physical power. Even in those cases where it is found associated with disease, it is often produced as a salutary effort of nature to compensate for obstructions or other difficulties which have arisen in the system, and thus to ward off evil consequences. No better example of this can be seen than in the case of certain forms of heart disease, where from defect at some of the natural orifices of that organ the onward flow of the blood is interfered with, and would soon give rise to serious embarrassment to the circulation, were it not that behind the seat of obstruction the heart gradually becomes hypertrophied, and thus acquires greater propelling power to overcome the resistance in front. Again, it has been noticed, in the case of certain double organs such as the kidneys, that when one has been destroyed by disease the other has become hypertrophied to such a degree as enables it to discharge the functions of both.

Hypertrophy may, however, in certain circumstances constitute a disease, as in goitre and elephantiasis (*q.v.*), and also in the case of certain tumours and growths (such as cutaneous excrescences, fatty tumours, mucous polypi, &c.), which are simply enlargements of normal textures. Hypertrophy does not in all cases involve an increase in bulk; for, just as in atrophy there may be no diminution in the size of the affected organ, so in hypertrophy there may be no increase. This is apt to be the case where certain only of the elements of an organ undergo increase, while the others remain unaffected or are actually atrophied by the pressure of the hypertrophied tissue, as is seen in the disease known as cirrhosis of the liver.

A spurious hypertrophy is observed in the rare disease to which G. B. Duchenne applied the name of *pseudo-hypertrophic paralysis*. This ailment, which appears to be confined to children, consists essentially of a progressive loss of power accompanied with a remarkable enlargement of certain muscles or groups of muscles, more rarely of the whole muscular system. This increase of bulk is, however, not a true hypertrophy, but rather an excessive development of connective tissue in the substance of the muscles, the proper texture of which tends in consequence to undergo atrophy or degeneration. The appearance presented by a child suffering from this disease is striking. The attitude and gait are remarkably altered, the child standing with shoulders thrown back, small of the back deeply curved inwards, and legs wide apart, while walking is accompanied with a peculiar swinging or rocking movement. The calves of the legs, the buttocks, the muscles of the back, and occasionally other muscles, are seen to be unduly enlarged, and contrast strangely with the general feebleness. The progress of the disease is marked by increasing failure of locomotory power, and ultimately by complete paralysis of the limbs. The malady is little amenable to treatment, and, although often prolonged for years, generally proves fatal before the period of maturity.

HYPNOTISM, a term now in general use as covering all that pertains to the art of inducing the hypnotic state, or hypnosis, and to the study of that state, its conditions, peculiarities and effects. Hypnosis is a condition, allied to normal sleep (Gr. **ὕπνος**), which can be induced in a large majority of normal persons. Its most characteristic and constant symptom is the increased suggestibility of the subject (see SUGGESTION). Other symptoms are very varied and differ widely in different subjects and in the same subject at different times. There can be no doubt that the increased suggestibility and all the other symptoms of hypnosis imply some abnormal condition of the brain of a temporary and harmless nature. It would seem that in all ages and in almost all countries individuals have occasionally fallen into abnormal states of mind more or less closely resembling the hypnotic state, and have thereby excited the superstitious wonder of their fellows. In some cases the state has been deliberately induced, in others it has appeared spontaneously, generally under the influence of some emotional excitement. The most familiar of these allied states is the somnambulism or sleep-walking to which some persons seem to be hereditarily disposed. Of a rather different type are the states of ecstasy into which religious enthusiasts have occasionally fallen and which were especially frequent among the peoples of Europe during the middle ages. While in this condition individuals have appeared to be insensitive to all impressions made on their sense-organs, even to such as would excite acute pain in normal persons, have been capable of maintaining rigid postures for long periods of time, have experienced vivid hallucinations, and have produced, through the power of the imagination, extraordinary organic changes in the body, such as the bloody stigmata on the hands and feet in several well-attested instances. It has been proved in recent years that effects of all these kinds may be produced by hypnotic suggestion. Different again, but closely paralleled by some subjects in hypnosis, is the state of *latah* into which a certain proportion of persons of the Malay race are liable to fall. These persons, if their attention is suddenly and forcibly drawn to any other person, will begin to imitate his every action and attitude, and may do so in spite of their best efforts to restrain their imitative movements. Among the half-bred French-Canadians of the forest regions of Canada occur individuals, known as "jumpers," who are liable to fall suddenly into a similar state of abject imitativeness, and the same peculiar behaviour has been observed among some of the remote tribes of Siberia.

The deliberate induction of states identical with, or closely allied to, hypnosis is practised by many barbarous and savage peoples, generally for ceremonial purposes. Thus, certain dervishes of Algiers are said to induce in themselves, by the aid of the sound of drums, monotonous songs and movements, a state in which they are insensitive to pain, and a similar practice of religious devotees is reported from Tibet. Perhaps the most marvellous achievement among well-attested cases of this sort is that of certain *yogis* of Hindustan; by long training and practice they seem to acquire the power of arresting almost completely all their vital functions. An intense effort of abstraction from the impressions of the outer world, a prolonged fixation of the eyes upon the nose or in some other strained position and a power of greatly slowing the respiration, these seem to be important features of their procedure for the attainment of their abnormal states.

In spite of the wide distribution in time and space, and the not very infrequent occurrence, of these instances of states identical with or allied to hypnosis, some three centuries of enthusiastic investigation and of bitter controversy were required to establish the occurrence of the hypnotic state among the facts accepted by the world of European science. Scientific interest in them may be traced back at least as far as the end of the 16th century. Paracelsus had founded the "sympathetic system" of medicine, according to which the stars and other bodies, especially magnets, influence men by means of a subtle emanation or fluid that pervades all space. J. B. van Helmont, a distinguished man of science of the latter part of the 16th century, extended this doctrine by teaching that a similar magnetic fluid radiates from men, and that it can be guided by their wills to influence directly the minds and bodies of others. In the middle of the 17th century there appeared in England several persons who claimed to have the power of curing diseases by stroking with the hand. Notable amongst these was Valentine Greatrakes, of Affane, in the county of Waterford, Ireland, who was born in

February 1628, and who attracted great attention in England by his supposed power of curing the king's evil, or scrofula. Many of the most distinguished scientific and theological men of the day, such as Robert Boyle and R. Cudworth, witnessed and attested the cures supposed to be effected by Greatrakes, and thousands of sufferers crowded to him from all parts of the kingdom. About the middle of the 18th century John Joseph Gassner, a Roman Catholic priest in Swabia, took up the notion that the majority of diseases arose from demoniacal possession, and could only be cured by exorcism. His method was undoubtedly similar to that afterwards followed by Mesmer and others, and he had an extraordinary influence over the nervous systems of his patients. Gassner, however, believed his power to be altogether supernatural.

But it was not until the latter part of the 18th century that the doctrine of a magnetic fluid excited great popular interest and became the subject of fierce controversy in the scientific world. F. A. Mesmer (*q.v.*), a physician of Vienna, was largely instrumental in bringing the doctrine into prominence. He developed it by postulating a specialized variety of magnetic fluid which he called *animal magnetism*; and he claimed to be able to cure many diseases by means of this animal magnetism, teaching, also, that it may be imparted to and stored up in inert objects, which are thereby rendered potent to cure disease.

It would seem that Mesmer himself was not acquainted with the artificial somnambulism which for nearly a century was called mesmeric or magnetic sleep, and which is now familiar as hypnosis of a well-marked degree. It was observed and described about the year 1780 by the marquis de Puységur, a disciple of Mesmer, who showed that, while subjects were in this state, not only could some of their diseases be cured, but also their movements could be controlled by the "magnetizer," and that they usually remembered nothing of the events of the period of sleep when restored to normal consciousness. These are three of the most important features of hypnosis, and the modern study of hypnotism may therefore be said to have been initiated at this date by Puységur. For, though it is probable that this state had often been induced by the earlier magnetists, they had not recognized that the peculiar behaviour of their patients resulted from their being plunged into this artificial sleep, but had attributed all the symptoms they observed to the direct physical action of external agents upon the patients.

The success of Mesmer and his disciples, especially great in the fashionable world, led to the appointment in Paris of a royal commission for the investigation of their claims. The commission, which included men of great eminence, notably A. L. Lavoisier and Benjamin Franklin, reported in the year 1784 that it could not accept the evidence for the existence of the magnetic fluid; but it did not express an opinion as to the reality of the cures said to be effected by its means, nor as to the nature of the magnetic sleep. This report and the social upheavals of the following years seem to have abolished the public interest in "animal magnetism" for the space of one generation; after which Alexandre Bertrand, a Parisian physician, revived it by his acute investigations and interpretations of the phenomena. Bertrand was the first to give an explanation of the facts of the kind that is now generally accepted. He exhibited the affinity of the "magnetic sleep" to ordinary somnambulism, and he taught that the peculiar effects are to be regarded as due to the suggestions of the operator working themselves out in the mind and body of the "magnetized" subject, *i.e.* he regarded the influence of the magnetizer as exerted in the first instance on the mind of the subject and only indirectly through the mind upon the body. Shortly after this revival of public interest, namely in the year 1831, a committee of the Academy of Medicine of Paris reported favourably upon "magnetism" as a therapeutic agency, and before many years had elapsed it was extensively practised by the physicians of all European countries, with few exceptions, of which England was the most notable. Most of the practitioners of this period adhered to the doctrine of the magnetic fluid emanating from the operator to his patient, and the acceptance of this doctrine was commonly combined with belief in phrenology, astrology and the influence of metals and magnets, externally applied, in curing disease and in producing a variety of strange sensations and other affections of the mind. These beliefs, claiming to rest upon carefully observed facts, were given a new elaboration and a more imposing claim to be scientifically established by the doctrine of *odylic force* propounded by Baron Karl von Reichenbach. In this mass of ill-based assertion and belief the valuable truths of "animal magnetism" and the psychological explanations of them given by Bertrand were swamped and well-nigh lost sight of. For it was this seemingly inseparable association between the facts of hypnotism and these bizarre practices and baseless beliefs that blinded the larger and more sober part of the scientific world, and led them persistently to assert that all this group of alleged phenomena was a mass of quackery, fraud and superstition. And the fact that magnetism was practised for pecuniary gain, often in a shameless manner, by exponents who claimed to cure by its means every conceivable ill, rendered this attitude on the part of the medical profession inevitable and perhaps excusable, though not justifiable. It was owing to this baleful association that John Elliotson, one of the leading London physicians of that time, who became an ardent advocate of "magnetism" and who founded and edited the *Zoist* in the interests of the subject, was driven out of the profession. This association may perhaps be held, also, to excuse the hostile attitude of the medical profession towards James Esdaile, a surgeon, who, practising in a government hospital in Calcutta among the natives of India, performed many major operations, such as the amputation of limbs, painlessly and with the most excellent results by aid of the "magnetic" sleep. For both Elliotson and Esdaile, though honourable practitioners, accepted the doctrine of the "magnetic" fluid and many of the erroneous beliefs that commonly were bound up with it.

In 1841 James Braid, a surgeon of Manchester, rediscovered independently Bertrand's physiological and psychological explanations of the facts, carried them further, and placed "hypnotism," as he named the study, on a sound basis. Braid showed that subjects in "magnetic" sleep, far from being in a profoundly insensitive condition, are often abnormally susceptible to impressions on the senses, and showed that many of the peculiarities of their behaviour were due to suggestions, made verbally or otherwise, but unintentionally, by the operator or by onlookers.

It seems, on looking back on the history of hypnotism, that at this time it was in a fair way to secure general recognition as a most interesting subject of psychological study and a valuable addition to the resources of the physician. But it was destined once more to be denied its rights by official science and to fall back into disrepute. This was due to the coincidence about the year 1848 of two events of some importance, namely—the discovery of the anaesthetic properties of chloroform and the sudden rise of modern spiritualism. The former afforded a very convenient substitute for the most obvious practical application of hypnotism, the production of anaesthesia during surgical operations; the latter involved it once more in a mass of fraud and superstition, and, for the popular mind, drove it back to the region of the marvellous, the supernatural and the dangerous, made it, in fact, once more a branch of the black art.

From this time onward there took place a gradual differentiation of the "animal magnetism" of the 18th century into two diverging branches, hypnotism and spiritualism, two branches which, however, are not yet entirely separated and, perhaps, never will be. At the same time the original system of "animal magnetism" has lived on in an enfeebled condition and is now very nearly, though not quite, extinct.

In the development of hypnotism since the time of Braid we may distinguish three lines, the physiological, the psychological and the pathological. The last may be dismissed in a few words. Its principal representative was J. M. Charcot, who taught at the Salpêtrière in Paris that hypnosis is essentially a symptom of a morbid condition of hysteria or hystero-epilepsy. This doctrine, which, owing to the great repute enjoyed by Charcot, has done much to retard the application of hypnotism, is now completely discredited. The workers of the physiological party attached special importance to the fixation of the eyes, or to other forms of long continued and monotonous, or violent, sensory stimulation in the induction of hypnosis. They believed that by acting on the senses in these ways they induced a peculiar condition of the nervous system, which consisted in the temporary abolition of the cerebral functions and the consequent reduction of the subject to machine-like unconscious automatism. The leading exponent of this view was R. Heidenhain, professor of physiology at Breslau, whose experimental investigations played a large part in convincing the scientific world of the genuineness of the leading symptoms of hypnosis. The purely psychological doctrine of hypnosis puts aside all physical and physiological influences and effects as of but little or no importance, and seeks a psychological explanation of the induction of hypnosis and of all the phenomena. This dates from 1884, when H. Bernheim, professor of medicine at Nancy, published his work *De la Suggestion* (republished in 1887 with a second part on the therapeutics of hypnotism). Bernheim was led to the study of hypnotism by A. A. Liébeault, who for twenty years had used it very largely and successfully in his general practice among the poor of Nancy. Liébeault rediscovered independently, and Bernheim made known to the world the truths, twice previously discovered and twice lost sight of, that expectation is a most important factor in the induction of hypnosis, that increased suggestibility is its essential symptom, and that in general the operator works upon his patient by mental influences. Although they went too far in the direction of ignoring the peculiarity of the state of the brain in hypnosis and the predisposing effect of monotonous sensory stimulation, and in seeking to identify hypnosis with normal sleep, the views of the Nancy investigators have prevailed, and are now in the main generally accepted. Their methods of verbal suggestion have been adopted by leading physicians in almost all civilized countries and have been proved to be efficacious in the relief of many disorders; and as a method of psychological investigation hypnotism has proved, especially in the hands of the late Ed. Gurney, of Dr Pierre Janet and of other investigators, capable of throwing much light on the constitution of the mind, has opened up a number of problems of the deepest interest, and has done more than any other of the many branches of modern psychology to show the limitations and comparative barrenness of the old psychology that relied on introspection alone and figured as a department of general philosophy. In England, " always the last to enter into the general movement of the European mind," the prejudice, incredulity and ignorant misrepresentation with which hypnotism has everywhere been received have resisted its progress more stubbornly than elsewhere; but even in England its reality and its value as a therapeutic agent have at last been officially recognized. In 1892, just fifty years after Braid clearly demonstrated the facts and published explanations of them almost identical with those now accepted, a committee of the British Medical Association reported favourably upon hypnotism after a searching investigation; it is now regularly employed by a number of physicians of high standing, and the formation in 1907 of " The Medical Society for the Study of Suggestive Therapeutics " shows that the footing it has gained is likely to be made good.

Induction of Hypnosis.—It has now been abundantly proved that hypnosis can be induced in the great majority of normal persons, provided that they willingly submit themselves to the process. Several of the most experienced operators have succeeded in hypnotizing more than 90% of the cases they have attempted, and most of them are agreed that failure to induce hypnosis in any case is due either to lack of skill and tact on the part of the operator, or to some unfavourable mental condition of the subject. It has often been said that some races or peoples are by nature more readily hypnotizable than others; of the French people especially this has been maintained. But there is no sufficient ground for this statement. The differences that undoubtedly obtain between populations of different regions in respect to the ease or difficulty with which a large proportion of all persons can be hypnotized are sufficiently explained by the differences of the attitude of the public towards hypnotism; in France, *e.g.*, and especially in Nancy, hypnotism has been made known to the public chiefly as a recognized auxiliary to the better known methods of medical treatment, whereas in England the medical profession has allowed the public to make acquaintance with hypnotism through the medium of disgusting stage-performances whose only object was to raise a laugh, and has, with few exceptions, joined in the general chorus of condemnation and mistrust. Hence in France patients submit themselves with confidence and goodwill to hypnotic treatment, whereas in England it is still necessary in most cases to remove an ill-based prejudice before the treatment can be undertaken with hope of success. For the confidence and goodwill of the patient are almost essential to success, and even after hypnosis has been induced on several occasions a patient may be so influenced by injudicious friends that he cannot again be hypnotized or, if hypnotized, is much less amenable to the power of suggestion. Various methods of hypnotization are current, but most practitioners combine the methods of Braid and of Bernheim. After asking the patient to resign himself passively into their hands, and after seating him in a comfortable arm-chair, they direct him to fix his eyes upon some small object held generally in such a position that some slight muscular strain is involved in maintaining the fixation; they then suggest to him verbally the idea or expectation of sleep and the sensations that normally accompany the oncoming of sleep, the heaviness of the eyes, the slackness of the limbs and so forth; and when the eyes show signs of fatigue, they either close them by gentle pressure or tell the subject to close them. Many also pass their hands slowly and regularly over the face, with or without contact. The old magnetizers attached great importance to such " passes," believing that by them the " magnetic fluid " was imparted to the patient; but it seems clear that, in so far as they contribute to induce hypnosis, it is in their character merely of gentle, monotonous, sensory stimulations. A well-disposed subject soon falls into a drowsy state and tends to pass into natural sleep; but by speech, by passes, or by manipulating his limbs the operator keeps in touch with him, keeps his waning attention open to the impressions he himself makes. Most subjects then find it difficult or impossible to open their eyes or to make any other movement which is forbidden or said to be impossible by the operator, although they may be fully conscious of all that goes on about them and may have the conviction that if they did but make an effort they could break the spell. This is a light stage of hypnosis beyond which some subjects can hardly be induced to pass and beyond which few pass at the first attempt. But on successive occasions, or even on the first occasion, a favourable subject passes into deeper stages of hypnosis. Many attempts have been made to distinguish clearly marked and constantly occurring stages. But it seems now clear that the complex of symptoms displayed varies in all cases with the idiosyncrasies of the subject and with the methods adopted by the operator. In many subjects a waxy rigidity of the limbs appears spontaneously or can be induced by suggestion; the limbs then retain for long periods without fatigue any position given them by the operator. The most susceptible subjects pass into the stage known as artificial somnambulism. In this condition they continue to respond to all suggestions made by the operator, but seem as insensitive to all other impressions as a person in profound sleep or in coma; and on awaking from this condition they are usually oblivious of all that they have heard, said or done during the somnambulistic period. When in this last condition patients are usually more profoundly influenced by suggestions, especially post-hypnotic suggestions, than when in the lighter stages; but the lighter stages suffice for the production of many therapeutic effects. When a patient is completely hypnotized, his movements, his senses, his ideas and, to some extent, even the organic processes over which he has no voluntary control become more or less completely subject to the suggestions of the operator; and usually he is responsive to the operator alone (*rapport*) unless he is instructed by the latter to respond also to the suggestions of other persons. If left to himself the hypnotized subject will usually awake to his normal state after a period which is longer in proportion to the depth of hypnosis; and the deeper stages seem to pass over into normal sleep. The subject can in almost every case be brought quickly back to the normal state by the verbal command of the operator.

The Principal Effects produced by Suggestion during Hypnosis.—The subject may not only be rendered incapable of contracting any of the muscles of the voluntary system, but may also be made to use them with extraordinarily great or sustained force (though by no means in all cases). He can with difficulty refrain from performing any action commanded by the operator, and usually carries out any simple command without hesitation. Any one of the sense-organs, or any sensory region such as the skin or deep tissues of one limb may be rendered anaesthetic by verbal suggestion, aided perhaps by some gentle manipulation of the part. On this fact depends the surgical application of hypnotism. Sceptical observers are always inclined to doubt the genuineness of the anaesthesia produced by a mere word of command, but the number of surgical operations performed under hypnotic anaesthesia suffices to put its reality beyond all question. A convincing experiment may, however, be made on almost any good subject. Anaesthesia of one eye may be suggested and its reality tested in the following way. Anaesthesia of the left eye may be suggested, and the subject be instructed to fix his gaze on a distant point and to give some signal as soon as he sees the operator's finger in the peripheral field of view. The operator then brings his finger slowly from behind and to the right forwards towards the subject's line of sight. The subject signals as soon as it crosses the normal temporal boundary of the field of view of the right eye. The operator then brings his finger forward from a point behind and to the left of the subject's head. The subject allows it to cross the monocular field of the left eye and signals only when the finger enters the field of vision of the right eye across its nasal boundary. Since few persons, other than physiologists or medical men, are aware of the relations of the boundaries of the monocular and binocular fields of vision, the success of this experiment affords proof that the finger remains invisible to the subject during its passage across the monocular field of the left eye. The abolition of pain, especially of neuralgias, the pain of rheumatic and other inflammations, which is one of the most valuable applications of hypnotism, is an effect closely allied to the production of such anaesthesia.

It has often been stated that in hypnosis the senses may be rendered extraordinarily acute or hyperaesthetic, so that impressions too faint to affect the senses of the normal person may be perceived by the hypnotized subject; but in view of the fact that most observers are ignorant of the normal limits of sensitivity and discrimination, all such statements must be received with caution, until we have more convincing evidence than has yet been brought forward.

Positive and Negative Hallucinations are among the most striking effects of hypnotic suggestion. A good subject may be made to experience an hallucinatory perception of almost any object, the more easily the less unusual and out of harmony with the surroundings is the suggested object. He may, *e.g.*, be given a blank card and asked if he thinks it a good photograph of himself. He may then assent and describe the photograph in some detail, and, what is more astonishing, he may pick out the card as the one bearing the photograph, after it has been mixed with other similar blank cards. This seems to be due to the part played by *points de repère*, insignificant details of surface or texture, which serve as an objective basis around which the hallucinatory image is constructed by the pictorial imagination of the subject. A negative hallucination may be induced by telling the subject that a certain object or person is no longer present, when he ignores in every way that object or person. This is more puzzling than the positive hallucination and will be referred to again in discussing the theory of hypnosis. Both kinds of hallucination tend to be systematically and logically developed; if, *e.g.*, the subject is told that a certain person is no longer visible, he may become insensitive to impressions made on any sense by that person.

Delusions, or false beliefs as to their present situation or past experiences may be induced in many subjects. On being assured that he is some other person, or that he is in some strange situation, the subject may accept the suggestion and adapt his behaviour with great histrionic skill to the induced delusion. It is probable that many, perhaps all, subjects are vaguely aware, as we sometimes are in dreams, that the delusions and hallucinations they experience are of an unreal nature. In the lighter stages of hypnosis a subject usually remembers the events of his waking life, but in the deeper stages he is apt, while remembering the events of previous hypnotic periods, to be incapable of recalling his normal life; but in this respect, as also in respect to the extent to which on awaking he remembers the events of the hypnotic period, the suggestions of the operator usually play a determining part.

Among the organic changes that have been produced by hypnotic suggestion are slowing or acceleration of the cardiac and respiratory rhythms; rise and fall of body-temperature through two or three degrees; local erythema and even inflammation of the skin with vesication or exudation of small drops of blood; evacuation of the bowel and vomiting; modifications of the secretory activity of glands, especially of the sweat-glands.

Post-hypnotic Effects.—Most subjects in whom any appreciable degree of hypnosis can be induced show some susceptibility to post-hypnotic suggestion, *i.e.*they may continue to be influenced, when restored to the fully waking state, by suggestions made during hypnosis, more especially if the operator suggests that this shall be the case; as a rule, the deeper the stage of hypnosis reached, the more effective are post-hypnotic suggestions. The therapeutic applications of hypnotism depend in the main upon this post-hypnotic continuance of the working of suggestions. If a subject is told that on awaking, or on a certain signal, or after the lapse of a given interval of time from the moment of awaking, he will perform a certain action, he usually feels some inclination to carry out the suggestion at the appropriate moment. If he remembers that the action has been suggested to him he may refuse to perform it, and if it is one repugnant to his moral nature, or merely one that would make him appear ridiculous, he may persist in his refusal. But if the action is of a simple and ordinary nature he will usually perform it, remarking that he cannot be comfortable till it is done. If the subject was deeply hypnotized and remembers nothing of the hypnotic period, he will carry out the post-hypnotic suggestion in almost every case, no matter how complicated or absurd it may be, so long as it is not one from which his normal self would be extremely averse; and he will respond appropriately to the suggested signals, although he is not conscious of their having been named; he will often perform the action in a very natural way, and will, if questioned, give some more or less adequate reason for it. Such actions, determined by post-hypnotic suggestions of which no conscious memory remains, may be carried out even after the lapse of many weeks or even months. Inhibitions of movement, anaesthesia, positive and negative hallucinations, and delusions may also be made to persist for brief periods after the termination of hypnosis; and organic effects, such as the action of the bowels, the oncoming of sleep and the cessation of pain, may be determined by post-hypnotic suggestion. In short, it may be said that in a good subject all the kinds of suggestion which will take effect during hypnosis will also be effective if given as post-hypnotic suggestions.

Theory of the Hypnotic State.—Very many so called theories of hypnosis have been propounded, but few of them demand serious consideration. One author ascribes all the symptoms to cerebral anaemia, another to cerebral congestion, a third to temporary suppression of the functions of the cerebrum, a fourth to abnormal cerebral excitability, a fifth to the independent functioning of one hemisphere. Another seeks to explain all the facts by saying that in hypnosis our normal consciousness disappears and is replaced by a dream-consciousness; and yet another by the assumption that every human organism comprises two mental selves or personalities, a normal one and one which only comes into activity during sleep and hypnosis. Most of these "theories" would, even if true, carry us but a little way towards a complete understanding of the facts. There is, however, one theory or principle of explanation which is now gradually taking shape under the hands of a number of the more penetrating workers in this field, and which does seem to render intelligible many of the principle facts. This is the theory of *mental dissociation.*

It is clear that a theory of hypnosis must attempt to give some account of the peculiar condition of the brain which is undoubtedly present as an essential feature of the state. It is therefore not enough to say with Bernheim that hypnosis is a state of abnormally increased suggestibility produced by suggestion; nor is it enough, though it is partially true, to say that it is a state of mono-ideism or one of abnormally great concentration of attention. Any theory must be stated in terms of physiological psychology, it must take account of both the psychical and the nervous peculiarities of the hypnotic state; it must exhibit the physiological condition as in some degree similar to that obtaining in normal sleep; but principally it must account for that abnormally great receptivity for ideas, and that abnormally intense and effective operation of ideas so received, which constitute abnormally great suggestibility.

The theory of mental dissociation may be stated in purely mental terms, or primarily in terms of nervous structure and function; and the latter mode of statement is probably the more profitable at the present time. The increased effectiveness of ideas might be due to one of two conditions: (1) it might be that certain tracts of the brain or the whole brain were in a condition of abnormally great excitability; or (2) an idea might operate more effectively in the mind and on the body, not because it, or the underlying brain-process was more intense than normally, but because it worked out its effects free from the interference of contrary or irrelevant ideas that might weaken its force. It is along this second line that the theory of mental dissociation attempts to explain the increased suggestibility of hypnosis. To understand the theory we must bear in mind the nature of mental process in general and of its nervous concomitants. Mental process consists in the interplay, not merely of ideas, but rather of complex dispositions which are the more or less enduring conditions of the rise of ideas to consciousness. Each such disposition seems capable of remaining inactive or quiescent for long periods, and of being excited in various degrees, either by impressions made upon the sense-organs or by the spread of excitement from other dispositions. When its excitement rises above a certain pitch of intensity, the corresponding idea rises to the focus of consciousness. These dispositions are essential factors of all mental process, the essential conditions of all mental retention. They may be called simply mental dispositions, their nature being left undefined; but for our present purpose it is advantageous to regard them as neural dispositions, complex functional groups of nervous elements or neurones. The neurones of each such group must be conceived as being so intimately connected with one another that the excitement of any part of the group at once spreads through the whole group or disposition, so that it always functions as a unit. The whole cerebrum must be conceived as consisting of a great number of such dispositions, inextricably interwoven, but interconnected in orderly fashion with very various degrees of intimacy; groups of dispositions are very intimately connected to form neural systems, so that the excitement of any one member of such a system tends to spread in succession to all the other members. On the other hand, it is a peculiarity of the reciprocal relations of all such dispositions and systems that the excitement of any one to such a degree that the corresponding idea rises to consciousness prevents or inhibits the excitement of others, *i.e.* all of them are in relations of reciprocal inhibition with one another (see MUSCLE AND NERVE). The excitement of dispositions associated together to form a system tends towards some end which, either immediately or remotely, is an action, a bodily movement, in many cases a movement of the organs of speech only. Now we know from many exact experiments that the neural dispositions act and react upon one another to some extent, even when they are excited only in so feeble a degree that the corresponding ideas do not rise to consciousness. In the normal state of the brain, then, when any idea is present to consciousness, the corresponding neural disposition is in a state of dominant excitement, but the intensity of that excitement is moderated, depressed or partially inhibited by the sub-excitement of many rival or competing dispositions of other systems with which it is connected. Suppose now that all the nervous connexions between the multitudinous dispositions of the cerebrum are by some means rendered less effective, that the association-paths are partially blocked or functionally depressed; the result will be that, while the most intimate connexions, those between dispositions of any one system remain functional or permeable, the weaker less intimate connexions, those between dispositions belonging to different systems will be practically abolished for the time being; each system of dispositions will then function more or less as an isolated system, and its activity will no longer be subject to the depressing or inhibiting influence of other systems; therefore each system, on being excited in any way, will tend to its end with more than normal force, being freed from all interferences; that is to say, each idea or system of ideas will tend to work itself out and to realize itself in action immediately, without suffering the opposition of antagonistic ideas which, in the normal state of the brain, might altogether prevent its realization in action.

The theory of mental dissociation assumes that the abnormal state of the brain that obtains during hypnosis is of this kind, a temporary functional depression of all, or of many of the associations or nervous links between the neural dispositions; that is, it regards hypnosis as a state of *relative dissociation.* The lighter the stage of hypnosis the slighter is the degree of dissociation, the deeper the stage the more nearly complete is the dissociation.

It is not essential that the theory should explain in what change this stage of dissociation consists, but a view compatible with all that we know of the functions of the central nervous system may be suggested. The connexions between neural dispositions involve synapses or cell-junctions, and these seem to be the places of variable resistance which demarcate the dispositions and systems; and there is good reason to think that their resistances vary with the state of the neurones which they connect, being lowered when these are excited and raised when their excitement ebbs. Now, in the waking state, the varied stimuli, which constantly rain upon all the sense-organs, maintain the whole cerebrum in a state of sub-excitement, keep all the cerebral neurones partially charged with free nervous energy. When the subject lies down to sleep or submits himself to the hypnotizer he arrests as far as possible the flow of his thoughts, and the sensory stimuli are diminished in number and intensity. Under these conditions the general cerebral activity tends to subside, the free energy with which the cerebral neurones are charged ebbs away, and the synaptic resistances rise proportionally; then the effect of sensory impressions tends to be confined to the lower nervous level, and the brain tends to come to rest. If this takes place the condition of normal sleep is realized. But in inducing hypnosis the operator, by means of his words and manipulations, keeps one system of ideas and the corresponding neural system in activity, namely, the ideas connected with himself; thus he keeps open one channel of entry to the brain and mind, and through this one open channel he can introduce whatever ideas he pleases; and the ideas so introduced then operate with abnormally great effect because they work in a free field, unchecked by rival ideas and tendencies.

This theory of relative dissociation has two great merits: in the first place it goes far towards enabling us to understand in some degree most of the phenomena of hypnosis; secondly, we have good evidence that dissociation really occurs in deep hypnosis and in some allied states. Any one may readily work out for himself the application of the theory to the explanation of the power of the operator's suggestions to control movement, to induce anaesthesia, hallucinations and delusions, and to exert on the organic processes an influence greater than can be exerted by mental processes in the normal state of the brain. But the positive evidence of the occurrence of dissociation is a matter of great psychological interest and its nature must be briefly indicated. The phenomena of automatic speech and writing afford the best evidence of cerebral dissociation. Many persons can, while in an apparently normal or but very slightly abnormal condition, produce automatic writing, *i.e.* intelligibly written sentences, in some cases long connected passages, of whose import they have no knowledge, their self-conscious intelligence being continuously directed to some other task. The carrying out of post-hypnotic suggestions affords in many cases similar evidence. Thus a subject may be told that after waking he will perform some action when a given signal, such as a cough, is repeated for the fifth time. In the post-hypnotic state he remains unaware of his instructions, is not conscious of noting the signals, and yet carries out the suggestion at the fifth signal, thereby proving that the signals have been in some sense noted and counted. Many interesting varieties of this experiment have been made, some of much greater complexity; but all agreeing in indicating that the suggested action is prepared for and determined by cerebral processes that do not affect the consciousness of the subject, but seem to occur as a system of processes detached from the main stream of cerebral activity; that is to say, they imply the operation of relatively dissociated neural systems.

Many authorities go further than this; they argue that, since actions of the kind described are determined by processes which involve operations, such as counting, that we are accustomed to regard as distinctly mental in character and that normally involve conscious activity, we must believe that in these cases also consciousness or psychical activity is involved, but that it remains as a separate system or stream of consciousness concurrent with the normal or personal consciousness.

In recent years the study of various abnormal mental states, especially the investigations by French physicians of severe forms of hysteria, have brought to light many facts which seem to justify this assumption of a secondary stream of consciousness, a co- or sub-consciousness coexistent with the personal consciousness; although, from the nature of the case, an absolute proof of such co-consciousness can hardly be obtained. The co-consciousness seems to vary in degree of complexity and coherence from a mere succession of fragmentary sensations to an organized stream of mental activity, which may rival in all respects the primary consciousness; and in cases of the latter type it is usual to speak of the presence of a secondary personality. The co-consciousness seems in the simpler cases, *e.g.* in cases of hysterical or hypnotic anaesthesia, to consist of elements split off from the normal primary consciousness, which remains correspondingly poorer; and the assumption is usually made that such a stream of co-consciousness is the psychical correlate of groups and systems of neurones dissociated from the main mass of cerebral neurones. If, in spite of serious objections, we entertain this conception, we find that it helps us to give some account of various hypnotic phenomena that otherwise remain quite inexplicable; some such conception seems to be required more particularly by the facts of negative hallucination and the execution of post-hypnotic suggestions involving such operations as counting and exact discrimination without primary consciousness.

Supernormal Hypnotic Phenomena.—The facts hitherto considered, strange and perplexing as many of them are, do not seem to demand for their explanation any principles of action fundamentally different from those operative in the normal human mind. But much of the interest that has centred in hypnotism in recent years has been due to the fact that some of its manifestations seem to go beyond all such principles of explanation, and to suggest the reality of modes of influence and action that science has not hitherto recognized. Of these by far the best attested are the post-hypnotic unconscious reckoning of time and telepathy or "thought-transference" (for the latter see TELEPATHY). The post-hypnotic reckoning and noting of the lapse of time seems in some instances to have been carried out, in the absence of all extraneous aids and with complete unconsciousness on the part of the normal personality, with such extreme precision that the achievement cannot be accounted for by any intensification of any faculty that we at present recognize or understand. Thus, Dr Milne Bramwell has reported the case of a patient who, when commanded in hypnosis to perform some simple action after the lapse of many thousands of minutes, would carry out the suggestion punctually to the minute, without any means of knowing the exact time of day at which the suggestion was given or the time of day at the moment its performance fell due; more recently a similar case, even more striking in some respects, has been carefully observed and described by Dr T. W. Mitchell. Other reported phenomena, such as telaesthesia or clairvoyance, and telekinesia, are hardly sufficiently well attested to demand serious consideration in this place.

Medical Applications of Hypnotism.—The study and practice of hypnotism is not yet, and probably never will be, regarded as a normal part of the work of the general practitioner. Its successful application demands so much time, tact, and special experience, that it will probably remain, as it is now, and as it is perhaps desirable that it should remain, a specialized branch of medical practice. In England it is only in recent years that it has been possible for a medical man to apply it in his practice without incurring professional odium and some risk of loss of reputation. That, in certain classes of cases, it may effect a cure or bring relief when all other modes of treatment are of no avail is now rapidly becoming recognized; but it is less generally recognized that it may be used with great advantage as a supplement to other modes of treatment in relieving symptoms that are accentuated by nervous irritability or mental disturbance. A third wide field of usefulness lies before it in the cure of undesirable habits of many kinds. Under the first heading may be put insomnia, neuralgia, neurasthenia, hysteria in almost all its many forms; under the second, inflammations such as that of chronic rheumatism, contractures and paralyses resulting from gross lesion of the brain, epilepsy, dyspepsia, menstrual irregularities, sea-sickness; under the third, inebriety, the morphia and other drug habits, nail-biting, *enuresis nocturna*, masturbation, constipation, facial and other twitchings. In pronounced mental diseases hypnotism seems to be almost useless; for in general terms it may be said that it can be applied most effectively where the brain, the instrument through which it works, is sound and vigorous. The widespread prejudice against the use of hypnotism is no doubt largely due to the marvellous and (to most minds) mysterious character of the effects producible by its means; and this prejudice may be expected to diminish as our insight into the mode of its operation deepens. The more purely bodily results achieved by hypnotic suggestion become in some degree intelligible if we regard it as a powerful means of diverting nervous energy from one channel or organ to others, so as to give physiological rest to an overworked organ or tissue, or so as to lead to the atrophy of one nervous habit and the replacement of it by a more desirable habit. And in the cure of those disorders which involve a large mental element the essential part played by it is to drive out some habitually recurrent idea and to replace it by some idea, expectation or conviction of healthy tendency.

It seems clear that the various systems of "mind-curing" in the hands of persons lacking all medical training, which are now so frequently the cause of distressing and needless disasters, owe their rapid spread to the fact that the medical profession has hitherto neglected to attach sufficient importance to the mental factor in the causation and cure of disease; and it seems clear, too, that a more general and more intelligent appreciation of the possibilities of hypnotic treatment would constitute the best means at the disposal of the profession for combating this growing evil.

The Dangers of Hypnotism.—Much has been written on this head of late years, and some of the enthusiastic advocates of hypnotic treatment have done harm to their cause by ignoring or denying in a too thoroughgoing manner the possibility of undesirable results of the spread of the knowledge and practice of hypnotism. Like all powerful agencies, chloroform or morphia, dynamite or strong electric currents, hypnotic suggestion can only be safely used by those who have special knowledge and experience, and, like them, it is liable to abuse. There is little doubt that, if a subject is repeatedly hypnotized and made to entertain all kinds of absurd delusions and to carry out very frequently posthypnotic suggestions, he may be liable to some ill-defined harm; also, that an unprincipled hypnotizer might secure an undue influence over a naturally weak subject.

But there is no ground for the belief that hypnotic treatment, applied with good intentions and reasonable care and judgment, does or can produce deleterious effects, such as weakening of the will or liability to fall spontaneously into hypnosis. All physicians of large experience in hypnotic practice are in agreement in respect to this point. But some difference of opinion exists as to the possibility of deliberately inducing a subject to commit improper or criminal actions during hypnosis or by posthypnotic suggestion. There is, however, no doubt that subjects retain even in deep hypnosis a very considerable power of resistance to any suggestion that is repugnant to their moral nature; and it has been shown that, on some cases in which a subject in hypnosis is made to perform some ostensibly criminal action, such as firing an unloaded pistol at a bystander or putting poison into a cup for him to drink, he is aware, however obscurely, of the unreal nature of the situation. Nevertheless it must be admitted that a person lacking in moral sentiments might be induced to commit actions from which in the normal state he would abstain, if only from fear of punishment; and it is probable that a skilful and evil-intentioned operator could in some cases so deceive a well-disposed subject as to lead him into wrong-doing. The proper precaution against such dangers is legislative regulation of the practice of hypnotism such as is already enforced in some countries.

Bibliography.—The literature of hypnotism has increased in volume at a rapid rate during recent years. Of recent writings the following may be mentioned as among the most important:—*Treatment by Hypnotism and Suggestion* by C. Lloyd Tuckey, M.D. (5th ed., London, 1907); *Hypnotism, its History, Practice and Theory*, by J. Milne Bramwell, M.B. (2nd ed., London, 1906); *Hypnotism*, by Albert Moll (5th ed., London, 1901). All these three books give good general accounts of hypnotism, the first being the most strictly medical, the last the most general in its treatment. See also *Hypnotism: or Suggestion in Psycho-Therapy*, by August Forel (translated from the 5th German ed. by G. H. W. Armit, London, 1906); a number of papers by Ed. Gurney, and by Ed. Gurney and F.W.H. Myers in *Proc. of the Soc. for Psychical Research*, especially "The Stages of Hypnotism," in vol. ii.; also some more recent papers in the same journal by other hands; chapter on Hypnotism in *Human Personality and its Survival of bodily Death*, by F. W. H. Myers (London, 1903); *The Psychology of Suggestion*, by Boris Sidis, Ph.D. (New York, 1898); "Zur Psychologie der Suggestion," by Prof. Th. Lipp, and other papers in the *Zeitschrift für Hypnotismus*. Of special historical interest are the following:—*Étude sur le zoomagnétisme*, par A. A. Liébeault (Paris, 1883); *Hypnotisme, suggestion, psycho-thérapie*, par Prof. Bernheim (Paris, 1891); *Braid on Hypnotism* (a new issue of James Braid's *Neurypnology*), edited by A. E. Waite (London, 1899); *Traité du somnambulisme*, by A. Bertrand (Paris, 1826). A full bibliography is appended to Dr Milne Bramwell's *Hypnotism*. (W. McD.)

HYPOCAUST (Gr. ὑπόκαυστον: ὑπό, beneath, and καυεῖν, to burn), the term given to the chamber formed under the floors of the Roman baths, through which the hot air from the furnace passed, sometimes to a single flue, as in the case of the *tepidarium*, but in the *calidarium* and sweating-room to a series of flues placed side by side forming the lining of the walls. The floor of the hot-air chamber consisted of tiles, 2 ft. square, laid on a bed of concrete; on this a series of dwarf piers 2 ft. high were built of 8-in. square tiles placed about 16 in. apart, which carried the floor of the hall or room; this floor was formed of a bed of concrete covered with layers of pounded bricks and marble cement, on which the marble pavement in slabs or tesserae was laid. In colder countries, as for instance in Germany and England, the living rooms were all heated in a similar way, and round Trèves (Trier) both systems have been found in two or three Roman villas, with the one flue for the ordinary rooms and several wall flues for the hot baths. In England these hypocausts are found in every Roman settlement, and the chief interest in these is centred in the magnificent mosaic pavements with which the principal rooms were laid. Many of the pavements found in London and elsewhere have been preserved in the British or the Guildhall museums; and in some of the provincial towns, such as Leicester and Lincoln, they remain *in situ* many feet below the present level of the town.

HYPOCHONDRIASIS (synonyms— "the spleen," "the vapours"), a medical term (from τὸ ὑποχόνδριον, τὰ ὑποχόνδρια, the soft part of the body immediately under the χόνδρος or cartilage of the breast-bone) given by the ancients, and indeed by physicians down to the time of William Cullen, to diseases or derangements of one or more of the abdominal viscera. Cullen (*Clinical Lectures*, 1777) classified it amongst nervous diseases, and Jean Pierre Falret (1794–1870) more fully described it as a morbid condition of the nervous system characterized by depression of feeling and false beliefs as to an impaired state of the health. The subjects of hypochondriasis are for the most part members of families in which hereditary predisposition to degradation of the nervous system is strong, or those who have suffered from morbid influences affecting this system during the earlier years of life. It may be dependent on depressing disease affecting the general system, but under such circumstances it is generally so complicated with the symptoms of hysteria as to render differentiation difficult (see Hysteria). Hypochondriasis is often handed down from one generation to another in its individual form, but it is also not unfrequently to be met with in an individual as the sole manifestation in him of a family tendency to insanity. In its most common form it is manifested by simple false belief as to the state of the health, the intellect being otherwise unaffected. We may instance the "vapourish" woman or the "splenetic" as terms society has applied to its milder manifestations. Such persons are constantly asserting a weak state of health although no palpable cause can be discovered. In its more definite phases pain or uneasy sensations are referred by the patient to some particular region, generally the abdomen, the heart or the head. That these are subjective is apparent from the fact that the general health is good: all the functions of the various systems are duly performed; the patient eats and sleeps well; and, when any circumstance temporarily overrides the false belief, he is happy and comfortable. No appeal to the reason is of any avail, and the hypochondriac idea so dominates his existence as to render him unable to perform the ordinary duties of life. In its most aggravated form hypochondriasis amounts to actual insanity, delusions arising as to the existence of living creatures in the intestines or brain, or to the effect that the body is materially changed; *e.g.* into glass, wood, &c. The symptoms of this condition may be remittent; they may even disappear for years, and only return on the advent of some exciting cause. Suicide is occasionally committed in order to escape from the constant misery. Recovery can only be looked for by placing the patient under such morally hygienic conditions as may help to turn his mind to other matters. (See also Neuropathology.)

HYPOCRISY, pretence, or false assumption of a high character, especially in regard to religious belief or practice. The Greek ὑπόκρισις, from which the word is derived through the Old French, meant primarily the acting of a part on the stage, from ὑποκρίνεσθαι, to give an answer, to speak dialogue, play a part on the stage, hence to practice dissimulation.

HYPOSTASIS, in theology, a term frequently occurring in the Trinitarian controversies of the 4th and 5th centuries. According to Irenaeus (i. 5, 4) it was introduced into theology by Gnostic writers, and in earliest ecclesiastical usage appears, as among the Stoics, to have been synonymous with οὐσία. Thus Dionysius of Rome (cf. Routh, *Rel. Sacr.* iii. 373) condemns the attempt to sever the Godhead into three separate *hypostases* and three deities, and the Nicene Creed in the anathemas speaks of ἑξέτερας ὑποστάσεως ἢ οὐσίας. Alongside, however, of this persistent interchange there was a desire to distinguish between the terms, and to confine ὑπόστασις to the Divine *persons.* This tendency arose in Alexandria, and its progress may be seen in comparing the early and later writings of Athanasius. That writer, in view of the Arian trouble, felt that it was better to speak of οὐσία as "the common undifferentiated substance of Deity," and ὑπόστασις as "Deity existing in a personal mode, the substance of Deity with certain special properties" (οὐσία μετά τινων ἰδιωμάτων). At the council of Alexandria in 362 the phrase τρεῖς ὑποστάσεις was permitted, and the work of this council was supplemented by Basil, Gregory of Nazianzus and Gregory of Nyssa in the formula μία οὐσία, τρεῖς ὑποστάσεις or μία οὐσία ἐν τρίσιν ὑποστάσεσιν.

The results arrived at by these Cappadocian fathers were stated in a later age by John of Damascus (*De orth. fid.* iii. 6), quoted in R. L. Ottley, *The Doctrine of the Incarnation*, ii. 257.

HYPOSTYLE, in architecture, the term applied to a hall, the flat ceiling of which is supported by columns, as in the Hall of Columns at Karnak. In this case the columns flanking the central avenue are of greater height than those of the side aisles, and this admits of openings in the wall above the smaller columns, through which light is admitted over the aisle roof, through clerestory windows.

HYPOSULPHITE OF SODA, the name originally given to the substance known in chemistry as sodium thiosulphate, $Na_2S_2O_3$; the earlier name is still commonly used, especially by photographers, who employ this chemical as a fixer. In systematic chemistry, sodium hyposulphite is a salt of hyposulphurous acid, to which Schutzenberger gave the formula H_2SO_2, but which Bernthsen showed to be $H_2S_2O_4$. (See SULPHUR.)

HYPOTHEC (Lat. *hypotheca*, Gr. ὑποθήκη), in Roman law, the most advanced form of the contract of pledge. A specific thing may be given absolutely to a creditor on the understanding that it is to be given back when the creditor's debt is paid; or the property in the thing may be assigned to the creditor while the debtor is allowed to remain in possession, the creditor as owner being able to take possession if his debt is not discharged. Here we have the kind of security known as pledge and mortgage respectively. In the *hypotheca*, the property does not pass to the creditor, nor does he get possession, but he acquires a preferential right to have his debt paid out of the hypothecated property; that is, he can sell it and pay himself out of the proceeds, or in default of a purchaser he can become the owner himself. The name and the principle have passed into the law of Scotland, which distinguishes between conventional hypothecs, as *bottomry* and *respondentia*, and tacit hypothecs established by law. Of the latter the most important is the landlord's hypothec for rent (corresponding to distress in the law of England), which extends over the produce of the land and the cattle and sheep fed on it, and over stock and horses used in husbandry. The law of agricultural hypothec long caused much discontent in Scotland; its operation was restricted by the Hypothec Amendment (Scotland) Act 1867, and finally by the Hypothec Abolition (Scotland) Act 1880 it was enacted that the "landlord's right of hypothec for the rent of land, including the rent of any buildings thereon, exceeding two acres in extent, let for agriculture or pasture, shall cease and determine." By the same act and by the Agricultural Holdings (Scotland) Act 1883 other rights and remedies for rent, where the right of hypothec had ceased, were given to the landlord.

HYPOTHESIS (from Gr. ὑποτιθέναι, to put under; cf. Lat. *suppositio*, from *sub-ponere*), in ordinary language, an explanation, supposition or assumption, which is put forward in the absence of ascertained facts or causes. Both in ordinary life and in the acquisition of scientific knowledge hypothesis is all-important. A detective's work consists largely in forming and testing hypothesis. If an astronomer is confronted by some phenomenon which has no obvious explanation he may postulate some set of conditions which from his general knowledge of the subject would or might give rise to the phenomenon in question; he then tests his hypothesis until he discovers whether it does or does not conflict with the facts. An example of this process is that of the discovery of the planet Neptune: certain perturbations of the orbit of Uranus had been observed, and it was seen that these could be explained on the hypothesis of the existence of a then unknown planet, and this hypothesis was verified by actual observation. The progress of inductive knowledge is by the formation of successive hypotheses, and it frequently happens that the demolition of one or even many hypotheses is the direct road to a new and accurate hypothesis, *i.e.* to fresh knowledge. A hypothesis may, therefore, turn out to be entirely wrong, yet it may be of the greatest practical use.

The recognition of the importance of hypotheses has led to various attempts at drawing up exact rules for their formation, but logicians are generally agreed that only very elementary principles can be laid down. Thus a hypothesis must contain nothing which is at variance with known facts or principles: it should not postulate conditions which cannot be verified empirically. J. S. Mill (*Logic* III. xiv. 4) laid down the principle that a hypothesis is not "genuinely scientific" if it is "destined always to remain a hypothesis": it must "be of such a nature as to be either proved or disproved by comparison with observed facts": in the same spirit Bacon said that in searching for causes in nature "Deum semper excipimus." Mill's principle, though sound in the abstract, has, except in a few cases, little practical value in determining the admissibility of hypotheses, and in practice any rule which tends to discourage hypothesis is in general undesirable. The most satisfactory check on hypothesis is expert knowledge in the particular field of research by which rigorous tests may be applied. This test is roughly of two kinds, first by the ultimate principles or presuppositions on which a particular branch of knowledge rests, and second by the comparison of correlative facts. Useful light is shed on this distinction by Lotze, who contrasts (*Logic*, § 273) *postulates* ("absolutely necessary assumptions without which the content of the observation with which we are dealing would contradict the laws of our thought") with *hypotheses*, which he defines as conjectures, which seek "to fill up the postulate thus abstractly stated by specifying the concrete causes, forces or processes, out of which the given phenomenon really arose in this particular case, while in other cases maybe the same postulate is to be satisfied by utterly different though equivalent combinations of forces or active elements." Thus a hypothesis may be ruled out by principles or postulates without any reference to the concrete facts which belong to that division of the subject to explain which the hypothesis is formulated. A true hypothesis, therefore, seeks not merely to connect or colligate two separate facts, but to do this in the light of and subject to certain fundamental principles. Various attempts have been made to classify hypotheses and to distinguish "hypothesis" from a "theory" or a mere "conjecture": none of these have any great practical importance, the differences being only in degree, not in kind.

The adjective "hypothetical" is used in the same sense, both loosely in contradistinction to "real" or "actual," and technically in the phrases "hypothetical judgment" and "hypothetical syllogism." (See LOGIC and SYLLOGISM.)

See Naville, *La Logique de l'hypothèse* (1880), and textbooks of logic, *e.g.* those of Jevons, Bosanquet, Joseph; Liebmann, *Der Klimax d. Theorien.*

HYPOTRACHELIUM (Gr. ὑποτραχήλιον, the lower part of the neck, τράχηλος), in classical architecture, the space between the annulet of the echinus and the upper bed of the shafts, including, according to C. R. Cockerell, the three grooves or sinkings found in some of the older examples, as in the temple of Neptune at Paestum and the temple of Aphaea at Aegina; there being only one groove in the Parthenon, the Theseum and later examples. In the temple of Ceres and the so-called Basilica at Paestum the hypotrachelium consists of a concave sinking carved with vertical lines suggestive of leaves, the tops of which project forward. A similar decoration is found in the capital of the columns flanking the tomb of Agamemnon at Mycenae, but here the hypotrachelium projects forward with a cavetto moulding, and is carved with triple leaves like the buds of a rose. In the Roman Doric Order the term was sometimes applied to that which is generally known as the "necking," the space between the fillet and the annulet.

HYPSOMETER (Gr. ὕψος, height, μέτρον, a measure), an instrument for measuring heights which employs the principles that the boiling-point of a liquid is lowered by diminishing the pressure, and that the barometric pressure varies with the height of the point of observation. The instrument consists of a cylindrical vessel in which the liquid, usually water, is boiled, surmounted by a jacketed column, in the outer partitions of which the vapour circulates, while in the central one a thermometer is placed. To deduce the height of the station from the observed boiling-point, it is necessary to know the relation existing between the boiling-point and pressure, and also between the pressure and height of the atmosphere.

HYRACOIDEA, a suborder of ungulate mammals represented at the present day only by the Syrian hyrax (*Procavia syriaca*), the "coney" of the Bible, and its numerous African relatives, all of which may be included in the single genus *Procavia* (or *Hyrax*), and consequently in the family *Procaviidae*. These creatures have no proper English name, and are generally known as hyraxes, from the scientific term (*Hyrax*) by which they were for many years designated—a term which has unfortunately had to give place to the earlier *Procavia*. In size these animals may be compared roughly to rabbits and hares; and they have rodent-like habits, hunching up their backs after the fashion of some foreign members of the hare-family, more especially the Liu-Kiu rabbit. In the matter of nomenclature these animals have been singularly unfortunate. In the title "hyrax" they have, for instance, usurped the Greek name for the shrew-mouse; while in the Bible they have been given the old English name for the rabbit. Perhaps rock-rabbit would be the best name. At the Cape they are known to the Dutch as *dass* (badger), which has been anglicized into "dassie."

As regards the recent forms, the dentition in the fully adult animal consists only of incisors and cheek-teeth, the formula being $i.\ \frac{1}{2}$, $c.\ \frac{0}{0}$, $p.\ \frac{4}{4}$, $m.\ \frac{3}{3}$. There is, however, a minute upper canine developed at first, which is early shed; and in extinct forms this tooth was

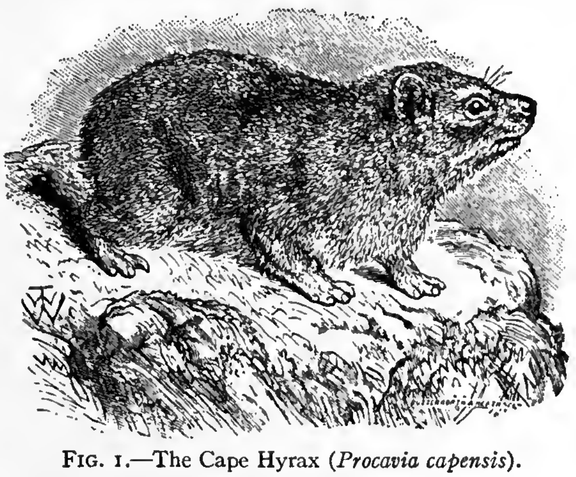

FIG. 1.—The Cape Hyrax (*Procavia capensis*).

functional and molar-like. The upper incisors have persistent pulps, and are curved longitudinally, forming a semicircle as in rodents; they are, however, not flattened from before backwards as in that order, but prismatic, with an antero-external, an antero-internal and a posterior surface, the first two only being covered with enamel; their tips are consequently not chisel-shaped, but sharp-pointed. They are preceded by functional, rooted milk-teeth. The lower incisors have long tapering roots, but not of persistent growth; and are straight, directed somewhat forwards, with awl-shaped, tri-lobed crowns. Behind the incisors is a considerable gap, followed by the cheek-teeth, which are all contiguous, and formed almost exactly on the pattern of some of the perissodactyle ungulates. The milk-dentition includes three pairs of incisors and one of canines in each jaw. The hyoid arch is unlike that of any known mammal. The dorsal and lumbar vertebrae are very numerous, 28 to 30, of which 21 or 22 bear ribs. The tail is extremely short. There are no clavicles. In the fore foot, the three middle toes are subequally developed, the fifth is present, but smaller, and the first is rudimentary, although, in one species at least, all its normal bones are present. The terminal phalanges of the four outer digits are small, somewhat conical and flattened in form. The carpus has a distinct os centrale. There is a slight ridge on the femur in the place of a third trochanter. The fibula is complete, thickest at its upper end, where it generally unites with the tibia. The articulation between the tibia and astragalus is more complex than in other mammals, the end of the malleolus entering into it. The hind-foot is very like that of a rhinoceros, having three well-developed toes. There is no trace of a first toe, and the fifth metatarsal is represented by a small nodule. The terminal phalange of the inner (or second) digit is deeply cleft, and has a peculiar long curved claw, the others having short broad nails. The stomach is formed upon much the same principle as that of the horse or rhinoceros, but is more elongated transversely and divided by a constriction into two cavities—a large left *cul de sac*, lined by a very dense white epithelium, and a right pyloric cavity, with a thick, soft, vascular lining. The intestinal canal is long, and has, in addition to the ordinary short, but capacious and sacculated caecum at the commencement of the colon, lower down, a pair of large, conical, pointed caeca. The liver is much subdivided, and there is no gall-bladder. The brain resembles that of typical ungulates far more than that of rodents. The testes are permanently abdominal. The ureters open into the fundus of the bladder as in some Rodents. The

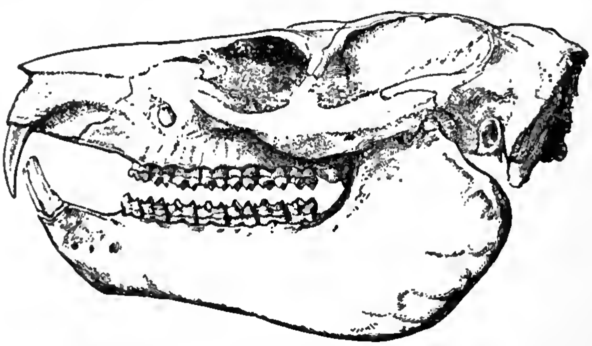

FIG. 2.—Skull and Dentition of Tree-Hyrax (*Procavia dorsalis*) $\times \frac{2}{3}$.

female has six teats, of which four are inguinal and two axillary, and the placenta is zonary and deciduous. There is a gland on the back.

The more typical members of the genus are terrestrial in their habits, and their cheek-teeth have nearly the same pattern as in rhinoceroses; while the interval between the upper incisors is less than the width of the teeth; and the lower incisors are only slightly notched at the cutting edge. Vertebrae: C. 7, D. 22, L. 8, S. 6, C. 6. Of this form the earliest known species, *P. capensis*, is the type; but there are many other species, as *P. syriaca*, and *P. brucei* from Syria and eastern Africa. They inhabit mountainous and rocky regions, and live on the ground. In a second section the molar teeth have the same pattern as in *Palaeotherium* (except that the third lower molar has but two lobes); the interval between the upper incisors exceeds the width of the teeth; and the lower incisors have distinctly trilobed crowns. Vertebrae: C. 7, D. 21, L. 7, S. 5, C. 10. The members of this section frequent the trunks and large branches of trees, sleeping in holes. There are several species from Western and South Africa, as *P. arboreus* and *P. dorsalis*. The members of both groups appear to have a power like that possessed by geckos of clinging to vertical surfaces of rocks and trees by the soles of their feet.

Extinct Hyracoids.—For many years extinct representatives of the Hyracoidea were unknown, partly owing to the fact that certain fossils were not recognized as really belonging to that group. The longest known of these was originally named *Leptodon graecus*, but, on account of the preoccupation of the generic title, the designation has been changed to *Pliohyrax graecus*. This animal, whose remains occur in the Lower Pliocene of both Attica and Samos, was about the size of a donkey, and possessed three pairs of upper incisor teeth, of which the innermost were large and trihedral, recalling those of the existing genus. On the other hand, the two outer pairs of incisors were in contact with one another and with the canines, so as to form on each side a series continuous with the cheek-teeth.

The next representatives of the group occur in the Upper Eocene beds of the Fayum district of Egypt, where the genera *Saghatherium* and *Megalohyrax* occur. These are regarded as representing a distinct family, the *Saghatheriidae*, characterized by the possession of the full series of twenty-two teeth in the upper jaw, among which the first pair of incisors was modified to form trihedral rootless tusks, while the two remaining pairs were separated from one another and from the teeth in front by gaps. The canine was like a premolar, and in contact with the first tooth of that series; and the cheek-teeth were short-crowned, with the premolar simpler than the molars, and a third lobe to the last lower tooth of the latter series. The members of this genus were small or medium-sized ungulates with single-rooted incisors. On the other hand, the representatives of the contemporary genus *Megalohyrax* were approximately as large as *Pliohyrax*, and in some instances had double roots to the second and third incisors.

It is now possible to define the suborder Hyracoidea as including ungulates with a centrale in the carpus, plantigrade feet, in which the first and fifth toes are reduced in greater or less degree, and clavicles and a foramen in the lower end of the humerus are absent. The femur has a small third trochanter, the radius and ulna and tibia and fibula are respectively separate, at least in the young, and the fibula articulates with the astragalus. The earlier forms had the full series of 44 teeth, with the premolars simpler than the molars; but in the later types the canines and some of the incisors disappear, and at least the hinder premolars become molar-like. In all cases the first upper incisors are large and rootless.

That the group originated in Africa there can be no reasonable doubt; and it is remarkable that so early as the Upper Eocene the types in existence differed comparatively little in structure from the modern forms. In fact the hyraxes were then almost as distinct from other mammals as they are at the present day.

HYRCANIA. (1) An ancient district of Asia, south of the Caspian Sea, and bounded on the E. by the river Oxus, called *Virkana*, or "Wolf's Land," in Old Persian. It was a wide and indefinite tract. Its chief city is called Tape by Strabo, Zadracarta by Arrian (probably the modern Astarabad). The latter is evidently the same as Carta, mentioned by Strabo as an important city. Little is known of the history of the country. Xenophon says it was subdued by the Assyrians; Curtius that 6000 Hyrcanians were in the army of Darius III. (2) Two towns named Hyrcania are mentioned, one in Hyrcania, the other in Lydia. The latter is said to have derived its name from a colony of Hyrcanians, transported thither by the Persians.

HYRCANUS (Ὑρκανός), a Greek surname, of unknown origin, borne by several Jews of the Maccabaean period.

John Hyrcanus I., high priest of the Jews from 135 to 105 B.C., was the youngest son of Simon Maccabaeus. In 137 B.C. he, along with his brother Judas, commanded the force which repelled the invasion of Judaea led by Cendebeus, the general of Antiochus VII. *Sidetes*. On the assassination of his father and two elder brothers by Ptolemy, governor of Jericho, his brother-in-law, in February 135, he succeeded to the high priesthood and the supreme authority in Judaea. While still engaged in the struggle with Ptolemy, he was attacked by Antiochus with a large army (134), and compelled to shut himself up in Jerusalem; after a severe siege peace was at last secured only on condition of a Jewish disarmament, and the payment of an indemnity and an annual tribute, for which hostages were taken. In 129 he accompanied Antiochus as a vassal prince on his ill-fated Parthian expedition; returning, however, to Judaea before winter, he escaped the final disaster. By the judicious mission of an embassy to Rome he now obtained confirmation of the alliance which his father had previously made with the growing western power; at the same time he availed himself of the weakened state of the Syrian monarchy under Demetrius II. to overrun Samaria, and also to invade Idumaea, which he completely subdued, compelling its inhabitants to receive circumcision and accept the Jewish faith. After a long period of rest he directed his arms against the town of Samaria, which, in spite of the intervention of Antiochus, his sons Antigonus and Aristobulus ultimately took, and by his orders razed to the ground (*c.* 109 B.C.). He died in 105, and was succeeded by Aristobulus, the eldest of his five sons. The external policy of Hyrcanus was marked by considerable energy and tact, and, aided as it was by favouring circumstances, was so successful as to leave the Jewish nation in a position of independence and of influence such as it had not known since the days of Solomon. During its later years his reign was much distrubed, however, by the contentions for ascendancy which arose between the Pharisees and Sadducees, the two rival sects or parties which then for the first time (under those names at least) came into prominence. Josephus has related the curious circumstances under which he ultimately transferred his personal support from the former to the latter.

John Hyrcanus II., high priest from 78 to 40 B.C., was the eldest son of Alexander Jannaeus by his wife Alexandra, and was thus a grandson of the preceding. When his father died in 78, he was by his mother forthwith appointed high priest, and on her death in 69 he claimed the succession to the supreme civil authority also; but, after a brief and troubled reign of three months, he was compelled to abdicate both kingly and priestly dignities in favour of his more energetic and ambitious younger brother Aristobulus II. In 63 it suited the policy of Pompey that he should be restored to the high priesthood, with some semblance of supreme command, but of much of this semblance even he was soon again deprived by the arrangement of the pro-consul Gabinius, according to which Palestine was in 57 B.C. divided into five separate circles (σύνοδοι, συνέδρια). For services rendered to Caesar after the battle of Pharsalia, he was again rewarded with the sovereignty (προστασία τοῦ ἔθνους, Jos. *Ant.* xx. 10) in 47 B.C., Antipater of Idumaea, however, being at the same time made procurator of Judaea. In 41 B.C. he was practically superseded by Antony's appointment of Herod and Phasael to be tetrarchs of Judaea; and in the following year he was taken prisoner by the Parthians, deprived of his ears that he might be permanently disqualified for priestly office, and carried to Babylon. He was permitted in 33 B.C. to return to Jerusalem, where on a charge of treasonable correspondence with Malchus, king of Arabia, he was put to death in 30 B.C.

See Josephus (*Ant.* xiii. 8-10; xiv. 5-13; *Bell. Jud.* i. 2; i. 8-13). Also Maccabees, *History*. (J. H. A. H.)

HYSSOP (*Hyssopus officinalis*), a garden herb belonging to the natural order *Labiatae*, formerly cultivated for use in domestic medicine. It is a small perennial plant about 2 ft. high, with slender, quadrangular, woody stems; narrowly elliptical, pointed, entire, dotted leaves, about 1 in. long and $\frac{1}{3}$ in. wide, growing in pairs on the stem; and long terminal, erect, half-whorled, leafy spikes of small violet-blue flowers, which are in blossom from June to September. Varieties of the plant occur in gardens with red and white flowers, also one having variegated leaves. The leaves have a warm, aromatic, bitter taste, and are believed to owe their properties to a volatile oil which is present in the proportion of $\frac{1}{4}$ to $\frac{1}{2}$ %. Hyssop is a native of the south of Europe, its range extending eastward to central Asia. A strong tea made of the leaves, and sweetened with honey, was formerly used in pulmonary and catarrhal affections, and externally as an application to bruises and indolent swellings.

The hedge hyssop (*Gratiola officinalis*) belongs to the natural order *Scrophulariaceae*, and is a native of marshy lands in the south of Europe, whence it was introduced into Britain more than 300 years ago. Like *Hyssopus officinalis*, it has smooth opposite entire leaves, but the stems are cylindrical, the leaves twice the size, and the flowers solitary in the axils of the leaves and having a yellowish-red veined tube and bluish-white limb, while the capsules are oval and many-seeded. The herb has a bitter, nauseous taste, but is almost odourless. In small quantities it acts as a purgative, diuretic and emetic when taken internally. It was formerly official in the Edinburgh Pharmacopoeia, being esteemed as a remedy for dropsy. It is said to have formed the basis of a celebrated nostrum for gout, called *Eau médicinale*, and in former times was called *Gratia Dei.* When growing in abundance, as it does in some damp pastures in Switzerland, it becomes dangerous to cattle. G. *peruviana* is known to possess similar properties.

The hyssop (*'ezob*) of Scripture (Ex. xii. 22; Lev. xiv. 4, 6; Numb. xix. 6, 18; 1 Kings v. 13 (iv. 33); Ps. li. 9 (7); John xix. 29), a wall-growing plant adapted for sprinkling purposes, has long been the subject of learned disputation, the only point on which all have agreed being that it is not to be identified with the *Hyssopus officinalis*, which is not a native of Palestine. No fewer than eighteen plants have been supposed by various authors to answer the conditions, and Celsius has devoted more than forty pages to the discussion of their several claims. By Tristram (*Oxford Bible for Teachers*, 1880) and others the caper plant (*Capparis spinosa*) is supposed to be meant; but, apart from other difficulties, this identification is open to the objection that the caper seems to be, at least in one passage (Eccl. xii. 5), otherwise designated (*'abiyyônah*). Thenius (on 1 Kings v. 13) suggests *Orthotrichum saxatile*.

The most probable opinion would seem to be that found in Maimonides and many later writers, according to which the Hebrew *'ezob* is to be identified with the Arabic *sa'atar*, now understood to be *Satureja Thymus*, a plant of very frequent occurrence in Syria and Palestine, with which *Thymus Serpyllum*, or wild thyme, and *Satureja Thymbra* are closely allied. Its smell, taste and medicinal properties are similar to those of *H. officinalis*. In Morocco the *sa'atar* of the Arabs is *Origanum compactum*; and it appears probable that several plants of the genera *Thymus*, *Origanum* and others nearly allied in form and habit, and found in similar localities, were used under the name of hyssop.

HYSTASPES (the Greek form of the Persian *Vishtāspa*). (1) A semi-legendary king (*kava*), praised by Zoroaster as his protector and a true believer, son of Aurvataspa (Lohrasp). The later tradition and the Shahname of Firdousi makes him (in the modern form Kai Gushtāsp) king of Iran. As Zoroaster probably preached his religion in eastern Iran, Vishtāspa must have been a dynast in Bactria or Sogdiana. The Zoroastrian religion was already dominant in Media in the time of the Assyrian king Sargon (*c.* 715 B.C.), and had been propagated here probably in much earlier times (cf. PERSIA); the time of Zoroaster and Vishtāspa may therefore be put at *c.* 1000 B.C. (2) A Persian, father of Darius I., under whose reign he was governor of Parthia, as Darius himself mentions in the Behistun inscription (2. 65). By Ammianus Marcellinus, xxiii. 6. 32, and by many modern authors he has been identified with the protector of Zoroaster, which is equally impossible for chronological and historical reasons, and from the evidence of the development of Zoroastrianism itself (see PERSIA: *Ancient History*). (ED. M.)

HYSTERESIS (Gr. ὑστέρησις, from ὑστερεῖν, to lag behind), a term added to the vocabulary of physical science by J. A. Ewing, who defines it as follows: When there are two qualities M and N such that cyclic variations of N cause cyclic variations of M, then if the changes of M lag behind those of N, we may say that there is *hysteresis* in the relation of M to N (*Phil. Trans.*, 1885, 176, p. 524). The phenomenon is best known in connexion with magnetism. If an iron bar is subjected to a magnetic force which is first gradually increased to a maximum and then gradually diminished, the resulting magnetization of the bar for any given value of the magnetic force will be greater when the force is decreasing than when it is increasing; the iron always tends to retain the magnetic condition which it has previously acquired, and changes of its magnetization consequently lag behind changes of the magnetic force. Thus there is hysteresis in the relation of magnetization to magnetic force. In consequence of hysteresis the process of magnetizing a piece of iron to a certain intensity and then restoring it to its original condition, or of effecting a double reversal of its magnetization, involves the expenditure of energy, which is dissipated as heat in the iron. Electrical generators and transformers often contain pieces of iron the magnetization of which is reversed many times in a second, and in order to economize power and to avoid undue heating it is essential that hysteresis should in such cases be as small as possible. Iron and mild steels showing remarkably little hysteresis are now specially manufactured for use in the construction of electrical machinery. (See MAGNETISM.)

HYSTERIA, a term applied to an affection which may manifest itself by a variety of symptoms, and which depends upon a disordered condition of the highest nervous centres. It is characterized by psychical peculiarities, while in addition there is often derangement of the functions subserved by the lower cerebral and spinal centres. Histological examination of the nervous system has failed to disclose associated structural alterations.

By the ancients and by modern physicians down to the time of Sydenham the symptoms of hysteria were supposed to be directly due to disturbances of the uterus (Gr. ὑστέρα, whence the name). This view is now universally recognized to be erroneous. The term "functional" is often used by English neurologists as synonymous with hysterical, a nomenclature which is tentatively advantageous since it is at least non-committal. P. J. Möbius has defined hysteria as "a state in which ideas control the body and produce morbid changes in its functions." P. Janet, who has done much to popularize the psychical origin of the affection, holds that there is "a limitation of the field of consciousness" comparable to the contraction of the visual fields met with in the disease. The hysterical subject, according to this view, is incapable of taking into the field of consciousness all the impressions of which the normal individual is conscious. Strong momentary impressions are no longer controlled so efficiently because of the defective simultaneous impressions of previous memories. Hence the readiness with which the impulse of the moment is obeyed, the loss of emotional control and the increased susceptibility to external suggestion, which are so characteristic. A secondary subconscious mental state is engendered by the relegation of less prominent impressions to a lower sphere. The dual personality which is typically exemplified in somnambulism and in the hypnotic state is thus induced. The explanation of hysterical symptoms which are independent of the will, and of the existence of which the individual may be unaware, is to be found in a relative preponderance of this secondary subconscious state as compared with the primary conscious personality. An elaboration of this theory affords an explanation of hysterical symptoms dependent upon a "fixed idea." The following definition of hysteria has recently been advanced by J. F. F. Babinski: "Hysteria is a psychical condition manifesting itself principally by signs that may be termed primary, and in an accessory sense others that we may call secondary. The characteristic of the primary signs is that they may be exactly reproduced in certain subjects by suggestion and dispelled by persuasion. The characteristic of the secondary signs is that they are closely related to the primary phenomena."

The causes of hysteria may be divided into (*a*) the predisposing, such as hereditary predisposition to nervous disease, sex, age and national idiosyncrasy; and (*b*) the immediate, such as mental and physical exhaustion, fright and other emotional influences, pregnancy, the puerperal condition, diseases of the uterus and its appendages, and the depressing influence of injury or general disease. Perhaps, taken over all, hereditary predisposition to nerve-instability may be asserted as the most prolific cause. There is frequently direct inheritance, and cases of epilepsy and insanity or other form of nervous disease are rarely wanting when the family history is carefully enquired into. As regards age, the condition is apt to appear at the evolution periods of life—puberty, pregnancy and the climacteric—without any further assignable cause except that first spoken of. It is rare in young children, but very frequent in girls between the ages of fifteen and twenty-five, while it sometimes manifests itself in women at the menopause. It is much more common in the female than in the male—in the proportion of 20 to 1. Certain races are more liable to the disease than others; thus the Latin races are much more prone to hysteria than are those who come of a Teutonic stock, and in more aggravated and complex forms. In England it has been asserted that an undue proportion of cases occur among Jews. Occupation, or be it rather said want of occupation, is a prolific cause. This is noticeable more especially in the higher classes of society.

An hysterical attack may occur as an immediate sequel to an epileptic fit. If the patient suffers only from *petit mal* (see EPILEPSY), unaccompanied by true epileptic fits, the significance of the hysterical seizure, which is really a post-epileptic phenomenon, may remain unrecognized.

It is convenient to group the very varied symptoms of hysteria into paroxysmal and chronic. The popular term "hysterics" is applied to an explosion of emotionalism, generally the result of mental excitement, on which convulsive fits may supervene. The characters of these vary, and may closely resemble epilepsy. The hysterical fit is generally preceded by an aura or warning. This sometimes takes the form of a sensation as of a lump in the throat (*globus hystericus*). The patient may fall, but very rarely is injured in so doing. The eyes are often tightly closed, the body and limbs become rigid, and the back may become so arched that the patient rests on her heels and head (*opisthotonos*). This stage is usually followed by violent struggling movements. There is no loss of consciousness. The attack may last for half-an-hour or even longer. Hysterical fits in their fully-developed form are rarely seen in England, though common in France. In the chronic condition we find an extraordinary complexity of symptoms, both physical and mental. The physical symptoms are extremely diverse. There may be a paralysis of one or more limbs associated with rigidity, which may persist for weeks, months or years. In some cases, the patient is unable to walk; in others there are peculiarities of the gait quite unlike anything met with in organic disease. Perversions of sensation are usually present; a common instance is the sensation of a nail being driven through the vertex of the head (*clavus hystericus*). The region of the spine is a very frequent seat of hysterical pain. Loss of sensation (*anaesthesia*), of which the patient may be unaware, is of common occurrence. Very often this sensory loss is limited exactly to one-half of the body, including the leg, arm and face on that side (*hemianaesthesia*). Sensation to touch, pain, heat and cold, and electrical stimuli may have completely disappeared in the anaesthetic region. In other cases, the anaesthesia is relative or it may be partial, certain forms of sensation remaining intact. Anaesthesia is almost always accompanied by an inability to recognize the exact position of the affected limb when the eyes are closed. When hemianaesthesia is present, sight, hearing, taste and smell are usually impaired on that side of the body. Often there is loss of voice (hysterical aphonia). It is to such cases of hysterical paralysis and sensory disturbance that the wonderful cures effected by quacks and charlatans may be referred. The mental symptoms have not the same tendency to pass away suddenly. They may be spoken of as inter-paroxysmal and paroxysmal. The chief characteristics of the former are extreme emotionalism combined with obstructiveness, a desire to be an object of interest and a constant craving for sympathy which is often procured at an immense sacrifice of personal comfort. Obstructiveness is the invariable symptom. Hysteria may pass into absolute insanity.

The treatment of hysteria demands great tact and firmness on the part of the physician. The affection is a definite entity and has to be clearly distinguished from malingering, with which it is so often erroneously regarded as synonymous. Drugs are of little value. The moral treatment is all-important. In severe cases, removal from home surroundings and isolation, either in a hospital ward or nursing home, are essential, in order that full benefit may be derived from psychotherapeutic measures.

HYSTERON-PROTERON (Gr. ὕστερον, latter, and πρότερον, former), a figure of speech, in which the order of words or phrases is inverted, and that which should logically or naturally come last is put first, to secure emphasis for the principal idea; the classical example is Virgil's "*moriamur et in media arma ruamus*," "let us die and charge into the thick of the fight" (Aen. ii. 358). The term is also applied to any inversion in order of events, arguments, &c.

HYTHE, a market town and watering-place, one of the Cinque Ports, and a municipal and parliamentary borough of Kent, England, 67 m. S.E. by E. of London on a branch of the South Eastern & Chatham railway. Pop. (1901) 5557. It is beautifully situated at the foot of a steep hill near the eastern extremity of Romney Marsh, about half a mile from the sea, and consists principally of one long street running parallel with the shore, with which it is connected by a straight avenue of wych elms. On account of its fine situation and picturesque and interesting neighbourhood, it is a favourite watering-place. A sea-wall and parade extend eastward to Sandgate, a distance of 3 m. There is communication with Sandgate by means of a tramway along the front. On the slope of the hill above the town stands the fine church of St Leonard, partly Late Norman, with a very beautiful Early English chancel. The tower was rebuilt about 1750. In a vault under the chancel there is a collection of human skulls and bones supposed to be the remains of men killed in a battle near Hythe in 456. Lionel Lukin (1742–1834), inventor of the life-boat, is buried in the churchyard. Hythe possesses a guildhall founded in 1794 and two hospitals, that of St Bartholomew founded by Haimo, bishop of Rochester, in 1336, and that of St John (rebuilt in 1802), of still greater antiquity but unknown date, founded originally for the reception of lepers. A government school of musketry, in which instructors for the army are trained, was established in 1854, and has been extended since, and the Shorncliffe military camp is within 2½ m. of the town.

Lympne, which is now 3 m. inland, is thought to have been the original harbour which gave Hythe a place among the Cinque Ports. The course of the ancient estuary may be distinctly traced from here along the road to Hythe, the sea-sand lying on the surface and colouring the soil. Here are remains of a Roman fortress, and excavations have brought to light many remains of the Roman *Portus Lemanis*. Large portions of the fortress walls are standing. At the south-west corner is one of the circular towers which occurred along the line of wall. The site is now occupied by the fine old castellated mansion of Studfall castle, formerly a residence of the archdeacons of Canterbury. The name denotes a fallen place, and is not infrequently thus applied to ancient remains. The church at Lympne is Early English, with a Norman tower built by Archbishop Lanfranc, and Roman material may be traced in the walls. A short distance east is Shipway or Shepway Cross, where some of the great assemblies relating to the Cinque Ports were held. A mile north from Hythe is Saltwood Castle, of very ancient origin, but rebuilt in the time of Richard II. The castle was granted to the see of Canterbury in 1026, but escheated to the crown in the time of Henry II., when the murder of Thomas à Beckett is said to have been concerted here, and having been restored to the archbishops by King John remained a residence of theirs until the time of Henry VIII. It was restored as a residence in 1882. About 2 m. N.W. of Saltwood are remains of the fortified 14th-century manor-house of Westenhanger. It is quadrangular and surrounded by a moat, and of the nine towers (alternately square and round) by which the walls were defended, three remain.

The parliamentary borough of Hythe, which includes Folkestone, Sandgate and a number of neighbouring villages, returns one member. The town is governed by a mayor, 4 aldermen and 12 councillors. Area 2617 acres.

Hythe (Heda, Heya, Hethe, Hithe, *i.e.* landing-place) was known as a port in Saxon times, and was granted by Halfden, a Saxon thegn, to Christ Church, Canterbury. In the Domesday Survey the borough is entered among the archbishop's lands as appurtenant to his manor of Saltwood, and the bailiff of the town was appointed by the archbishop. Hythe was evidently a Cinque Port before the Conquest, as King John in 1205 confirmed the liberties, viz. freedom from toll, the right to be impleaded only at the Shepway court, &c., which the townsmen had under Edward the Confessor. The liberties of the Cinque Ports were confirmed in Magna Carta and later by Edward I. in a general charter, which was confirmed, often with additions, by subsequent kings down to James II. John's charter to Hythe was confirmed by Henry IV., Henry V. and Henry VI. These charters were granted to the Cinque Ports in return for the fifty-seven ships which they supplied for the royal service, of which five were contributed by Hythe. The ports were first represented in the parliament of 1365, to which they each sent four members.

Hythe was governed by twelve jurats until 1574, when it was incorporated by Elizabeth under the title of the mayor, jurats and commonalty of Hythe; a fair for the sale of fish, &c., was also granted, to be held on the feast of St Peter and St Paul. As the sea gradually retreated from Hythe and the harbour became choked up with sand, the town suffered the fate of other places near it, and lost its old importance.

I the ninth letter of the English and Latin alphabet, the tenth in the Greek and Phoenician, because in these the symbol Teth (the Greek θ) preceded it. Teth was not included in the Latin alphabet because that language had no sound corresponding to the Greek θ, but the symbol was metamorphosed and utilized as the numeral C = 100, which took this form through the influence of the initial letter of the Latin *centum*. The name of I in the Phoenician alphabet was *Yōd*. Though in form it seems the simplest of letters it was originally much more complex. In Phoenician it takes the form 𐤉, which is found also in the earliest Syriac and Palestinian inscriptions with little modification. Ultimately in Hebrew it became reduced to a very small symbol, whence comes its use as a term of contempt for things of no importance as in "not one *jot* or tittle" (Matthew v. 18). The name passed from Phoenician to Greek, and thence to the Latin of the vulgate as *iōta*, and from the Latin the English word is derived. Amongst the Greeks of Asia it appears only as the simple upright I, but in some of the oldest alphabets elsewhere, as Crete, Thera, Attica, Achaia and its colonies in lower Italy, it takes the form ∫ or S, while at Corinth and Corcyra it appears first in a form closely resembling the later Greek *sigma* Σ. It had originally no cross-stroke at top and bottom, I being not *i* but *z*. The Phoenician alphabet having no vowel symbols, the value of *yōd* was that of the English *y*. In Greek, where the consonant sound had disappeared or been converted into *h*, I is regularly used as a vowel. Occasionally, as in Pamphylian, it is used dialectically as a glide between *i* and another vowel, as in the proper name Δαμάτριιυς. In Latin I was used alike for both vowel and consonant, as in *iugum* (yoke). The sound represented by it was approximately that still assigned to *i* on the continent. Neither Greek nor Latin made any distinction in writing between short and long *i*, though in the Latin of the Empire the long sound was occasionally represented by a longer form of the symbol I. The dot over the *i* begins in the 5th or 6th century A.D. In pronunciation the English short *i* is a more open sound than that of most languages, and does not correspond to the Greek and Latin sound. Nor are the English short and long *i* of the same quality. The short *i* in Sweet's terminology is a high-front-wide vowel, the long *i*, in English often spelt *ee* in words like *seed*, is diphthonged, beginning like the short vowel but becoming higher as it proceeds. The Latin short *i*, however, in final syllables was open and ultimately became *e*, *e.g.* in the neuter of *i*-stems as *utile* from *utili-s*. Medially both the short and the long sounds are very common in syllables which were originally unaccented, because in such positions many other sounds passed into *i*: *officio* but *facio*, *redimo* but *emo*, *quidlibet* but *lubet* (*libet* is later); *collīdo* but *laedo*, *fīdo* from an older *feido*, *istis* (dative plural) from an earlier *istois*. (P. Gi.)

IAMBIC, the term employed in prosody to denote a succession of verses, each consisting of a foot or metre called an iambus (ἴαμβος), formed of two syllables, of which the first is short and the second long (⏑ –). After the dactylic hexameter, the iambic trimeter was the most popular metre of ancient Greece. Archilochus is said to have been the inventor of this iambic verse, the τρίμετρος consisting of three iambic feet. In the Greek tragedians an iambic line is formed of six feet arranged in obedience to the following scheme:—

⏑ –	⏑ –	⏑ –	⏑ –	⏑ –	⏑ –
⏑ ⏑ ⏑	⏑ ⏑ ⏑	⏑ ⏑ ⏑	⏑ ⏑ ⏑	⏑ ⏑ ⏑	
– –		– –		– –	
– ⏑ ⏑		– ⏑ ⏑			
⏑ ⏑ –					

Much of the beauty of the verse depends on the caesura, which is usually in the middle of the third foot, and far less frequently in the middle of the fourth. The English language runs more naturally in the iambic metre than in any other. The normal blank verse in English is founded upon an iambic basis, and Milton's line—

And swims | or sinks | or wades | or creeps | or flies | —

exhibits it in its primitive form. The ordinary alexandrine of French literature is a hexapod iambic, but in all questions of quantity in modern prosody great care has to be exercised to recollect that all ascriptions of classic names to modern forms of rhymed or blank verse are merely approximate. The octosyllabic, or four-foot iambic metre, has found great favour in English verse founded on old romances. Decasyllabic iambic lines rhyming together form an "heroic" metre.

IAMBLICHUS (d. *c.* A.D. 330), the chief representative of Syrian Neoplatonism, is only imperfectly known to us in the events of his life and the details of his creed. We learn, however, from Suidas, and from his biographer Eunapius, that he was born at Chalcis in Coele-Syria, the scion of a rich and illustrious family, that he studied under Anatolius and afterwards under Porphyry, the pupil of Plotinus, that he himself gathered together a large number of disciples of different nations with whom he lived on terms of genial friendship, that he wrote "various philosophical books," and that he died during the reign of Constantine,—according to Fabricius, before A.D. 333. His residence (probably) at his native town of Chalcis was varied by a yearly visit with his pupils to the baths of Gadara. Of the books referred to by Suidas only a fraction has been preserved. His commentaries on Plato and Aristotle, and works on the Chaldaean theology and on the soul, are lost. For our knowledge of his system we are indebted partly to the fragments of these writings preserved by Stobaeus and others, and to the notices of his successors, especially Proclus, partly to his five extant books, the sections of a great work on the Pythagorean philosophy. Besides these, Proclus (412–485) seems to have ascribed to him[1] the authorship of the celebrated book *On the Egyptian Mysteries* (so-called), and although its differences in style and in some points of doctrine from the writings just mentioned make it improbable that the work was by Iamblichus himself, it certainly emanated from his school, and in its systematic attempt to give a speculative justification of the polytheistic cultus of the day, marks the turning-point in the history of thought at which Iamblichus stood.

As a speculative theory Neoplatonism (*q.v.*) had received its highest development from Plotinus. The modifications introduced by Iamblichus were the elaboration in greater detail of its formal divisions, the more systematic application of the Pythagorean number-symbolism, and chiefly, under the influence of Oriental systems, the thorough-going mythic interpretation of what the previous philosophy had still regarded as notional. It is on the last account, probably, that Iamblichus was looked upon with such extravagant veneration. As a philosopher he had learning indeed, but little originality. His aim was to give a philosophical rendering of the popular religion. By his contemporaries he was accredited with miraculous powers (which he, however, disclaimed), and by his followers in the decline of Greek philosophy, and his admirers on its revival in the 15th and 16th centuries, his name was scarcely mentioned without the epithet "divine" or "most divine," while, not content with the more modest eulogy of Eunapius that he was inferior to Porphyry only in style, the emperor Julian regarded him as not even second to Plato, and said that he would give all the gold of Lydia for one epistle of Iamblichus.

Theoretically, the philosophy of Plotinus was an attempt to harmonize the principles of the various Greek schools. At the head of his system he placed the transcendent incommunicable one (ἓν ἀμέθεκτον), whose first-begotten is intellect (νοῦς), from which proceeds soul (ψυχή), which in turn gives birth to φύσις, the

[1] Besides the anonymous testimony prefixed to an ancient MS. of Proclus, *De Myst.* viii. 3 seems to be quoted by the latter as Iamblichus's. Cf. Meiners, "Judicium de libro qui de Myst. Aeg. inscribitur," in *Comment. Soc. Reg. Sci. Gott.*, vol. iv., 1781, p. 77.

realm of nature. Immediately after the absolute one, Iamblichus introduced a second superexistent unity to stand between it and the many as the producer of intellect, and made the three succeeding moments of the development (intellect, soul and nature) undergo various modifications. He speaks of them as intellectual (*θεοὶ νοεροί*), supramundane (*ὑπερκόσμιοι*), and mundane gods (*ἐγκόσμιοι*). The first of these—which Plotinus represented under the three stages of (objective) being (*ὄν*), (subjective) life (*ζωή*), and (realized) intellect (*νοῦς*)—is distinguished by him into spheres of intelligible gods (*θεοὶ νοητοί*) and of intellectual gods (*θεοὶ νοεροί*), each subdivided into triads, the latter sphere being the place of ideas, the former of the archetypes of these ideas. Between these two worlds, at once separating and uniting them, some scholars think there was inserted by Iamblichus, as afterwards by Proclus, a third sphere partaking of the nature of both (*θεοὶ νοητοὶ καὶ νοεροί*). But this supposition depends on a merely conjectural emendation of the text. We read, however, that "in the intellectual hebdomad he assigned the third rank among the fathers to the Demiurge." The Demiurge, Zeus, or world-creating potency, is thus identified with the perfected *νοῦς*, the intellectual triad being increased to a hebdomad, probably (as Zeller supposes) through the subdivision of its first two members. As in Plotinus *νοῦς* produced nature by mediation of *ψυχή*, so here the intelligible gods are followed by a triad of psychic gods. The first of these is incommunicable and supramundane, while the other two seem to be mundane though rational. In the third class, or mundane gods (*θεοὶ ἐγκόσμιοι*), there is a still greater wealth of divinities, of various local position, function, and rank. We read of gods, angels, demons and heroes, of twelve heavenly gods whose number is increased to thirty-six or three hundred and sixty, and of seventy-two other gods proceeding from them, of twenty-one chiefs (*ἡγεμόνες*) and forty-two nature-gods (*θεοὶ γενεσιουργοί*), besides guardian divinities, of particular individuals and nations. The world is thus peopled by a crowd of superhuman beings influencing natural events, possessing and communicating knowledge of the future, and not inaccessible to prayers and offerings.

The whole of this complex theory is ruled by a mathematical formulism of triad, hebdomad, &c., while the first principle is identified with the monad, *νοῦς* with the dyad, and *ψυχή* with the triad, symbolic meanings being also assigned to the other numbers. "The theorems of mathematics," he says, "apply absolutely to all things," from things divine to original matter (*ὕλη*). But though he thus subjects all things to number, he holds elsewhere that numbers are independent existences, and occupy a middle place between the limited and unlimited.

Another difficulty of the system is the account given of nature. It is said to be "bound by the indissoluble chains of necessity which men call fate," as distinguished from divine things which are not subject to fate. Yet, being itself the result of higher powers becoming corporeal, a continual stream of elevating influence flows from them to it, interfering with its necessary laws and turning to good ends the imperfect and evil. Of evil no satisfactory account is given; it is said to have been generated accidentally.

In his doctrine of man Iamblichus retains for the soul the middle place between intellect and nature which it occupies in the universal order. He rejects the passionless and purely intellectual character ascribed to the human soul by Plotinus, distinguishing it sharply both from those above and those below it. He maintains that it moves between the higher and lower spheres, that it descends by a necessary law (not solely for trial or punishment) into the body, and, passing perhaps from one human body to another, returns again to the supersensible. This return is effected by the virtuous activities which the soul performs through its own power of free will, and by the assistance of the gods. These virtues were classified by Porphyry as political, purifying (*καθαρτικαί*), theoretical, and paradigmatic; and to these Iamblichus adds a fifth class of priestly virtues (*ἱερατικαὶ ἀρεταί*), in which the divinest part of the soul raises itself above intellect to absolute being.

Iamblichus does not seem ever to have attained to that ecstatic communion with and absorption in deity which was the aim of earlier Neoplatonism, and which Plotinus enjoyed four times in his life, Porphyry once. Indeed his tendency was not so much to raise man to God as to bring the gods down to men—a tendency shown still more plainly in the "Answer of Abamon the master to Porphyry's letter to Anebo and solutions of the doubts therein expressed," afterwards entitled the *Liber de mysteriis*, and ascribed to Iamblichus.

In answer to questions raised and doubts expressed by Porphyry, the writer of this treatise appeals to the innate idea all men have of the gods as testifying to the existence of divinities countless in number and various in rank (to the correct arrangement of which he, like Iamblichus, attaches the greatest importance). He holds with the latter that above all principles of being and intelligence stands the absolute one, from whom the first god and king spontaneously proceeds; while after these follow the ethereal, empyrean, and heavenly gods, and the various orders of archangels, angels, demons, and heroes distinguished in nature, power, and activity, and in greater profusion than even the imagination of Iamblichus had conceived. He says that all the gods are good (though he in another place admits the existence of evil demons who must be propitiated), and traces the source of evil to matter; rebuts the objection that their answering prayer implies passivity on the part of gods or demons; defends divination, soothsaying, and theurgic practices as manifestations of the divine activity; describes the appearances of the different sorts of divinities; discusses the various kinds of sacrifice, which he says must be suitable to the different natures of the gods, material and immaterial, and to the double condition of the sacrificer as bound to the body or free from it (differing thus in his psychology from Iamblichus); and, in conclusion, states that the only way to happiness is through knowledge of and union with the gods, and that theurgic practices alone prepare the mind for this union—again going beyond his master, who held assiduous contemplation of divine things to be sufficient. It is the passionless nature of the soul which permits it to be thus united to divine beings,—knowledge of this mystic union and of the worship associated with it having been derived from the Egyptian priests, who learnt it from Hermes.

On one point only does the author of the *De mysteriis* seem not to go so far as Iamblichus in thus making philosophy subservient to priestcraft. He condemns as folly and impiety the worship of images of the gods, though his master held that these *simulacra* were filled with divine power, whether made by the hand of man or (as he believed) fallen from heaven. But images could easily be dispensed with from the point of view of the writer, who not only held that all things were full of gods (*πάντα πλήρη θεῶν*, as Thales said), but thought that each man had a special divinity of his own—an *ἴδιος δαίμων*—as his guard and companion.

The following are the extant works of Iamblichus: (1) *On the Pythagorean* (*Life* Περὶ τοῦ Πυθαγορικοῦ βίου), ed. T. Kiessling (1815), A. Nauck (St Petersburg, 1884); for a discussion of the authorities used see E. Rohde in *Rheinisches Museum*, xxvi., xxvii. (1871, 1872); Eng. trans. by Thomas Taylor (1818). (2) The *Exhortation to Philosophy* (Λόγος προτρεπτικὸς εἰς φιλοσοφίαν), ed. T. Kiessling (1813); H. Piselli (1888). (3) The treatise *On the General Science of Mathematics* (Περὶ τῆς κοινῆς μαθηματικῆς ἐπιστήμης), ed. J. G. Friis (Copenhagen, 1790), N. Festa (Leipzig, 1891). (4) The book *On the Arithmetic of Nicomachus* (Περὶ τῆς Νικομάχου ἀριθμητικῆς εἰσαγωγῆς), along with fragments on fate (Περὶ εἱμαρμένης) and prayer (Περὶ εὐχῆς), ed. S. Tennulius (1688), the *Arithmetic* by H. Pistelli (1894). (5) The *Theological Principles of Arithmetic* (Θεολογούμενα τῆς ἀριθμητικῆς)—the seventh book of the series—by F. Ast (Leipzig, 1817). Two lost books, treating of the physical and ethical signification of numbers, stood fifth and sixth, while books on music, geometry and astronomy followed. The emperor Julian had a great admiration for Iamblichus, whom he considered "intellectually not inferior to Plato"; but the *Letters to Iamblicus the Philosopher* which bear his name are now generally considered spurious.

The so-called *Liber de mysteriis* was first edited, with Latin translation and notes, by T. Gale (Oxford, 1678), and more recently by G. Parthey (Berlin, 1857); Eng. trans. by Thomas Taylor (1821).

There is a monograph on Iamblichus by G. E. Hebenstreit (*De Iamblichi, philosophi Syri, doctrina*, Leipzig, 1764), and one of the *De myst.* by Harless (*Das Buch v. d. ägypt. Myst.*, Munich, 1858). The best accounts of Iamblichus are those of Zeller, *Phil. d. Griechen*, iii. 2, pp. 613 sq., 2nd ed.; E. Vacherot, *Hist. de l'école d'Alexandrie* (1846), ii. 57 sq.; J. Simon, *Hist. de l'école d'Alexandrie* (1845); A. E. Chaignet, *Histoire de la psychologie des Grecs* (Paris, 1893) v. 67-108; T. Whittaker, *The Neo-Platonists* (Cambridge, 1901). (W. R. So.)

IAMBLICHUS, of Syria, the earliest of the Greek romance writers, flourished in the 2nd century A.D. He was the author of Βαβυλωνιακά, the loves of Rhodanes and Sinonis, of which an epitome is preserved in Photius (cod. 94). Garmus, a legendary king of Babylon, forces Sinonis to marry him and throws Rhodanes into prison. The lovers manage to escape, and after many singular adventures, in which magic plays a considerable part, Garmus is overthrown by Rhodanes, who becomes king of Babylon. According to Suidas, Iamblichus was a freedman, and a scholiast's note on Photius further informs us that he was a native Syrian (not descended from Greek settlers); that he borrowed the material for his romance from a love story told him by his Babylonian tutor, and that he subsequently applied himself with great success to the study of Greek. A MS. of the original in the library of the Escorial is said to have been destroyed by fire in 1670. Only a few fragments have been preserved, in addition to Photius's epitome.

See *Scriptores erotici*, ed. A. Hirschig (1856) and R. Hercher (1858); A. Mai, *Scriptorum veterum nova collectio*, ii.; E. Rohde, *Der griechische Roman* (1900).

IANNINA (*i.e.* "the city of St John"; Gr. *Ioannina*; Turk *Yaniá*; also written Janina, Jannina, and, according to its Albanian pronunciation, Yanina), the capital of the vilayet of Iannina, Albania, European Turkey. Pop. (1905) about 22,000. The largest ethnical groups in the population are the Albanian and Greek; the purest form of colloquial Greek is spoken here among the wealthy and highly educated merchant families. The position of Iannina is strikingly picturesque. At the foot of the grey limestone mass of Mount Mitzekeli (1500 ft.), which forms part of the fine range of hills running north from the Gulf of Arta, there lies a valley (the *Hellopia* of antiquity) partly occupied by a lake; and the city is built on the slopes of a slight eminence, stretching down to the western shore. It has greatly declined from the state of barbaric prosperity which it enjoyed from 1788 to 1822, when it was the seat of Ali Pasha (*q.v.*), and was estimated to have from 30,000 to 50,000 inhabitants. The fortress—Demir Kule or Iron Castle, which, like the principal seraglio, was built on a promontory jutting into the lake—is now in ruins. But the city is the seat of a Greek archbishop, and still possesses many mosques and churches, besides synagogues, a Greek college (gymnasium), a library and a hospital. Sayades (opposite Corfu) and Arta are the places through which it receives its imports. The rich gold and silver embroidery for which the city has long been famous is still one of the notable articles in its bazaar; but the commercial importance of Iannina has notably declined since the cession of Arta and Thessaly to Greece in 1881. Iannina had previously been one of the chief centres of the Thessalian grain trade; it now exports little except cheese, hides, bitumen and sheepskins to the annual value of about £120,000; the imports, which supply only the local demand for provisions, textile goods, hardware, &c., are worth about double that sum.

The lake of Iannina (perhaps to be identified with the Pambotus or Pambotis of antiquity) is 6 m. long, and has an area of 24 sq. m., with an extreme depth of less than 35 ft. In time of flood it is united with the smaller lake of Labchistas to the north. There are no affluents of any considerable size, and the only outlets are underground passages or *katavothra* extending for many miles through the calcareous rocks.

The theory supported by W. M. Leake (*Northern Greece*, London, 1835) that the citadel of Iannina is to be identified with Dodona, is now generally abandoned in favour of the claims of a more southern site. As Anna Comnena, in describing the capture of the town (τὰ Ἰοάννινα) by Bohemond in 1082, speaks of the walls as being dilapidated, it may be supposed that the place existed before the 11th century. It is mentioned from time to time in the Byzantine annals, and on the establishment of the lordship of Epirus by Michael Angelus Comnenus Ducas, it became his capital. In the middle ages it was successively attacked by Serbs, Macedonians and Albanians; but it was in possession of the successors of Michael when the forces of the Sultan Murad appeared before it in 1430 (cf. Hahn, *Alban. Studien*, Jena [1854], pp. 319–322). Since 1431 it has continued under Turkish rule.

Descriptions of Iannina will be found in Holland's *Travels* (1815); Hughes, *Travels in Greece*, &c. (1830); H. F. Tozer, *Researches in the Highlands of Turkey* (London, 1869). See also ALBANIA and the authorities there cited.

IAPETUS, in Greek mythology, son of Uranus and Gaea, one of the Titans, father of Atlas, Prometheus, Epimetheus and Menoetius, the personifications of certain human qualities (Hesiod, *Theog.* 507). As a punishment for having revolted against Zeus, he was imprisoned in Tartarus (Homer, *Iliad*, viii. 479) or underneath the island of Inarime off the coast of Campania (Silius Italicus xii. 148). Hyginus makes him the son of Tartarus and Gaea, and one of the giants. Iapetus was considered the original ancestor of the human race, as the father of Prometheus and grandfather of Deucalion. The name is probably identical with Japhet (Japheth), and the son of Noah in the Greek legend of the flood becomes the ancestor of (Noah) Deucalion. Iapetus as the representative of an obsolete order of things is described as warring against the new order under Zeus, and is naturally relegated to Tartarus.

See F. G. Welcker, *Griechische Götterlehre*, i. (1857); C. H. Völcker, *Die Mythologie des Iapetischen Geschlechtes* (1824); M. Mayer, *Giganten und Titanen* (1887).

IAPYDES, or IAPODES, one of the three chief peoples of Roman Illyria. They occupied the interior of the country on the north between the Arsia (Arsa) and Tedanius (perhaps the Zermanja), which separated them from the Liburnians. Their territory formed part of the modern Croatia. They are described by Strabo as a mixed race of Celts and Illyrians, who used Celtic weapons, tattooed themselves, and lived chiefly on spelt and millet. They were a warlike race, addicted to plundering expeditions. In 129 B.C. C. Sempronius Tuditanus celebrated a triumph over them, and in 34 B.C. they were finally crushed by Augustus. They appear to have had a *foedus* with Rome, but subsequently rebelled.

See Strabo iv. 207, vii. 313-315; Dio Cassius xlix. 35; Appian, *Illyrica*, 10, 14, 16; Livy, *Epit.* lix. 131; Tibullus iv. 1. 108; Cicero, *Pro Balbo*, 14.

IATROCHEMISTRY (coined from Gr. ἰατρός, a physician, and "chemistry"), a stage in the history of chemistry, during which the object of this science was held to be "not to make gold but to prepare medicines." This doctrine dominated chemical thought during the 16th century, its foremost supporters being Paracelsus, van Helmont and de la Boë Sylvius. But it gave way to the new definition formulated by Boyle, viz. that the proper domain of chemistry was "to determine the composition of substances." (See CHEMISTRY: I. *History*; MEDICINE.)

IAZYGES, a tribe of Sarmatians first heard of on the Maeotis, where they were among the allies of Mithradates the Great. Moving westward across Scythia, and hence called Metanastae, they were on the lower Danube by the time of Ovid, and about A.D. 50 occupied the plains east of the Theiss. Here, under the general name of Sarmatae, they were a perpetual trouble to the Roman province of Dacia. They were divided into freemen and serfs (*Sarmatae Limigantes*), the latter of whom had a different manner of life and were probably an older settled population enslaved by nomad masters. They rose against them in A.D. 334, but were repressed by foreign aid. Nothing is heard of Iazyges or Sarmatae after the Hunnish invasions. Graves at Keszthely and elsewhere in the Theiss valley, shown by their contents to belong to nomads of the first centuries A.D., are referred to the Iazyges. (E. H. M.)

IBADAN, a town of British West Africa, in Yorubaland, Southern Nigeria, 123 m. by rail N.E. of Lagos, and about 50 m. N.E. of Abeokuta. Pop. (1910 estimated at 150,000. The town occupies the slope of a hill, and stretches into the valley through which the river Ona flows. It is enclosed by mud walls, which have a circuit of 18 m., and is encompassed by cultivated land 5 or 6 m. in breadth. The native houses are all low, thatched structures, enclosing a square court, and the only break in the mud wall is the door. There are numerous mosques, *orishas* (idol-houses) and open spaces shaded with trees. There are a few buildings in the European style. Most of the inhabitants are engaged in agriculture; but a great variety of handicrafts is also carried on. Ibadan is the capital of one of the Yoruba states and enjoys a large measure of autonomy. Nominally the state is subject to the *alafin* (ruler) of Oyo; but it is virtually independent. The administration is in the hands of two chiefs, a civil and a military, the *bale* and the *balogun*; these together form the highest court of appeal. There is also an *iyaloda* or mother of the town, to whom are submitted all the disputes of the women. Ibadan long had a feud with Abeokuta, but on the establishment of the British protectorate the intertribal wars were stopped. In 1862 the people of Ibadan destroyed Ijaya, a neighbouring town of 60,000 inhabitants. A British resident and a detachment of Hausa troops are stationed at Ibadan.

See also YORUBAS, ABEOKUTA and LAGOS.

IBAGUÉ, or SAN BONIFACIO DE IBAGUÉ, a city of Colombia, and capital of the department of Tolima, about 60 m. W. of Bogotá and 18 m. N.W. of the Nevado de Tolima. Pop. (1900, estimate) 13,000. Ibagué is built on a beautiful plain between the Chipalo and Combeima, small affluents of the Cuello, a western tributary of the Magdalena. Its elevation, 4300 ft. above the sea, gives it a mild, subtropical climate. The plain and the neighbouring valleys produce cacao, tobacco, rice and sugar-cane. There are two thermal springs in the vicinity, and undeveloped mines of sulphur and silver. The city has an endowed college. It is an important commercial centre, being on the road which crosses the Quindio pass, or *paramo*, into the Cauca valley. Ibagué was founded in 1550 and was the capital of the republic for a short time in 1854.

IBARRA, a city of Ecuador and capital of the province of Imbabura, about 50 m. N.N.E. of Quito, on a small fertile plain at the northern foot of Imbabura volcano, 7300 ft. above sea-level. Pop. (1900, estimate) 5000. It stands on the left bank of the Tahuando, a small stream whose waters flow north and west to the Pacific through the Mira, and is separated from the higher plateau of Quito by an elevated transverse ridge of which the Imbabura and Mojanda volcanoes form a part. The surrounding country is mountainous, the valleys being very fertile. Ibarra itself has a mild, humid climate, and is set in the midst of orchards and gardens. It is the see of a bishop and has a large number of churches and convents, and many substantial residences. Ibarra has manufactures of cotton and woollen fabrics, hats, sandals (*alpargates*), sacks and rope from *cabulla* fibre, laces, sugar and various kinds of distilled spirits and cordials made from the sugar-cane grown in the vicinity. Mules are bred for the Colombian markets of Pasto and Popayan. Ibarra was founded in 1597 by Alvaro de Ibarra, the president of Quito. It has suffered from the eruptions of Imbabura, and more severely from earthquakes, that of 1859 causing great damage to its public buildings, and the greater one of the 16th of August 1868 almost completely destroyed the town and killed a large number of its inhabitants. The village of Carranqui, 1¼ m. from Ibarra, is the birthplace of Atahualpa, the Inca sovereign executed by Pizarro, and close by is the small lake called Yaguarcocha where the army of Huaynacapac, the father of Atahualpa, inflicted a bloody defeat on the Carranquis. Another aboriginal battle-field is that of Hatuntaqui, near Ibarra, where Huaynacapac won a decisive victory and added the greater part of Ecuador to his realm. The whole region is full of *lolas*, or Indian burial mounds.

IBERIANS (Iberi, Ἴβηρες), an ancient people inhabiting parts of the Spanish peninsula. Their ethnic affinities are not known, and our knowledge of their history is comparatively slight. It is almost impossible to make any statement in regard to them which will meet with general agreement. At the same time, the general lines of Iberian controversy are clear enough. The principal sources of information about the Iberians are (1) historical, (2) numismatic, (3) linguistic, (4) anthropological.

1. *Historical.*—The name seems to have been applied by the earlier Greek navigators to the peoples who inhabited the eastern coast of Spain; probably it originally meant those who dwelt by the river Iberus (mod. *Ebro*). It is possible (Boudard, *Études sur l'alphabet ibérien* (Paris, 1852) that the river-name itself represents the Basque phrase *ibay-erri* "the country of the river." On the other hand, even in older Greek usage (as in Thuc. vi. 1) the term Iberia is said to have embraced the country as far east as the Rhone (see Herodorus of Heraclea, *Fragm. Hist. Gr.* ii. 34), and by the time of Strabo it was the common Greek name for the Spanish peninsula. Iberians thus meant sometimes the population of the peninsula in general and sometimes, it would appear, the peoples of some definite race (γένος) which formed one element in that population. Of the tribal distribution of this race, of its linguistic, social and political characteristics, and of the history of its relation to the other peoples of Spain, we have only the most general, fragmentary and contradictory accounts. On the whole, the historical evidence indicates that in Spain, when it first became known to the Greeks and Romans there existed many separate and variously civilized tribes connected by at least apparent identity of race, and by similarity (but not identity) of language, and sufficiently distinguished by their general characteristics from Phoenicians, Romans and Celts. The statement of Diodorus Siculus that the mingling of these Iberians with the immigrant Celts gave rise to the Celtiberians is in itself probable. Varro and Dionysius Afer proposed to identify the Iberians of Spain with the Iberians of the Caucasus, the one regarding the eastern, and other the western, settlements as the earlier.

2. *Numismatic.*—Knowledge of ancient Iberian language and history is mainly derived from a variety of coins, found widely distributed in the peninsula,[1] and also in the neighbourhood of Narbonne. They are inscribed in an alphabet which has many points of similarity with the western Greek alphabets, and some with the Punic alphabet; but which seems to retain a few characters from an older script akin to those of Minoan Crete and Roman Libya.[2] The same Iberian alphabet is found also rarely in inscriptions. The coinage began before the Roman conquest was completed; the monetary system resembles that of the Roman republic, with values analogous to *denarii* and *quinarii.* The coin inscriptions usually give only the name of the town, *e.g.* PLPLIS (Bilbilis), KLAQRIQS (Calagurris), SEQBRICS (Segobriga), TMANIAV (Dumania). The types show late Greek and perhaps also late Punic influence, but approximate later to Roman models. The commonest reverse type, a charging horseman, reappears on the Roman coins of Bilbilis, Osca, Segobriga and other places. Another common type is one man leading two horses or brandishing a sword or a bow. The obverse has usually a male head, sometimes inscribed with what appears to be a native name.

3. *Linguistic.*—The survival of the non-Aryan language among the Basques around the west Pyrenees has suggested the attempt to interpret by its means a large class of similar-sounding place-names of ancient Spain, some of which are authenticated by their occurrence on the inscribed coins, and to link it with other traces of non-Aryan speech round the shores of the Western Mediterranean and on the Atlantic seaboard of Europe. This phase of Iberian theory opens with K. W. Humboldt (*Prüfung der Untersuchungen über die Urbewohner Hispaniens vermittelst der waskischen Sprache*, Berlin, 1821),

[1] For the prehistoric civilization of the peninsula as a whole see SPAIN.

Halbinsel* (Vienna, 1870); W. M. Flinders Petrie, *Journ. Anthr. Inst.* xxix. (1899) 204, and above all E. Hübner, *Monumenta linguae Ibericae.*

who contended that there existed once a single great Iberian people, speaking a distinct language of their own; that an essentially "Iberian" population was to be found in Sicily, Sardinia and Corsica, in southern France, and even in the British Isles; and that the Basques of the present day were remnants of this race, which had elsewhere been expelled or absorbed. This last was the central and the seminal idea of the work, and it has been the point round which the battle of scholarship has mainly raged. The principal evidence which Humboldt adduced in its support was the possibility of explaining a vast number of the ancient topographical names of Spain, and of other asserted Iberian districts, by the forms and significations of Basque. In reply, Graslin (*De l'Ibérie*, Paris, 1839), maintained that the name Iberia was nothing but a Greek misnomer of Spain, and that there was no proof that the Basque people had ever occupied a wider area than at present; and Bladé (*Origine des Basques*, Paris, 1869) took the same line of argument, holding that Iberia is a purely geographical term, that there was no proper Iberian race, that the Basques were always shut in by alien races, that their affinity is still to seek, and that the whole Basque-Iberian theory is a figment. His main contention has met with some acceptance,[1] but the great current of ethnographical speculation still flows in the direction indicated by Humboldt.

4. *Anthropological.*—Humboldt's "Iberian theory" depended partly on linguistic comparisons, but partly on his observation of widespread similarity of physical type among the population of south-western Europe. Since his time the anthropological researches of Broca, Thurnam and Davis, Huxley, Busk, Beddoe, Virchow, Tubino and others have proved the existence in Europe, from Neolithic times, of a race, small of stature, with long or oval skulls, and accustomed to bury their dead in tombs. Their remains have been found in Belgium and France, in Britain, Germany and Denmark, as well as in Spain; and they bear a close resemblance to a type which is common among the Basques as well as all over the Iberian peninsula. This Neolithic race has consequently been nicknamed "Iberians," and it is now common to speak of the "Iberian" ancestry of the people of Britain, recognizing the racial characteristics of "Iberians" in the "small swarthy Welshman," the "small dark Highlander," and the "Black Celts to the west of the Shannon," as well as in the typical inhabitants of Aquitania and Brittany.[2] Later investigators went further. M. d'Arbois de Jubainville, for example (*Les Premiers habitants de l'Europe*, Paris, 1877), maintained that besides possessing Spain, Gaul, Italy and the British Isles, "Iberian" peoples penetrated into the Balkan peninsula, and occupied a part of northern Africa, Corsica and Sardinia; and it is now generally accepted that a race with fairly uniform characteristics was at one time in possession of the south of France (or at least of Aquitania), the whole of Spain from the Pyrenees to the straits, the Canary Islands (the Guanches) a part of northern Africa and Corsica. Whether this type is more conveniently designated by the word *Iberian*, or by some other name ("Eur-african," "Mediterranean," &c.) is a matter of comparative indifference, provided that there is no misunderstanding as to the steps by which the term *Iberian* attained its meaning in modern anthropology.

[1] W. van Eys, for example, "La Langue ibérienne et la langue basque," in *Revue de linguistique*, goes against Humboldt; but Prince Napoleon and to a considerable extent A. Luchaire maintain the justice of his method and the value of many of his results. See Luchaire, *Les Origines linguistiques de l'Aquitaine* (Paris, 1877).

[2] Compare the interesting résumé of the whole question in Boyd Dawkins's *Early Man in Britain* (London, 1880).

IBEX, one of the names of the Alpine wild goat, otherwise known as the steinbok and bouquetin, and scientifically as *Capra ibex*. Formerly the ibex was common on the mountain-ranges of Germany, Switzerland and Tirol, but is now confined to the Alps which separate Valais from Piedmont, and to the lofty peaks of Savoy, where its existence is mainly due to game-laws. The ibex is a handsome animal, measuring about 4½ ft. in length and standing about 40 in. at the shoulder. The skin is covered in summer with a short fur of an ashy-grey colour, and in winter with much longer yellowish-brown hair concealing a dense fur beneath. The horns of the male rise from the crest of the skull, and after bending gradually backwards terminate in smooth tips; the front surface of the remainder carrying bold transverse ridges or knots. About 1 yd. is the maximum recorded length of ibex-horns. The fact that the fore-legs are somewhat shorter than those behind enables the ibex to ascend mountain slopes with more facility than it can descend, while its hoofs are as hard as steel, rough underneath and when walking over a flat surface capable of being spread out. These, together with its powerful sinews, enable it to take prodigious leaps, to balance itself on the smallest foothold and to scale almost perpendicular rocks. Ibex live habitually at a greater height than chamois or any other Alpine mammals, their vertical limit being the line of perpetual snow. There they rest in sunny nooks during the day, descending at night to the highest woods to graze. Ibex are gregarious, feeding in herds of ten to fifteen individuals; but the old males generally live apart from, and usually at greater elevations than, the females and young. They utter a sharp whistling sound not unlike that of the chamois, but when greatly irritated or frightened make a peculiar snorting noise. The period of gestation in the female is ninety days, after which she produces—usually at the end of June—a single young one which is able at once to follow its mother. Kids when caught young and fed on goat's milk can be readily tamed; and in the 16th century young tamed ibex were frequently driven to the mountains along with the goats, in whose company they would afterwards return. Even wild ibex have been known to stray among the herds of goats, although they shun the society of chamois. Its flesh is said to resemble mutton, but has a flavour of game.

By naturalists the name "ibex" has been extended to embrace all the kindred species of wild goats, while by sportsmen it is used in a still more elastic sense, to include not only the true wild goat (known in India as the Sind ibex) but even the short-horned *Hemitragus hylocrius* of the Nilgiris. Dealing only with species zoologically known as ibex, the one nearest akin to the European kind is the Asiatic or Siberian ibex (*Capra sibirica*), which, with several local phases, extends from the northern side of Kashmir over an enormous area in Central Asia. These ibex, especially the race from the Thian Shan, are incomparably finer than the European species, their bold knotted horns sometimes attaining a length of close on 60 in. The Arabian, or Nubian, ibex (*C. nubiana*) is characterized by the more slender type of hôrn, in which the front edge is much narrower; while the Simien ibex (*C. vali*) of Central Abyssinia is a very large and dark-coloured animal, with the horns black instead of brownish, and bearing only slightly marked front ridges. The Caucasian ibex (*C. caucasica*), or tur, is a wholly fox-coloured animal, in which the horns are still flatter in front, and thus depart yet further from the ibex type. In the Spanish ibex (*C. pyrenaica*) the horns are flattened, with ill-defined knobs, and a spiral twist. (SEE GOAT.) (W. H. F.; R. L.*)

The Ibex (*Capra ibex*).

IBIS, one of the sacred birds of the ancient Egyptians. James Bruce identified this bird with the *Abu-Hannes* or "Father John" of the Abyssinians, and in 1790 it received from Latham (*Index ornithologicus*, p. 706) the name of *Tantalus aethiopicus*. This determination was placed beyond question by Cuvier (*Ann. du Muséum*, iv. 116-135) and Savigny (*Hist. nat. et mythol. de l'ibis*) in 1805. They, however, removed it from the Linnaean genus *Tantalus* and, Lacépède having some years before founded a genus *Ibis*, it was transferred thither, and is now generally known as *I. aethiopica*, though some speak of it as *I. religiosa*. No attempt can here be made to treat the ibis from a mythological or antiquarian point of view. Savigny's memoir contains a great deal of matter on the subject. Wilkinson (*Ancient Egyptians*, ser. 2, vol. ii. pp. 217-224) added some of the results of later research, and Renouf in his *Hibbert Lectures* explains the origin of the myth.

The ibis is chiefly an inhabitant of the Nile basin from Dongola southward, as well as of Kordofan and Sennar; whence about midsummer it moves northwards to Egypt.[1] In Lower Egypt it bears the name of *Abu-mengel*, or "father of the sickle," from the form of its bill, but it does not stay long in that country, disappearing when the Nile has subsided. Hence most travellers have failed to meet with it there[2] (since their acquaintance with the birds of Egypt is limited to those which frequent the country in winter), and writers have denied generally to this species a place in its modern fauna (cf. Shelley, *Birds of Egypt*, p. 261). However, in 1864, von Heuglin (*Journ. für Ornithologie*, 1865, p. 100) saw a young bird which had been shot in the Delta, and E. C. Taylor (*Ibis*, 1878, p. 372) saw an adult which had been killed near Lake Menzal in 1877. The story told to Herodotus of its destroying snakes is, according to Savigny, devoid of truth, but Cuvier states that he discovered partly digested remains of a snake in the stomach of a mummied ibis.

The ibis is somewhat larger than a curlew, *Numenius arquata*, which bird it resembles, with a much stouter bill and stouter legs. The head and greater part of the neck are bare and black. The plumage is white, except the primaries, which are black, and a black plume, formed by the secondaries, tertials and lower scapulars, and richly glossed with bronze, blue and green, which curves gracefully over the hind-quarters. The bill and feet are also black. The young lack the ornamental plume, and in them the head and neck are clothed with short black feathers, while the bill is yellow. The nest is placed in bushes or high trees, the bird generally building in companies, and in the middle of August von Heuglin (*Orn. Nord-Ost-Afrikas*, p. 1138) found that it had from two to four young or much incubated eggs.[3] These are of a dingy white, splashed, spotted and speckled with reddish-brown.

Congeneric with the typical ibis are two or three other species, the *I. melanocephala* of India, the *I. molucca* or *I. strictipennis*, of Australia, and the *I. bernieri* of Madagascar, all of which closely resemble *I. aethiopica*; while many other forms not very far removed from it, though placed by authors in distinct genera,[4] are known. Among these are several beautiful species such as the Japanese *Geronticus nippon*, the *Lophotibis cristata* of Madagascar, and the scarlet ibis,[5] *Eudocimus ruber*, of America. The glossy ibis, *Plegadis falcinellus*, found throughout the West Indies, Central and the south-eastern part of North America, as well as in many parts of Europe (whence it not unfrequently strays to the British Islands), Africa, Asia and Australia. This bird, believed to be the second kind of ibis spoken of by Herodotus, is rather smaller than the sacred ibis, and mostly of a dark chestnut colour with brilliant green and purple reflections on the upper parts, exhibiting, however, when young none of the rufous hue. This species lays eggs of a deep sea-green colour, having wholly the character of heron's eggs, and it often breeds in company with herons, while the eggs of all other ibises whose eggs are known resemble those of the sacred ibis. Though ibises resemble the curlews externally, there is no affinity between them. The *Ibididae* are more nearly related to the storks, *Ciconiidae*, and still more to the spoonbills, *Plataleidae*, with which latter many systematists consider them to form one group, the *Hemiglottides* of Nitzsch. Together these groups form the sub-order *Ciconiae* of the order *Ciconiiformes*. The true ibises are also to be clearly separated from the wood-ibises, *Tantalidae*, of which there are four or five species, by several not unimportant structural characters. Fossil remains of a true

[1] It has been said to occur occasionally in Europe (Greece and southern Russia).

[2] E. C. Taylor remarked (*Ibis*, 1859, p. 51), that the buff-backed heron, *Ardea bubulcus*, was made by the tourists' dragomans to do duty for the "sacred ibis," and this seems to be no novel practice, since by it, or something like it, Hasselqvist was misled, and through him Linnaeus.

[3] The ibis has more than once nested in the gardens of the Zoological Society in London, and even reared its young there.

[4] For some account of these may be consulted Dr Reichenow's paper in *Journ. für Ornithologie* (1877), pp. 143-156; Elliot's in *Proc. Zool. Society* (1877), pp. 477-510; and that of Oustalet in *Nouv. Arch. du Muséum*, ser. 2, vols. i. pp. 167-184.

[5] It is a popular error—especially among painters—that this bird was the sacred ibis of the Egyptians.

ibis, *I. pagana*, have been found in considerable numbers in the middle Tertiary beds of France.[1] (A. N.)

IBLIS, or EBLIS, in Moslem mythology the counterpart of the Christian and Jewish devil. He figures oftener in the Koran under the name Shaitan, Iblis being mentioned 11 times, whereas Shaitan appears in 87 passages. He is chief of the spirits of evil, and his personality is adapted to that of his Jewish prototype. Iblis rebelled against Allah and was expelled from Paradise. The Koranic legend is that his fall was a punishment for his refusal to worship Adam. Condemned to death he was afterwards respited till the judgment day (Koran vii. 13).

See Gustav Weil, *The Bible, the Koran and the Talmud* (London, 1846).

IBN 'ABD RABBIHI [Abū 'Umar Aḥmad ibn Maḥommed ibn 'Abd Rabbihi] (860–940), Arabian poet, was born in Cordova and descended from a freed slave of Hishām, the second Spanish Omayyad caliph. He enjoyed a great reputation for learning and eloquence. No diwan of his is extant, but many selections from his poems are given in the *Yatīmat ud-Dahr*, i. 412-436 (Damascus, 1887). More widely known than his poetry is his great anthology, the *'Iqd ul-Farīd* ("The Precious Necklace"), a work divided into twenty-five sections, the thirteenth being named the middle jewel of the necklace, the chapters on either side of this being named after other jewels. It is an *adab* book (see ARABIA: *Literature*, section "Belles Lettres") resembling Ibn Qutaiba's *'Uyūn ul-Akhbār*, from which it borrows largely. It has been printed several times in Cairo (1876, 1886, &c.). (G. W. T.)

IBN 'ARABĪ [Muḥyiuddīn Abū 'Abdallāh ibn ul-'Arabī] (1165–1240), Moslem theologian and mystic, was born in Murcia and educated in Seville. When thirty-eight he travelled in Egypt, Arabia, Bagdad, Mosul and Asia Minor, after which he lived in Damascus for the rest of his life. In law he was a Zahirite, in theology a mystic of the extreme order, though professing orthodox Ash'arite theology and combating in many points the Indo-Persian mysticism (pantheism). He claims to have had conversations with all the prophets past and future, and reports conversations with God himself. Of his numerous works about 150 still exist. The most extensive is the twelve-volume *Futūḥāt ul-Makkīyāt* ("Meccan Revelations"), a general encyclopaedia of Sufic beliefs and doctrines. Numerous extracts from this work are contained in Sha'rānī's (d. 1565) manual of Sufic dogma (*Yawāqīt*) published several times in Cairo. A short account of these works is given in A. von Kremer's *Geschichte der herrschenden Ideen des Islams*, pp. 102-109 (Leipzig, 1868). Another characteristic and more accessible work of Ibn 'Arabi is the *Fuṣūṣ ul-Ḥikam*, on the nature and importance of the twenty-seven chief prophets, written in 1230 (ed. Bulāq, 1837) and with the *Commentary* (Cairo, 1891) of Qāshāni (d. 1350); cf. analysis by M. Schreiner in *Journal of German Oriental Society*, lii. 516-525.

Of some 289 works said to have been written by Ibn 'Arabī 150 are mentioned in C. Brockelmann's *Gesch. der arabischen Litteratur*, vol. i. (Weimar, 1898), pp. 441-448. See also R. A. Nicholson, *A Literary History of the Arabs*, pp. 399-404 (London, 1907). (G. W. T.)

IBN ATHĪR, the family name of three brothers, all famous in Arabian literature, born at Jazīrat ibn 'Umar in Kurdistan. The eldest brother, known as MAJD UD-DĪN (1149–1210), was long in the service of the amir of Mosul, and was an earnest student of tradition and language. His dictionary of traditions (*Kitāb un-Nihāya*) was published at Cairo (1893), and his dictionary of family names (*Kitāb ul-Murassa'*) has been edited by Seybold (Weimar, 1896). The youngest brother, known as DIYĀ UD-DĪN (1163–1239), served Saladin from 1191 on, then his son, al-Malik ul-Afdal, and was afterwards in Egypt, Samosata, Aleppo, Mosul and Bagdad. He was one of the most famous aesthetic and stylistic critics in Arabian literature. His *Kitāb ul-Mathal*, published in Bulāq in 1865 (cf. *Journal of the German Oriental Society*, xxxv. 148, and Goldziher's *Abhandlungen*, i. 161 sqq.), contains some very independent criticism of ancient and modern Arabic verse. Some of his letters have been published by D. S. Margoliouth "On the Royal Correspondence of Diya ed-Din el-Jazari" in the *Actes du dixième congrès international des orientalistes*, sect. 3, pp. 7-21.

The brother best known by the simple name of Ibn Athīr was ABU-L-ḤASAN 'IZZUDDĪN MAHOMMED IBN UL-ATHĪR (1160–1234), who devoted himself to the study of history and tradition. At the age of twenty-one he settled with his father in Mosul and continued his studies there. In the service of the amir for many years, he visited Bagdad and Jerusalem and later Aleppo and Damascus. He died in Mosul. His great history, the *Kāmil*, extends to the year 1231; it has been edited by C. J. Tornberg, *Ibn al-Athiri Chronicon quod perfectissimum inscribitur* (14 vols., Leiden, 1851–1876), and has been published in 12 vols. in Cairo (1873 and 1886). The first part of this work up to A.H. 310 (A.D. 923) is an abbreviation of the work of Ṭabarī (*q.v.*) with additions. Ibn Athīr also wrote a history of the Atabegs of Mosul, published in the *Recueil des historiens des croisades* (vol. ii., Paris); a work (*Usd ul-Ghāba*), giving an account of 7500 companions of Mahomet (5 vols., Cairo, 1863), and a compendium (the *Lubāb*) of Sam'āni's *Kitāb ul-Anṣāb* (cf. F. Wüstenfeld's *Specimen el-Lobabi*, Göttingen, 1835). (G. W. T.)

IBN BATUTA, *i.e.* ABU ABDULLAH MAHOMMED, surnamed IBN BATUTA (1304–1378), the greatest of Moslem travellers, was born at Tangier in 1304. He entered on his travels at twenty-one (1325) and closed them in 1355. He began by traversing the coast of the Mediterranean from Tangier to Alexandria, finding time to marry two wives on the road. After some stay at Cairo, then probably the greatest city in the world (excluding China), and an unsuccessful attempt to reach Mecca from Aidhab on the west coast of the Red Sea, he visited Palestine, Aleppo and Damascus. He then made the pilgrimage to Mecca and Medina, and visited the shrine of Ali at Mashhad-Ali, travelling thence to Basra, and across the mountains of Khuzistan to Isfahan, thence to Shiraz and back to Kufa and Bagdad. After an excursion to Mosul and Diarbekr, he made the *haj* a second time, staying at Mecca three years. He next sailed down the Red Sea to Aden (then a place of great trade), the singular position of which he describes, noticing its dependence for water-supply upon the great cisterns restored in modern times. He continued his voyage down the African coast, visiting, among other places, Mombasa and Quiloa (Kilwa). Returning north he passed by the chief cities of Oman to New Ormuz (Hurmuz), which had about 15 years before, *c.* 1315, been transferred to its famous island-site from the mainland (Old Ormuz). After visiting other parts of the gulf he crossed the breadth of Arabia to Mecca, making the *haj* for the third time. Crossing the Red Sea, he made a journey of great hardship to Syene, and thence along the Nile to Cairo. After this, travelling through Syria, he made a circuit among the petty Turkish states into which Asia Minor was divided after the fall of the kingdom of Rum (Iconium). He now crossed the Black Sea to Kaffa, then mainly occupied by the Genoese, and apparently the first Christian city he had seen, for he was much perturbed by the bell-ringing. He next travelled into Kipchak (the Mongol khanate of Russia), and joined the camp of the reigning khan Mahommed Uzbeg, from whom the great and heterogeneous *Uzbeg* race is perhaps named. Among other places in this empire he travelled to Bolghar (54° 54′ N.) in order to witness the shortness of the summer night, and desired to continue his travels north into the "Land of Darkness" (in the extreme north of Russia), of which wonderful things were told, but was obliged to forego this. Returning to the khan's camp he joined the cortège of one of the Khatuns, who was a Greek princess by birth (probably illegitimate) and in her train travelled to Constantinople, where he had an interview with the emperor Andronikos III. the Younger (1328–1341). He tells how, as he passed the city gates, he heard the guards muttering *Sarakinu*. Returning to the court of Uzbeg, at Sarai on the Volga, he crossed the steppes to Khwarizm and Bokhara; thence through Khorasan and Kabul, and over the Hindu Kush (to which he gives that name, its first occurrence). He reached

[1] The name "*Ibis*" was selected as the title of an ornithological magazine, frequently referred to in this and other articles, which made its first appearance in 1859.

the Indus, on his own statement, in September, 1333. This closes the first part of his narrative.

From Sind, which he traversed to the sea and back again, he proceeded to Multan, and eventually, on the invitation of Mahommed Tughlak, the reigning sovereign, to Delhi. Mahommed was a singular character, full of pretence at least to many accomplishments and virtues, the founder of public charities, and a profuse patron of scholars, but a parricide, a fratricide, and as madly capricious, bloodthirsty and unjust as Caligula. "No day did his palace gate fail to witness the elevation of some abject to affluence and the torture and murder of some living soul." He appointed the traveller to be kazi of Delhi, with a present of 12,000 silver dinars (rupees), and an annual salary of the same amount, besides an assignment of village lands. In the sultan's service Ibn Batuta remained eight years; but his good fortune stimulated his natural extravagance, and his debts soon amounted to four or five times his salary. At last he fell into disfavour and retired from court, only to be summoned again on a congenial duty. The emperor of China, last of the Mongol dynasty, had sent a mission to Delhi, and the Moor was to accompany the return embassy (1342). The party travelled through central India to Cambay and thence sailed to Calicut, classed by the traveller with the neighbouring Kaulam (Quilon), Alexandria, Sudak in the Crimea, and Zayton (Amoy harbour) in China, as one of the greatest trading havens in the world—an interesting enumeration from one who had seen them all. The mission party was to embark in Chinese junks (the word used) and smaller vessels, but that carrying the other envoys and the presents, which started before Ibn Batuta was ready, was wrecked totally; the vessel that he had engaged went off with his property, and he was left on the beach of Calicut. Not daring to return to Delhi, he remained about Honore and other cities of the western coast, taking part in various adventures, among others the capture of Sindabur (Goa), and visiting the Maldive Islands, where he became kazi, and married four wives, and of which he has left the best medieval account, hardly surpassed by any modern. In August 1344 he left the Maldives for Ceylon; here he made the pilgrimage to the "Footmark of our Father Adam." Thence he betook himself to Maabar (the Coromandel coast), where he joined a Mussulman adventurer, residing at Madura, who had made himself master of much of that region. After once more visiting Malabar, Canara and the Maldives, he departed for Bengal, a voyage of forty-three days, landing at Sadkawan (Chittagong). In Bengal he visited the famous Moslem saint Shaykh Jalaluddin, whose shrine (*Shah Jalal* at Silhet) is still maintained. Returning to the delta, he took ship at Sunarganw (near Dacca) on a junk bound for Java (*i.e. Java Minor* of Marco Polo, or Sumatra). Touching the coast of Arakan or Burma, he reached Sumatra in forty days, and was provided with a junk for China by Malik al Dhahir, a zealous disciple of Islam, which had recently spread among the states on the northern coast of that island. Calling (apparently) at Cambodia on his way, Ibn Batuta reached China at Zayton (Amoy harbour), famous from Marco Polo; he also visited Sin Kalan or Canton, and professes to have been in Khansa (*Kinsay* of Marco Polo, *i.e.* Hangchau), and Khanbalik (*Cambaluc* or Peking). The truth of his visit to these two cities, and especially to the last, has been questioned. The traveller's history, not least in China, singularly illustrates the free masonry of Islam, and its power of carrying a Moslem doctor over the known world of Asia and Africa. On his way home he saw the great bird *Rukh* (evidently, from his description, an island lifted by refraction); revisited Sumatra, Malabar, Oman, Persia, Bagdad, and crossed the great desert to Palmyra and Damascus, where he got his first news of home, and heard of his father's death fifteen years before. Diverging to Hamath and Aleppo, on his return to Damascus, he found the Black Death raging, so that two thousand four hundred died in one day. Revisiting Jerusalem and Cairo he made the *haj* a fourth time, and finally reappeared at Fez (visiting Sardinia *en route*) on the 8th of November 1349, after twenty-four years' absence. Morocco, he felt, was, after all, the best of countries. "The *dirhems* of the West are but little; but then you get more for them." After going home to Tangier, Ibn Batuta crossed into Spain and made the round of Andalusia, including Gibraltar, which had just then stood a siege from the "Roman tyrant Adfunus" (Alphonso XI. of Castile, 1312–1350). In 1352 the restless man started for Central Africa, passing by the oases of the Sahara (where the houses were built of rock-salt, as Herodotus tells, and roofed with camel skins) to Timbuktu and Gogo on the Niger, a river which he calls the Nile, believing it to flow down into Egypt, an opinion maintained by some up to the date of Lander's discovery. Being then recalled by his own king, he returned to Fez (early in 1354) via Takadda, Haggar and Tuat. Thus ended his twenty-eight years' wanderings which in their main lines alone exceeded 75,000 m. By royal order he dictated his narrative to Mahommed Ibn Juzai, who concludes the work, 13th of December 1355 (A.D.) with the declaration: "This Shaykh is the traveller of our age; and he who should call him the traveller of the whole body of Islam would not exceed the truth." Ibn Batuta died in 1378, aged seventy-three.

Ibn Batuta's travels have only been known in Europe during the 19th century; at first merely by Arabic abridgments in the Gotha and Cambridge libraries. Notices or extracts had been published by Seetzen (*c.* 1808), Kosegarten (1818), Apetz (1819), and Burckhardt (1819), when in 1829 Dr S. Lee published for the Oriental Translation Fund a version from the abridged MSS. at Cambridge, which attracted much interest. The French capture of Constantina afforded MSS. of the complete work, one of them the autograph of Ibn Juzai. And from these, after versions of fragments by various French scholars, was derived at last (1858–1859) the standard edition and translation of the whole by M. Défrémery and Dr Sanguinetti, in 4 vols. See also Sir Henry Yule, *Cathay*, ii. 397-526; C. Raymond Beazley, *Dawn of Modern Geography*, iii. 535-538. Though there are some singular chronological difficulties in the narrative, and a good many cursory inaccuracies and exaggerations, there is no part of it except, perhaps, certain portions of the journeys in north China, which is open to doubt. The accounts of the Maldive Islands, and of the Negro countries on the Niger, are replete with interesting and accurate particulars. The former agrees surprisingly with that given by the only other foreign resident we know of, Pyrard de la Val, two hundred and fifty years later. Ibn Batuta's statements and anecdotes regarding the showy virtues and solid vices of Sultan Muhammad Tughlak are in entire agreement with Indian historians, and add many fresh details. (H. Y.; C. R. B.)

IBN DURAID [Abū Bakr Mahommed ibn ul-Ḥasan ibn Duraid ul-Azdī] (837–934), Arabian poet and philologist, was born at Baṣra of south Arabian stock. At his native place he was trained under various teachers, but fled in 871 to Oman at the time Baṣra was attacked by the negroes, known as the Zanj, under Muhallabī. After living twelve years in Oman he went to Persia, and, under the protection of the governor, 'Abdallāh ibn Mahommed ibn Mīkāl, and his son, Isma'īl, wrote his chief works. In 920 he went to Bagdad, where he received a pension from the caliph Moqtadir.

The *Maqsūra*, a poem in praise of Ibn Mīkāl and his son, has been edited by A. Haitsma (1773) E. Scheidius (1786) and N. Boyesen (1828). Various commentaries on the poem exist in MS. (cf. C. Brockelmann, *Gesch. der ar. Lit.*, i. 211 ff., Weimar, 1898). The *Jamhara fi-l-Lugha* is a large dictionary written in Persian but not printed. Another work is the *Kitāb ul-Ishtiqāq* ("Book of Etymology"), edited by F. Wüstenfeld (Göttingen, 1854); it was written in opposition to the anti-Arabian party to show the etymological connexion of the Arabian tribal names. (G. W. T.)

IBN FARADĪ [Abū-l-Walīd 'Abdallāh ibn ul-Faradi] (962–1012), Arabian historian, was born at Cordova and studied law and tradition. In 992 he made the pilgrimage and proceeded to Egypt and Kairawān, studying in these places. After his return in 1009 he became cadi in Valencia, and was killed at Cordova when the Berbers took the city.

His chief work is the *History of the Learned Men of Andalusia*, edited by F. Codera (Madrid, 1891–1892). He wrote also a history of the poets of Andalusia. (G. W. T.)

IBN FĀRID [Abū-l-Qāsim 'Umar ibn ul-Fāriḍ] (1181–1235), Arabian poet, was born in Cairo, lived for some time in Mecca and died in Cairo. His poetry is entirely Sufic, and he was esteemed the greatest mystic poet of the Arabs. Some of his poems are said to have been written in ecstasies. His diwan has been published with commentary at Beirūt, 1887, &c.; with the commentaries of Burīnī (d. 1615) and 'Abdul-Ghānī (d. 1730) at Marseilles, 1853, and at Cairo; and with the commentary of Rushayyid Ghālib

(19th century) at Cairo, 1893. One of the separate poems was edited by J. von Hammer Purgstall as *Das arabische hohe Lied der Liebe* (Vienna, 1854).

See R. A. Nicholson, *A Literary History of the Arabs* (London, 1907), pp. 394-398. (G. W. T.)

IBN GABIROL [Solomon ben Judah], Jewish poet and philosopher, was born at Malaga, probably about 1021. The early part of his troublous life was spent at Saragossa, but few personal details of it are recorded. His parents died while he was a child and he was under the protection first of a certain Jekuthiel, who died in 1039, and afterwards of Samuel ha-Nagid, the well-known patron of learning. His passionate disposition, however, embittered no doubt by his misfortunes, involved him in frequent difficulties and led to his quarrelling with Samuel. It is generally agreed that he died young, although the date is uncertain. Al Harizi[1] says at the age of twenty-nine, and Moses b. Ezra[2] about thirty, but Abraham Zaccuto[3] states that he died (at Valencia) in 1070. M. Steinschneider[4] accepts the date 1058.

His literary activity began early. He is said to have composed poems at the age of sixteen, and elegies by him are extant on Hai Gaon (died in 1038) and Jekuthiel (died in 1039), each of which was written probably soon after the death of the person commemorated. About the same time he also wrote his *'Anaq*, a poem on grammar, of which only 97 lines out of 400 are preserved. Moses ben Ezra says of him that he imitated Moslem models, and was the first to open to Jewish poets the door of versification,[5] meaning that he first popularized the use of Arabic metres in Hebrew. It is as a poet that he has been known to the Jews to the present day, and admired for the youthful freshness and beauty of his work, in which he may be compared to the romantic school in France and England in the early 19th century. Besides his lyrical and satirical poems, he contributed many of the finest compositions to the liturgy (some of them with the acrostic "Shelomoh ha-qaṭōn"), which are widely different from the artificial manner of the earlier payyeṭanim. The best known of his longer liturgical compositions are the philosophical *Kether Malkūth* (for the Day of Atonement) and the *Azharōth*, on the 613 precepts (for *Shebhu'ōth*). Owing to his pure biblical style he had an abiding influence on subsequent liturgical writers.

Outside the Jewish community he was known as the philosopher Avicebron (Avencebrol, Avicebrol, &c.) The credit of identifying this name as a medieval corruption of Ibn Gabirol is due to S. Munk, who showed that selections made by Shem Tōbh Palqera (or Falqera) from the Meqōr Ḥayyīm (the Hebrew translation of an Arabic original) by Ibn Gabirol, corresponded to the Latin *Fons Vitae* of Avicebron. The Latin version, made by Johannes Hispalensis and Gundisalvi about one hundred years after the author's death, had at once become known among the Schoolmen of the 12th century and exerted a powerful influence upon them, although so little was known of the author that it was doubted whether he was a Christian or a Moslem. The teaching of the *Fons Vitae* was entirely new to the country of its origin, and being drawn largely from Neoplatonic sources could not be expected to find favour with Jewish thinkers. Its distinctive doctrines are: (1) that all created beings, spiritual or corporeal, are composed of matter and form, the various species of matter being but varieties of the universal matter, and similarly all forms being contained in one universal form; (2) that between the primal One and the intellect (the *νοῦς* of Plotinus) there is interposed the divine Will, which is itself divine and above the distinction of form and matter, but is the cause of their union in the being next to itself, the intellect, in which Avicebron holds that the distinction does exist. The doctrine that there is a material, as well as a formal, element in all created beings was explicitly adopted from Avicebron by Duns Scotus (as against the view of Albertus Magnus and Thomas Aquinas), and perhaps his exaltation of the will above the intellect is due to the same influence. Avicebron develops his philosophical system throughout quite independently of his religious views—a practice wholly foreign to Jewish teachers, and one which could not be acceptable to them. Indeed, this charge is expressly brought against him by Abraham ben David of Toledo (died in 1180). It is doubtless this non-religious attitude which accounts for the small attention paid to the *Fons Vitae* by the Jews, as compared with the wide influence of the philosophy of Maimonides.

The other important work of Ibn Gabirol is *Iṣlāḥ al-akhlāq* (the improvement of character), a popular work in Arabic, translated into Hebrew (*Tiqqūn middōth ha-nephesh*) by Judah ibn Tibbon. It is widely different in treatment from the *Fons*, being intended as a practical not a speculative work.

The collection of moral maxims, compiled in Arabic but best known (in the Hebrew translation of Judah ibn Tibbon) as *Mibḥar ha-penīnīm*, is generally ascribed to Ibn Gabirol, though on less certain grounds.

Bibliography.—Texts of the liturgical poems are to be found in the prayer-books: others in Dukes and Edelmann, *Treasures of Oxford* (Oxford, 1850); Dukes, *Shīrē Shelomoh* (Hanover, 1858); S. Sachs, *Shīr ha-shīrīm asher li-Shelomoh* (Paris, 1868, incomplete); Brody, *Die weltlichen Gedichte des . . . Gabirol* (Berlin, 1897, &c.).

"Avencebrolis Fons Vitae" (Latin text) in Clemens Bäumker's *Beiträge zur Gesch. d. Philosophie*, Bd. i. Hefte 2-4 (Münster, 1892); *The Improvement of the Moral Qualities* [Arabic and English] ed. by S. S. Wise (New York, 1901); *A Choice of Pearls* [Hebrew and English] ed. by Ascher (London, 1859).

On the philosophy in general: S. Munk, *Mélanges* (quoted above); Guttmann, *Die Philosophie des Sal.-ibn Gabirol* (Göttingen, 1889); D. Kaufmann, *Studien über Sal.-ibn Gabirol* (Budapest, 1899); S. Horovitz, "Die Psychologie Ibn Gabirols," in the *Jahresbericht des jüd. theol. Seminars Fränckel'scher Stiftung* (Breslau, 1900); Wittmann, "Zur Stellung Avencebrols . . ." (in Bäumker's *Beiträge*, Bd. v. Heft 1, Münster, 1905). (A. Cy.)

IBN HAUḲAL, strictly Ibn Hauqal, a 10th century Arabian geographer. Nothing is known of his life. His work on geography, written in 977, is only a revision and extension of the *Masālik ul-Mamālik* of al-Iṣṭakhrī, who wrote in 951. This itself was a revised edition of the *Kitāb ul-Ashkāl* or *Ṣuwar ul-Aqālim* of Abū Zaid ul-Balkhī, who wrote about 921. Ibn Hauḳal's work was published by M. J. de Goeje (Leiden, 1873). An anonymous epitome of the book was written in 1233.

See M. J. de Goeje, "Die Iṣṭahrī-Balhī Frage," in the *Zeitschrift der deutschen Morgenländischen Gesellschaft*, xxv. 42 sqq.

IBN ḤAZM [Abū Mahommed 'Alī ibn Aḥmad ibn Ḥazm] (994–1064), Moslem theologian, was born in a suburb of Cordova. He studied history, law and theology, and became a vizier as his father had been before him, but was deposed for heresy, and spent the rest of his life quietly in the country. In legal matters he belonged first to the Shāfi'ite school, but came to adopt the views of the Zāhirites, who admitted only the external sense of the Koran and tradition, disallowing the use of analogy (*Qiyās*) and *Taqlīd* (appeal to the authority of an imām), and objecting altogether to the use of individual opinion (*Ra'y*). Every sentence of the Koran was to be interpreted in a general and universal sense; the special application to the circumstances of the time it was written was denied. Every word of the Koran was to be taken in a literal sense, but that sense was to be learned from other uses in the Koran itself, not from the meaning in other literature of the time. The special feature of Ibn Ḥazm's teaching was that he extended the application of these principles from the study of law to that of dogmatic theology. He thus found himself in opposition at one time to the Mo'tazilites, at another to the Ash'arites. He did not, however, succeed in forming a school. His chief work is the *Kitāb ul-Milal wan-Niḥal*, or "Book of Sects" (published in Cairo, 1899).

For his teaching cf. I. Goldziher, *Die Zahiriten*, pp. 116-172 (Leipzig, (1884), and M. Schreiner in the *Journal of the German Oriental Society*, lii. 464-486. For a list of his other works see C. Brockelmann's *Geschichte der arabischen Literatur*, vol. i. (Weimar, 1898), p. 400. (G. W. T.)

IBN HISHĀM [Abū Maḥommed ʽAbdulmalik ibn Hishām ibn Ayyūb ul-Himyarī] (d. 834), Arabian biographer, studied in Kufa but lived afterwards in Fostāt (old Cairo), where he gained a name as a grammarian and student of language and history. His chief work is his edition of Ibn Isḥāq's (*q.v.*) *Life of the Apostle of God*, which has been edited by F. Wüstenfeld (Göttingen, 1858–1860). An abridged German translation has been made by G. Weil (Stuttgart, 1864; cf. P. Brönnle, *Die Commentatoren des Ibn Isḥaq und ihre Scholien*, Halle, 1895). Ibn Hishām is said to have written a work explaining the difficult words which occur in poems on the life of the Apostle, and another on the genealogies of the Himyarites and their princes. (G. W. T.)

IBN ISHĀQ [Maḥommed ibn Isḥāq Abū ʽAbdallāh] (d. 768), Arabic historian, lived in Medina, where he interested himself to such an extent in the details of the Prophet's life that he was attacked by those to whom his work seemed to have a rationalistic tendency. He consequently left Medina in 733, and went to Alexandria, then to Kufa and Hira, and finally to Bagdad, where the caliph Manṣūr provided him with the means of writing his great work. This was the *Life of the Apostle of God*, which is now lost and is known to us only in the recension of Ibn Hishām (*q.v.*). The work has been attacked by Arabian writers (as in the *Fihrist*) as untrustworthy, and it seems clear that he introduced forged verses (cf. *Journal of the German Oriental Society*, xiv. 288 sqq.). It remains, however, one of the most important works of the age. (G. W. T.)

IBN JUBAIR [Abū-l Ḥusain Maḥommed ibn Aḥmad ibn Jubair] (1145–1217), Arabian geographer, was born in Valencia. At Granada he studied the Koran, tradition, law and literature, and later became secretary to the Mohad governor of that city. During this time he composed many poems. In 1183 he left the court and travelled to Alexandria, Jerusalem, Medina, Mecca, Damascus, Mosul and Bagdad, returning in 1185 by way of Sicily.

The *Travels of Ibn Jubair* were edited by W. Wright (Leiden, 1852); and a new edition of this text, revised by M. J. de Goeje, was published by the Gibb Trustees (London, 1907). The part relating to Sicily was published, with French translation and notes, by M. Amari in the *Journal asiatique* (1845–1846) and a French translation alone of the same part by G. Crolla in *Museon*, vi. 123-132. (G. W. T.)

IBN KHALDŪN [Abū Zaid ibn Maḥommed ibn Maḥommed ibn Khaldūn] (1332–1406), Arabic historian, was born at Tunis. He studied the various branches of Arabic learning with great success. In 1352 he obtained employment under the Marīnid sultan Abū Inān (Faris I.) at Fez. In the beginning of 1356, his integrity having been suspected, he was thrown into prison until the death of Abū Inān in 1358, when the vizier al-Hasan ibn Omar set him at liberty and reinstated him in his rank and offices. He here continued to render great service to Abu Salem (Ibrahim III.), Abū Inān's successor, but, having offended the prime minister, he obtained permission to emigrate to Spain, where, at Granada, he was received with great cordiality by Ibn al Ahmar, who had been greatly indebted to his good offices when an exile at the court of Abu Salem. The favours he received from the sovereign excited the jealousy of the vizier, and he was driven back to Africa (1364), where he was received with great cordiality by the sultan of Bougie, Abu Abdallah, who had been formerly his companion in prison. On the fall of Abu Abdallah Ibn Khaldūn raised a large force amongst the desert Arabs, and entered the service of the sultan of Tlemçen. A few years later he was taken prisoner by Abdalaziz (ʽAbd ul ʽAzīz), who had defeated the sultan of Tlemçen and seized the throne. He then entered a monastic establishment, and occupied himself with scholastic duties, until in 1370 he was sent for to Tlemçen by the new sultan. After the death of ʽAbd ul ʽAzīz he resided at Fez, enjoying the patronage and confidence of the regent. After some further vicissitudes in 1378 he entered the service of the sultan of his native town of Tunis, where he devoted himself almost exclusively to his studies and wrote his history of the Berbers. Having received permission to make the pilgrimage to Mecca, he reached Cairo, where he was presented to the sultan, al-Malik udh-Dhahir Barkuk, who insisted on his remaining there, and in the year 1384 made him grand cadi of the Malikite rite for Cairo. This office he filled with great prudence and probity, removing many abuses in the administration of justice in Egypt. At this time the ship in which his wife and family, with all his property, were coming to join him, was wrecked, and every one on board lost. He endeavoured to find consolation in the completion of his history of the Arabs of Spain. At the same time he was removed from his office of cadi, which gave him more leisure for his work. Three years later he made the pilgrimage to Mecca, and on his return lived in retirement in the Fayum until 1399, when he was again called upon to resume his functions as cadi. He was removed and reinstated in the office no fewer than five times.

In 1400 he was sent to Damascus, in connexion with the expedition intended to oppose Timur or Tamerlane. When Timur had become master of the situation, Ibn Khaldūn let himself down from the walls of the city by a rope, and presented himself before the conqueror, who permitted him to return to Egypt. Ibn Khaldūn died on the 16th of March 1406, at the age of sixty-four.

The great work by which he is known is a "Universal History," but it deals more particularly with the history of the Arabs of Spain and Africa. Its Arabic title is *Kitāb ul'Ibar, wa dīwān el Mubtada wa'l Khabar, fī ayyām ul'Arab wa'l'Ajām wa'l Berber*; that is, "The Book of Examples and the Collection of Origins and Information respecting the History of the Arabs, Foreigners and Berbers." It consists of three books, an introduction and an autobiography. Book i. treats of the influence of civilization upon man; book ii. of the history of the Arabs and other peoples from the remotest antiquity until the author's own times; book iii. of the history of the Berber tribes and of the kingdoms founded by that race in North Africa. The introduction is an elaborate treatise on the science of history and the development of society, and the autobiography contains the history, not only of the author himself, but of his family and of the dynasties which ruled in Fez, Tunis and Tlemçen during his lifetime. An edition of the Arabic text has been printed at Būlāq, (7 vols., 1867) and a part of the work has been translated by the late Baron McG. de Slane under the title of *Histoire des Berbères* (Algiers, 1852–1856); it contains an admirable account of the author and analysis of his work. Vol. i., the *Muqaddama* (preface), was published by M. Quatremère (3 vols., Paris, 1858), often republished in the East, and a French translation was made by McG. de Slane (3 vols., Paris, 1862–1868). The parts of the history referring to the expeditions of the Franks into Moslem lands were edited by C. J. Tornberg (Upsala, 1840), and the parts treating of the Banu-l Aḥmar kings of Granada were translated into French by M. Gaudefroy-Demombynes in the *Journal asiatique*, ser. 9, vol. xiii. The *Autobiography* of Ibn Khaldūn was translated into French by de Slane in the *Journal asiatique*, ser. 4, vol. iii. For an English appreciation of the philosophical spirit of Ibn Khaldūn see R. Flint's *History of the Philosophy of History* (Edinburgh, 1893), pp. 157-170. (E. H. P.; G. W. T.)

IBN KHALLIKĀN [Abū-l ʽAbbās Aḥmad ibn Khallikān] (1211–1282), Arabian biographer, was born at Arbela, the son of a professor reputed to be ascended from the Barmecides of the court of Harun al-Rashid. When eighteen he went to Aleppo, where he studied for six years, then to Damascus, and in 1238 to Alexandria and Cairo. In 1252 he married and became chief cadi of Syria in Damascus in 1261. Having held this office for ten years, he was professor in Cairo until 1278, when he again took office in Damascus for three years. In 1281 he accepted a professorship in the same city, but died in the following year.

His great work is the *Kitab Wafayāt ul-A'yān*, "The Obituaries of Eminent Men." It contains in alphabetical order the lives of the most celebrated persons of Moslem history and literature, except those of Mahomet, the four caliphs and the companions of Mahomet and their followers (the *Tābiūn*). The work is anecdotal and contains many brief extracts from the poetry of the writers. It was published by F. Wüstenfeld (Göttingen, 1835–1843), in part by McG. de Slane (Paris, 1838–1842), and also in Cairo (1859 and 1882). An English translation by McG. de Slane was published for the Oriental Translation Fund in 4 vols. (London, 1842–1871). Thirteen extra biographies from a manuscript in Amsterdam were published by Pijnappel (Amsterdam, 1845). A Persian translation exists in manuscript, and various extracts from the work are known. Several supplements to the book have been written, the best known being that of Maḥommed ibn Shākir (d. 1362), published at Cairo 1882. A collection of poems by Ibn Khallikān is also extant. (G. W. T.)

IBN QUTAIBA, or KOTAIBA [Abū Maḥommed ibn Muslim ibn Qutaiba] (828–889), Arabian writer, was born at Bagdad or

Kufa, and was of Iranian descent, his father belonging to Merv. Having studied tradition and philology he became cadi in Dinawār and afterwards teacher in Bagdad, where he died. He was the first representative of the eclectic school of Bagdad philologists that succeeded the schools of Kufa and Baṣra (see ARABIA: *Literature*, section "Grammar"). Although engaged also in theological polemic (cf. I. Goldziher, *Muhammedanische Studien*, ii. 136, Halle, 1890), his chief works were directed to the training of the ideal secretary. Of these five may be said to form a series. The *Adab ul-Kātib* ("Training of the Secretary") contains instruction in writing and is a compendium of Arabic style. It has been edited by Max Grünert (Leiden, 1900). The *Kitāb ush-Sharāb* is still in manuscript. The *Kitāb ul-Ma'ārif* has been edited by F. Wüstenfeld as the *Handbuch der Geschichte* [1] (Göttingen, 1850); the *Kitāb ush-Shi'r wash-Shu'arāi* ("Book of Poetry and Poets") edited by M. J. de Goeje (Leiden, 1904).[2] The fifth and most important is the '*Uyūn ul-Akhbār*, which deals in ten books with lordship, war, nobility, character, science and eloquence, asceticism, friendship, requests, foods and women, with many illustrations from history, poetry and proverb (ed. C. Brockelmann, Leiden, 1900 sqq.).

For other works (which were much quoted by later Arabian writers) see C. Brockelmann, *Gesch. der arabischen Literatur*, vol. i. (Weimar, 1898), pp. 120-122. (G. W. T.)

IBN ṢA'D [Abū 'Abdallāh Maḥommed ibn Ṣa'd ibn Mani' uz-Zuhrī, often called Kātib ul-Waqidī ("secretary of Waqidī") of Baṣra] (d. 845), Arabian biographer, received his training in tradition from Waqidī and other celebrated teachers. He lived for the most part in Bagdad, and had the reputation of being both trustworthy and accurate in his writings, which, in consequence, were much used by later writers. His work, the *Kitāb ul-Ṭabaqāt ul-Kabīr* (15 vols.) contains the lives of Mahomet, his Companions and Helpers (including those who fought at Badr as a special class) and of the following generation (the Followers) who received their traditions from the personal friends of the Prophet.

This work has been edited under the superintendence of E. Sachau (Leiden, 1904 sqq.); cf. O. Loth, *Das Classenbuch des Ibn Sa'd* (Leipzig, 1869). (G. W. T.)

IBN TIBBON, a family of Jewish translators, who flourished in Provence in the 12th and 13th centuries. They all made original contributions to philosophical and scientific literature, but their permanent fame is based on their translations. Between them they rendered into Hebrew all the chief Jewish writings of the middle ages. These Hebrew translations were, in their turn, rendered into Latin (by Buxtorf and others) and in this form the works of Jewish authors found their way into the learned circles of Europe. The chief members of the Ibn Tibbon family were (1) JUDAH BEN SAUL (1120–1190), who was born in Spain but settled in Lunel. He translated the works of Baḥya, Halevi, Saadiah and the grammatical treatises of Janaḥ. (2) His son, SAMUEL (1150–1230), translated the *Guide of the Perplexed* by Maimonides. He justly termed his father "the father of the Translators," but Samuel's own method surpassed his father's in lucidity and fidelity to the original. (3) Son of Samuel, MOSES (died 1283). He translated into Hebrew a large number of Arabic books (including the Arabic form of Euclid). The Ibn Tibbon family thus rendered conspicuous services to European culture, and did much to further among Jews who did not understand Arabic the study of science and philosophy. (I. A.)

IBN ṬUFAIL, or ṬOFAIL [Abū Bakr Maḥommed ibn 'Abd-ul-Malik ibn Ṭufail ul-Qaisī] (d. 1185), Moslem philosopher, was born at Guadix near Granada. There he received a good training in philosophy and medicine, and is said to have been a pupil of Avempace (*q.v.*). He became secretary to the governor of Granada, and later physician and vizier to the Mohad caliph, Abu Ya'qūb Yūsuf. He died at Morocco.

[1] Summary in E. G. Browne, *A Literary History of Persia* (London, 1902), pp. 387 f.

[2] The preface was translated into German by Theodor Nöldeke in his *Beiträge* (Hanover, 1864), pp. 1-51.

His chief work is a philosophical romance, in which he describes the awakening and growth of intellect in a child removed from the influences of ordinary life. Its Arabic title is *Risālat Hayy ibn Yaqzān*; it was edited by E. Pococke as *Philosophus autodidactus* (Oxford, 1671; 2nd ed., 1700), and with a French translation by L. Gauthier (Algiers, 1900). An English translation by S. Ockley was published in 1708 and has been reprinted since. A Spanish translation by F. Pons Boigues was published at Saragossa (1900). Another work of Ibn Ṭufail, the *Kitāb Asrār ul- Ḥikma ul-mashraqīyya* ("Secrets of Eastern Science"), was published at Bulāq (1882); cf. S. Munk, *Mélanges* (1859), pp. 410 sqq., and T. J. de Boer, *Geschichte der Philosophie im Islam* (Stuttgart, 1901), pp. 160 sqq. (also an English translation). (G. W. T.)

IBN USAIBI'A [Muwaffaquddīn Abū-l-'Abbās Aḥmad ibn ul-Qāsim ibn Abī Usaibi'a] (1203–1270), Arabian physician, was born at Damascus, the son of an oculist, and studied medicine at Damascus and Cairo. In 1236 he was appointed by Saladin physician to a new hospital in Cairo, but surrendered the appointment the following year to take up a post given him by the amir of Damascus in Salkhad near that city. There he lived and died. He wrote '*Uyūn ul-Anba'fī Ṭabaqāt ul-Aṭibba'* or "Lives of the Physicians," which in its first edition (1245–1246) was dedicated to the vizier of Damascus. This he enlarged, though it is uncertain whether the new edition was made public in the lifetime of the author.

Edition by A. Müller (Königsberg, 1884). (G. W. T.)

IBO, a district of British West Africa, on the lower Niger immediately above the delta, and mainly on the eastern bank of the river. The chief town, frequently called by the same name (more correctly Abo or Áboh), lies on a creek which falls into the main stream about 150 m. from its mouth and contains from 6000 to 8000 inhabitants. The Ibo are a strong well-built Negro race. Their women are distinguished by their embonpoint. The language of the Ibo is one of the most widely spoken on the lower Niger. The Rev. J. F. Schön began its reduction in 1841, and in 1861 he published a grammar (*Oku Ibo Grammatical Elements*, London, Church Miss. Soc.). (See NIGERIA.)

IBRAHĪM AL-MAUṢILĪ (742–804), Arabian singer, was born of Persian parents settled in Kufa. In his early years his parents died and he was trained by an uncle. Singing, not study, attracted him, and at the age of twenty-three he fled to Mosul, where he joined a band of wild youths. After a year he went to Rai (Rei, Rhagae), where he met an ambassador of the caliph Manṣūr, who enabled him to come to Baṣra and take singing lessons. His fame as a singer spread, and the caliph Mahdī brought him to the court. There he remained a favourite under Hādī, while Harūn al-Rashīd kept him always with him until his death, when he ordered his son (Ma'mūn) to say the prayer over his corpse. Ibrahīm, as might be expected, was no strict Moslem. Two or three times he was knouted and imprisoned for excess in wine-drinking, but was always taken into favour again. His powers of song were far beyond anything else known at the time. Two of his pupils, his son Isḥāq and Muḥāriq, attained celebrity after him.

See the Preface to W. Ahlwardt's *Abu Nowas* (Greifswald, 1861), pp. 13-18, and the many stories of his life in the *Kitāb ul-Aghānī*, v. 2-49. (G. W. T.)

IBRAHIM PASHA (1789–1848), Egyptian general, is sometimes spoken of as the adopted son of Mehemet Ali, pasha of Egypt. He is also and more commonly called his son. He was born in his father's native town, Kavala in Thrace. During his father's struggle to establish himself in Egypt, Ibrahim, then sixteen years of age, was sent as a hostage to the Ottoman capitan pasha (admiral), but when Mehemet Ali was recognized as pasha, and had defeated the English expedition under General A. M. Fraser, he was allowed to return to Egypt. When Mehemet Ali went to Arabia to prosecute the war against the Wahhabis in 1813, Ibrahim was left in command in Upper Egypt. He continued the war with the broken power of the Mamelukes, whom he suppressed. In 1816 he succeeded his brother Tusun in command of the Egyptian forces in Arabia. Mehemet Ali had already begun to introduce European discipline into his army, and Ibrahim had probably received some training, but his first campaign was conducted more in the old Asiatic style than his later operations. The campaign lasted two years, and terminated in the destruction of the Wahhabis as a political power. Ibrahim landed at Yembo, the port of Medina, on the 30th of September 1816. The holy cities had been recovered from the Wahhabis, and Ibrahim's task was to follow them into the desert of Nejd and destroy their fortresses. Such training as the Egyptian troops had received, and their artillery, gave them a marked superiority in the open field. But the difficulty of crossing the desert to the Wahhabi stronghold of Deraiya, some 400 m. east of Medina, and the courage of their opponents, made the conquest a very arduous one. Ibrahim displayed great energy and tenacity, sharing all the hardships of his army, and never allowing himself to be discouraged by failure. By the end of September 1818 he had forced the Wahhabi leader to surrender, and had taken Deraiya, which he ruined. On the 11th of December 1819 he made a triumphal entry into Cairo. After his return he gave effective support to the Frenchman, Colonel Sève (Suleiman Pasha), who was employed to drill the army on the European model. Ibrahim set an example by submitting to be drilled as a recruit. When in 1824 Mehemet Ali was appointed governor of the Morea by the sultan, who desired his help against the insurgent Greeks, he sent Ibrahim with a squadron and an army of 17,000 men. The expedition sailed on the 10th of July 1824, but was for some months unable to do more than come and go between Rhodes and Crete. The fear of the Greek fire ships stopped his way to the Morea. When the Greek sailors mutinied from want of pay, he was able to land at Modon on the 26th of February 1825. He remained in the Morea till the capitulation of the 1st of October 1828 was forced on him by the intervention of the Western powers. Ibrahim's operations in the Morea were energetic and ferocious. He easily defeated the Greeks in the open field, and though the siege of Missolonghi proved costly to his own troops and to the Turks who operated with him, he brought it to a successful termination on the 24th of April 1826. The Greek guerrilla bands harassed his army, and in revenge he desolated the country and sent thousands of the inhabitants into slavery in Egypt. These measures of repression aroused great indignation in Europe, and led first to the intervention of the English, French and Russian squadrons (see NAVARINO, BATTLE OF), and then to the landing of a French expeditionary force. By the terms of the capitulation of the 1st of October 1828, Ibrahim evacuated the country. It is fairly certain that the Turkish government, jealous of his power, had laid a plot to prevent him and his troops from returning to Egypt. English officers who saw him at Navarino describe him as short, grossly fat and deeply marked with smallpox. His obesity did not cause any abatement of activity when next he took the field. In 1831, his father's quarrel with the Porte having become flagrant, Ibrahim was sent to conquer Syria. He carried out his task with truly remarkable energy. He took Acre after a severe siege on the 27th of May 1832, occupied Damascus, defeated a Turkish army at Homs on the 8th of July, defeated another Turkish army at Beilan on the 29th of July, invaded Asia Minor, and finally routed the grand vizier at Konia on the 21st of December. The convention of Kutaiah on the 6th of May left Syria for a time in the hands of Mehemet Ali. Ibrahim was undoubtedly helped by Colonel Sève and the European officers in his army, but his intelligent docility to their advice, as well as his personal hardihood and energy, compare most favourably with the sloth, ignorance and arrogant conceit of the Turkish generals opposed to him. He is entitled to full credit for the diplomatic judgment and tact he showed in securing the support of the inhabitants, whom he protected and whose rivalries he utilized. After the campaign of 1832 and 1833 Ibrahim remained as governor in Syria. He might perhaps have administered successfully, but the exactions he was compelled to enforce by his father soon ruined the popularity of his government and provoked revolts. In 1838 the Porte felt strong enough to renew the struggle, and war broke out once more. Ibrahim won his last victory for his father at Nezib on the 24th of June 1839. But Great Britain and Austria intervened to preserve the integrity of Turkey. Their squadrons cut his communications by sea with Egypt, a general revolt isolated him in Syria, and he was finally compelled to evacuate the country in February 1841. Ibrahim spent the rest of his life in peace, but his health was ruined. In 1846 he paid a visit to western Europe, where he was received with some respect and a great deal of curiosity. When his father became imbecile in 1848 he held the regency till his own death on the 10th of November 1848.

See Edouard Gouin, *L'Égypte au XIX^e siècle* (Paris, 1847); Aimé Vingtrinier, *Soliman-Pasha* (*Colonel Sève*) (Paris, 1886). A great deal of unpublished material of the highest interest with regard to Ibrahim's personality and his system in Syria is preserved in the British Foreign Office archives; for references to these see *Cambridge Mod. Hist.* x. 852, bibliography to chap. xvii.

IBSEN, HENRIK (1828–1906), Norwegian dramatic and lyric poet, eldest son of Knud Henriksen Ibsen, a merchant, and of his wife Marichen Cornelia Altenburg, was born at Skien on the 20th of March 1828. For five generations the family had consisted on the father's side of a blending of the Danish, German and Scottish races, with no intermixture of pure Norwegian. In 1836 Knud Ibsen became insolvent, and the family withdrew, in great poverty, to a cottage in the outskirts of the town. After brief schooling at Skien, Ibsen was, towards the close of 1843, apprenticed to an apothecary in Grimstad; here he remained through seven dreary years of drudgery, which set their mark upon his spirit. In 1847, in his nineteenth year, he began to write poetry. He made a gloomy and almost sinister impression upon persons who met him at this time, and one of his associates of those days has recorded that Ibsen "walked about Grimstad like a mystery sealed with seven seals." He had continued, by assiduous reading, his self-education, and in 1850 he contrived to come up as a student to Christiania. In the same year he published his first work, the blank-verse tragedy of *Catilina*, under the pseudonym Brynjolf Bjarme. A second drama, *The Viking's Barrow*, was acted (but not printed) a few months later; Ibsen was at this time entirely under the influence of the Danish poet Oehlenschläger. During the next year or two he made a very precarious livelihood in Christiania as a journalist, but in November 1851 he had the good fortune to be appointed "stage-poet" at the little theatre of Bergen, with a small but regular salary. He was practically manager at this house, and he also received a travelling stipend. In 1852, therefore, he went for five months to study the stage, to Copenhagen and to Dresden. Among many dramatic experiments which Ibsen made in Bergen, the most considerable and most satisfactory is the saga-drama of *Mistress Inger at Östraat*, which was produced in 1855; and printed at Christiania in 1857; here are already perceptible some qualities of his mature character. Much less significant, although at the time more successful, is *The Feast at Solhaug*, a tragedy produced in Bergen in 1856; here for a moment Ibsen abandoned his own nascent manner for an imitation of the popular romantic dramatist of Denmark, Henrik Hertz. It is noticeable that Ibsen, by far the most original of modern writers for the stage, was remarkably slow in discovering the true bent of his genius. His next dramatic work was the romantic tragedy of *Olaf Liljekrans*, performed in 1857, but unprinted until 1898. This was the last play Ibsen wrote in Bergen. In the summer of the former year his five years' appointment came to an end, and he returned to Christiania. Almost immediately he began the composition of a work which showed an extraordinary advance on all that he had written before, the beautiful saga-drama of *The Warriors in Helgeland*, in which he threw off completely the influence of the Danish romantic tragedians, and took his material directly from the ancient Icelandic sources. This play marks an epoch in the development of Norwegian literature. It was received by the managers, both in Christiania and Copenhagen, with contemptuous disapproval, and in the autumn of 1857 Ibsen could not contrive to produce it even at the new theatre of which he was now the manager. *The Warriors* was printed at Christiania in 1858, but was not acted anywhere until 1861. During these years Ibsen suffered many reverses and humiliations, but he persisted in his own line in art. Some of his finest short poems, among others the admirable seafaring romance, *Terje Vigen*, belong to the year 1860. The annoyances which Ibsen suffered, and the retrograde and ignorant conditions which he felt around him in Norway, developed the ironic qualities in his genius, and he became an acid satirist. The brilliant rhymed drama, *Love's Comedy*, a masterpiece of lyric wit and incisive vivacity, was published in 1862. This was a protest against the conventionality which deadens the beauty of all the formal relations between men and women, and against the pettiness, the publicity, and the prosiness of betrothed and married life among the middle classes in Norway; it showed how society murders the poetry of love. For some time past Ibsen had been meditating another saga-drama in prose, and in 1864 this appeared, *Kongsemnerne* (The Pretenders). These works, however, now so universally admired, contained an element of strangeness which was not welcome when they were new. Ibsen's position in Christiania grew more and more disagreeable, and he had positive misfortunes which added to his embarrassment. In 1862 his theatre became bankrupt, and he was glad to accept the poorly-paid post of "aesthetic adviser" at the other house. An attempt to obtain a poet's pension (*digtergage*) was unsuccessful; the Storthing, which had just voted one to Björnson, refused to do the same for Ibsen. His cup was full of disillusion and bitterness, and in April 1864 he started, by Berlin and Trieste, ultimately to settle in Rome. His anger and scorn gave point to the satirical arrows which he shot back to his thankless fatherland from Italy in the splendid poem of *Brand*, published in Copenhagen in 1866, a fierce attack on the Laodicean state of religious and moral sentiment in the Norway of that day; the central figure, the stern priest Brand, who attempts to live like Christ and is snubbed and hounded away by his latitudinarian companions, is one of the finest conceptions of a modern poet. Ibsen had scarcely closed *Brand* before he started a third lyrico-dramatic satire, *Peer Gynt* (1867), which remains, in a technical sense, the most highly finished of all his metrical works. In *Brand* the hero had denounced certain weaknesses which Ibsen saw in the Norwegian character, but these and other faults are personified in the hero of *Peer Gynt*; or rather, in this figure the poet pictured, in a type, the Norwegian nation in all the egotism, vacillation, and lukewarmness which he believed to be characteristic of it. Ibsen, however, acted better than he preached, and he soon forgot his abstraction in the portrait of Peer Gynt as a human individual. In this magnificent work modern Norwegian literature first rises to a level with the finest European poetry of the century. In 1869 Ibsen wrote the earliest of his prose dramas, the political comedy, *The Young Men's League*, in which for the first time he exercised his extraordinary gift for perfectly natural and yet pregnant dialogue. Ibsen was in Egypt, in October 1869, when his comedy was put on the stage in Christiania, amid violent expressions of hostility; on hearing the news, he wrote his brilliant little poem of defiance, called *At Port Saïd*. By this time, however, he had become a successful author; *Brand* sold largely, and has continued to be the most popular of Ibsen's writings. In 1866, moreover, the Storthing had been persuaded to vote him a "poet's pension," and there was now an end of Ibsen's long struggle with poverty. In 1868 he left Rome, and settled in Dresden until 1874, when he returned to Norway. But after a short visit he went back to Germany, and lived first at Dresden, afterwards at Munich, and did not finally settle in Christiania until 1891. His shorter lyrical poems were collected in 1871, and in that year his name and certain of his writings were for the first time mentioned to the English public. At this time he was revising his old works, which were out of print, and which he would not resign again to the reading world until he had subjected them to what in some instances (for example, *Mistress Inger at Östraat*) amounted to practical recomposition. In 1873 he published a double drama, each part of which was of unusual bulk, the whole forming the tragedy of *Emperor and Galilean*; this, Ibsen's latest historical play, has for subject the unsuccessful struggle of Julian the Apostate to hold the world against the rising tide of Christianity. The work is of an experimental kind, and takes its place between the early poetry and the later prose of the author. Compared with the series of plays which Ibsen had already inaugurated with *The Young Men's League, Emperor and Galilean* preserves a colour of idealism and even of mysticism which was for many years to be absent from Ibsen's writings, but to reappear in his old age with *The Master-builder*. There is some foundation for the charge that Ibsen has made his romantic Greek emperor needlessly squalid, and that he has robbed him, at last, too roughly of all that made him a sympathetic exponent of Hellenism. Ibsen was now greatly occupied by the political spectacle of Germany at war first in Denmark, then in France, and he believed that all things were conspiring to start a new epoch of individualism. He was therefore deeply disgusted by the Paris commune, and disappointed by the conservative reaction which succeeded it. This disillusion in political matters had a very direct influence upon Ibsen's literary work. It persuaded him that nothing could be expected in the way of reform from democracies, from large blind masses of men moved capriciously in any direction, but that the sole hope for the future must lie in the study of personality, in the development of individual character. He set himself to diagnose the conditions of society, which he had convinced himself lay sick unto death. Hitherto Ibsen had usually employed rhymed verse for his dramatic compositions, or, in the case of his saga-plays, a studied and artificial prose. Now, in spite of the surprising achievements of his poetry, he determined to abandon versification, and to write only in the language of everyday conversation. In the first drama of this his new period, *The Pillars of Society* (1877), he dealt with the problem of hypocrisy in a small commercial centre of industry, and he drew in the Bernick family a marvellous picture of social egotism in a prosperous seaport town. There was a certain similarity between this piece and *A Doll's House* (1879), although the latter was much the more successful in awakening curiosity. Indeed, no production of Ibsen's has been so widely discussed as this, which is nevertheless not the most coherently conceived of his plays. Here also social hypocrisy, was the object of the playwright's satire, but this time mainly in relation to marriage. In *A Doll's House* Ibsen first developed his views with regard to the individualism of woman. In his previous writings he had depicted woman as a devoted and willing sacrifice to man; here he begins to explain that she has no less a duty to herself, and must keep alive her own conception of honour and of responsibility. The conclusion of *A Doll's House* was violently and continuously discussed through the length and breadth of Europe, and to the situation of Nora Helmer is probably due more than to anything else the long tradition that Ibsen is "immoral." He braved convention still more audaciously in *Ghosts* (1881), perhaps the most powerful of the series of plays in which Ibsen diagnoses the diseases of modern society. It was received in Norway with a tumult of ill-will, and the author was attacked no less venomously than he had been twenty years before. Ibsen was astonished and indignant at the reception given to *Ghosts*, and at the insolent indifferentism of the majority to all ideas of social reform. He wrote, more as a pamphlet than as a play, what is yet one of the most effective of his comedies, *An Enemy of the People* (1882). Dr Stockmann, the hero of that piece, discovers that the drainage system of the bathing-station on which the little town depends is faulty, and the water impure and dangerous. He supposes that the corporation will be grateful to have these deficiencies pointed out; on the contrary, they hound him out of their midst as an "enemy of the people." In this play occurs Ibsen's famous and typical saying, "a minority may be right—a majority is always wrong." This polemical comedy seemed at first to be somewhat weakened by the personal indignation which runs through it, but it has held the stage. Ibsen's next drama, *The Wild Duck* (1884), was written in singular contrast with the zest and fire which had inspired *An Enemy of the People*. Here he is squalid and pessimistic to a degree elsewhere unparalleled in his writings; it is not quite certain that he is not here guilty of a touch of parody of himself. The main figure of the play is an unhealthy, unlucky enthusiast, who goes about making hopeless mischief by exposing weak places in the sordid subterfuges of others. This drama contains a figure, Hjalmar Ekdal, who claims the bad pre-eminence of being the meanest scoundrel in all drama. *The Wild Duck* is the darkest, the least relieved, of Ibsen's studies of social life, and his object in composing it is not obvious. With *Rosmersholm* (1886) he rose to the height of his genius again; this is a mournful, but neither a pessimistic nor a cynical play. The fates which hang round the contrasted lives of Rosmer and Rebecca, the weak-willed scrupulous man and the strong-willed unshrinking woman, the old culture and the new, the sickly conscience and the robust one, create a splendid dramatic antithesis. Ibsen then began to compose a series of dramas, of a more and more symbolical and poetic character; the earliest of these was the mystical *The Lady from the Sea* (1888). At Christmas 1890 he brought out *Hedda Gabler*; two years later *The Master-builder* (*Bygmester Solnaes*), in which many critics see the highest attainment of his genius; at the close of 1894 *Little Eyolf*; in 1896 *John Gabriel Borkman*; and in 1900 *When We Dead Awaken*. On the occasion of his seventieth birthday (1898) Ibsen was the recipient of the highest honours from his own country and of congratulations and gifts from all parts of the world. A colossal bronze statue of him was erected outside the new National Theatre, Christiania, in September 1899. In 1901 his health began to decline, and he was ordered by the physician to abandon every species of mental effort. The evil advanced, and he became unconscious of the passage of events. After lingering in this sad condition he died, without suffering, on the 23rd of May 1906, and was accorded a public funeral, with the highest national honours.

No recent writer belonging to the smaller countries of Europe has had so widely spread a fame as that of Ibsen, and although the value of his dramatic work is still contested, it has received the compliment of vivacious discussion in every part of the world. There would, perhaps, have been less violence in this discussion if it had been perceived that the author does not pose as a moral teacher, but as an imaginative investigator. He often and with much heat insisted that he was not called upon as a poet to suggest a remedy for the diseases of society, but to diagnose them. In this he was diametrically opposed to Tolstoi, who admitted that he wrote his books for the healing of the nations. If the subjects which Ibsen treats, or some of them, are open to controversy, we are at least on firm ground in doing homage to the splendour of his art as a playwright. He reintroduced into modern dramatic literature something of the velocity and inevitability of Greek tragic intrigue. It is very rarely that any technical fault can be found with the architecture of his plots, and his dialogue is the most lifelike that the modern stage has seen. His long apprenticeship to the theatre was of immense service to him in this respect. In every country, though least perhaps in England, the influence of Ibsen has been marked in the theatrical productions of the younger school. Even in England, on the rare occasions when his dramas are acted, they awaken great interest among intelligent playgoers.

The editions of Ibsen's works are numerous, but the final text is included in the *Samlede Vaerker*, with a bibliography by J. B. Halvorsen, published in Copenhagen, in 10 vols. (1898–1902). They have been translated into the principal European languages, and into Japanese. The study of Ibsen in English was begun by Mr Gosse in 1872, and continued by Mr William Archer, whose version of Ibsen's prose dramas appeared in 5 vols. (1890, 1891; new and revised edition, 1906). Other translators have been Mr C. Herford, Mr R. A. Streatfield, Miss Frances Lord and Mr Adie. His *Correspondence* was edited, in 2 vols., under the supervision of his son, Sigurd Ibsen, in 1904 (Eng. trans., 1905). Critical studies on the writings and position of Ibsen are innumerable, and only those which were influential in guiding opinion, during the early part of his career, in the various countries, can be mentioned here: Georg Brandes *Aesthetiske Studier* (Copenhagen, 1868); Les Quesnel, *Poésie scandinave* (Paris 1874); Valfrid Valsenius, *Henrik Ibsen* (Helsingfors, 1879); Edmund Gosse, *Studies in Northern Literature* (London, 1879); L. Passarge, *Henrik Ibsen* (Leipzig, 1883); G. Brandes, *Björnson och Ibsen* (Stockholm, 1882); Henrik Jaeger, *Henrik Ibsen 1828–1888* (Copenhagen, 1888; Eng. trans., 1890); T. Terwey, *Henrik Ibsen* (Amsterdam, 1882); G. Bernard Shaw, *The Quintessence of Ibsen* (London, 1892). In France Count Moritz Prozor carried on an ardent propaganda in favour of Ibsen from 1885, and Jules Lemaître's articles in his *Les Contemporains* and *Impressions de théâtre* did much to encourage discussion. W. Archer forwarded the cause in England from 1878 onwards. In Germany Ibsen began to be known in 1866, when John Grieg, P. F. Siebold and Adolf Strodtmann successively drew attention to his early dramas; but his real popularity among the Germans dates from 1880. (E. G.)

IBYCUS, of Rhegium in Italy, Greek lyric poet, contemporary of Anacreon, flourished in the 6th century B.C. Notwithstanding his good position at home, he lived a wandering life, and spent a considerable time at the court of Polycrates, tyrant of Samos. The story of his death is thus related: While in the neighbourhood of Corinth, the poet was mortally wounded by robbers. As he lay dying he saw a flock of cranes flying overhead, and called upon them to avenge his death. The murderers betook themselves to Corinth, and soon after, while sitting in the theatre, saw the cranes hovering above. One of them, either in alarm or jest, ejaculated, "Behold the avengers of Ibycus," and thus gave the clue to the detection of the crime (Plutarch, *De Garrulitate*, xiv.). The phrase, "the cranes of Ibycus," passed into a proverb among the Greeks for the discovery of crime through divine intervention. According to Suidas, Ibycus wrote seven books of lyrics, to some extent mythical and heroic, but mainly erotic (Cicero, *Tusc. Disp.* iv. 33), celebrating the charms of beautiful youths and girls. F. G. Welcker suggests that they were sung by choruses of boys at the "beauty competitions" held at Lesbos. Although the metre and dialect are Dorian, the poems breathe the spirit of Aeolian melic poetry.

The best editions of the fragments are by F. W. Schneidewin (1833) and Bergk, *Poëtae lyrici Graeci*.

ICA (YCA, or ECCA), a city of southern Peru and the capital of a department of the same name, 170 m. S.S.E. of Lima, and 46 m. by rail S.E. of Pisco; its port on the Pacific coast. Pop. (1906, official estimate) 6000. It lies in a valley of the foothills of the Cordillera Occidental, which is watered by the Rio de Ica, is made highly fertile by irrigation, and is filled with vineyards and cotton fields; between this valley and the coast is a desert. The original town was founded in 1563, 4 m. E. of its present site, but it was destroyed by the earthquake of 1571, and again by that of 1664, after which the present town was laid out near the ruins. In 1882 a Chilean marauding expedition inflicted great damage to private property in the town and vicinity. These repeated disasters give the place a partially ruined appearance, but it has considerable commercial and industrial prosperity. It has a large cotton factory and there are some smaller industries. Wine-making is one of the principal industries of the valley, and much brandy, called *pisco*, is exported from Pisco. A new industry is that of drying the fruits for which this region is celebrated. Ica is the seat of a national college.

The department of ICA lies between the Western Cordillera and the Pacific coast, and extends from the department of Lima S.E. to that of Arequipa. Pop. (1906, official estimate) 68,220; area 8721 sq. m. Ica is in the rainless region of Peru, and the greater part of its surface is barren. It is crossed by the rivers Pisco, Ica and Grande, whose tributaries drain the western slope of the Cordillera, and whose valleys are fertile and highly cultivated. The valley of the Nasca, a tributary of the Grande, is celebrated for an extensive irrigating system constructed by the natives before the discovery of America. The principal products of the department are cotton, grapes, wine, spirits, sugar and fruit. These are two good ports on the northern coast, Tambo de Mora and Pisco, the latter being connected with the capital by a railway across the desert, 46 m. long.

ICE (a word common to Teutonic languages; cf. Ger. *Eis*), the solid crystalline form which water assumes when exposed to a sufficiently low temperature. It is a colourless crystalline substance, assuming forms belonging to the hexagonal system, and distinguished by a well-marked habit of twinning, which occasions the beautiful "ice flowers" displayed by hoar-frost. It is frequently precipitated as hoar-frost, snow or hail; and in the glaciers and snows of lofty mountain systems or of regions of high latitude it exists on a gigantic scale, being especially characteristic of the seas and lands around the poles. In various regions, especially in France and Italy, great quantities of ice form in caves, which, in virtue of their depth below the earth's surface, their height above the sea-level, or their exposure to suitable winds, or to two or more of these conditions in combination, are unaffected by ordinary climatic changes, so that the mean annual temperature is sufficiently low to ensure the permanency of the ice. The temperature at which water freezes, and also at which ice melts, is so readily determined that it is employed as one of the standard temperatures in the graduation of ordinary thermometer scales, this temperature being the zero of the Centigrade and Réaumur scales, and 32° of the Fahrenheit (see THERMOMETRY). In the act of freezing, water, though its temperature remains unchanged, undergoes a remarkable expansion so that ice at 0° C. is less dense than water—a fact demonstrated by its power of floating. The sub-aqueous retention of "ground-ice" or "anchor-ice," which forms in certain circumstances at the bottom of streams or pools in which there are many eddies, is due to the cohesion between it and the stones or rocks which compose the bed of the streams or pools. As water expands on freezing, so conversely ice contracts on melting; and the ice-cold water thus formed continues to contract when heated until it has reached its point of maximum density, the temperature at which this occurs being about 39° Fahr. or 4° C. Above this point water continuously expands, and at no temperature is it less dense than ice as is shown by the following table:—

Density of ice at		0°C. =	·9175
,,	water at	0°C. =	·99988
,,	,,	4°C. =	1·00000
,,	,,	10°C. =	·99976
,,	,,	100°C. =	·95866

Under the influence of heat, ice itself behaves as most solids do, contracting when cooled, expanding when heated. According to Plücker, the coefficient of cubical dilatation at moderately low temperatures is 0·0001585. From a series of elaborate experiments, Person deduced 0·505 as the specific heat of ice, or about half that of water.

Though no rise of temperature accompanies the melting of ice, there is yet a definite quantity of heat absorbed, namely, about 80 calories per gram; this is called the latent heat of fusion of water (see FUSION). The same amount of heat is evolved when water becomes ice. That ice can be melted by increase of pressure was first pointed out by James Thomson in 1849. He showed that, since water expands on freezing, the laws of thermodynamics require that its freezing-point must be lowered by increase of pressure; and he calculated that for every additional atmosphere of pressure the freezing-point of water was lowered by 0·0075°. This result was verified by his brother, Sir William Thomson (Lord Kelvin), in 1850. The Thomsons and H. L. F. Helmholtz successfully applied this behaviour of ice under pressure to the explanation of many properties of the substance. When two blocks of ice at 0° C. are pressed together or even simply laid in contact, they gradually unite along their touching surfaces till they form one block. This "regelation" is due to the increased pressure at the various points of contact causing the ice there to melt and cool. The water so formed tends to escape, thus relieving the pressure for an instant, refreezing and returning to the original temperature. This succession of melting and freezing, with their accompanying thermal effects, goes on until the two blocks are cemented into one.

Ice forms over fresh water if the temperature of the air has been for a sufficient time at or below the freezing-point; but not until the whole mass of water has been cooled down to its point of maximum density, so that the subsequent cooling of the surface can give rise to no convection currents, is freezing possible. Sea-water, in the most favourable circumstances, does not freeze till its temperature is reduced to about −2° C.; and the ice, when formed, is found to have rejected four-fifths of the salt which was originally present. In the upper provinces of India water is made to freeze during cold clear nights by leaving it overnight in porous vessels, or in bottles which are enwrapped in moistened cloth. The water then freezes in virtue of the cold produced by its own evaporation or by the drying of the moistened wrapper. In Bengal the natives resort to a still more elaborate forcing of the conditions. Pits are dug about 2 ft. deep and filled three-quarters full with dry straw, on which are set flat porous pans containing the water to be frozen. Exposed overnight to a cool dry gentle wind from the north-west, the water evaporates at the expense of its own heat, and the consequent cooling takes place with sufficient rapidity to overbalance the slow influx of heat from above through the cooled dense air or from below through the badly conducting straw.

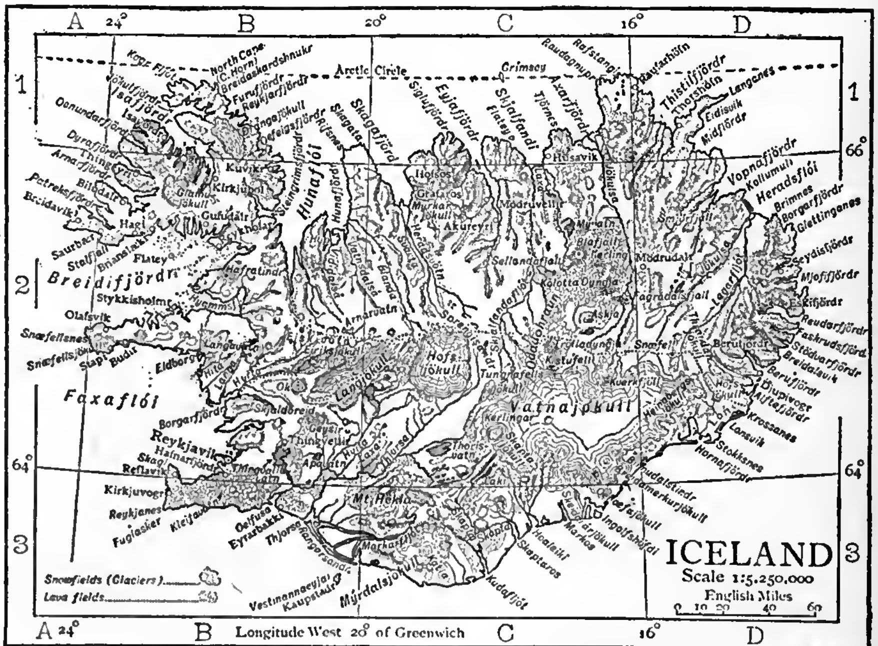
See WATER, and for the manufacture of ice see REFRIGERATING.

ICEBERG (from ice and *Berg*, Ger. for hill, mountain), a floating mass of ice broken from the end of a glacier or from an ice-sheet. The word is sometimes, but rarely, applied to the arch of an Arctic glacier viewed from the sea. It is more commonly used to describe huge floating masses of ice that drift from polar regions into navigable waters. They are occasionally encountered far beyond the polar regions, rising into beautiful forms with breakers roaring into their caves and streams of water pouring from their pinnacles in the warmer air. When, however, they rest in comparatively warm water, melting takes place most rapidly at the base and they frequently overturn. Only one-ninth of the mass of ice is seen above water. When a glacier descends to the sea, as in Alaska, and "advances into water, the depth of which approaches its thickness, the ends are broken off and the detached masses float away as icebergs. Many of the bergs are overturned, or at least tilted, as they set sail. If this does not happen at once it is likely to occur later as the result of the wave-cutting and melting which disturb their equilibrium" (T. C. Chamberlin and R. D. Salisbury, *Geology: Processes and their Results*, 1905). These bergs carry a load of débris from the glacier and gradually strew their load upon the sea floor. They do not travel far before losing all stony and earthy débris, but glacial material found in dredgings shows that icebergs occasionally carry their load far from land. The structure of the iceberg varies with its origin and is always that of the glacier or ice-sheet from which it was broken. The breaking off of the ice-sheet from a Greenland glacier is called locally the "calving" of the glacier. The constantly renewed material from which the icebergs are formed is brought down by the motion of the glacier. The ice-sheet cracks at the end, and masses break off, owing to the upward pressure of the water upon the lighter ice which is pushed into it. This is accomplished with considerable violence. The disintegration of an Arctic ice-sheet is a simpler matter, as the ice is already floating.

ICELAND (Dan. *Island*), an island in the North Atlantic Ocean, belonging to Denmark. Its extreme northerly point is touched by the Arctic Circle; it lies between 13° 22′ and 24° 35′ W., and between 63° 12′ and 66° 33′ N., and has an area of 40,437 sq. m. Its length is 298 m. and its breadth 194 m., the shape being a rough oval, broken at the north-west, where a peninsula, diversified by a great number of fjords, projects from the main portion of the island. The total length of the coast-line is about 3730 m., of which approximately one-third belongs to the north-western peninsula. Iceland is a plateau or tableland, built up of volcanic rocks of older and younger formation, and pierced on all sides by fjords and valleys. Compared with the tableland, the lowlands have a relatively small area, namely, one-fourteenth of the whole; but these lowlands are almost the only parts of the island which are inhabited. In consequence of the rigour of its climate, the central tableland is absolutely uninhabitable. At the outside, not more than one-fourth of the area of Iceland is inhabited; the rest consists of elevated deserts, lava streams and glaciers. The north-west peninsula is separated from the main mass of the island by the bays Hunaflói and Breiðifjörðr, so that there are really two tablelands, a larger and a smaller. The isthmus which connects the two is only $4\frac{1}{4}$ m. across, but has an altitude of 748 ft. The mean elevation of the north-west peninsula is 2000 ft. The fjords and glens which cut into it are shut in by precipitous walls of basalt, which plainly shows that they have been formed by erosion through the mass of the plateau. The surface of this tableland is also bare and desolate, being covered with gravel and fragments of rock. Here and there are large straggling snowfields, the largest being Glámu and Drangajökull,[1] on the culminating points of the plateau. The only inhabited districts are the shores of the fjords, where grass grows capable of supporting sheep; but a large proportion of the population gain their livelihood by fishing. The other and larger tableland, which constitutes the substantial part of Iceland, reaches its culminating point in the south-east, in the gigantic snowfield of Vatnajökull, which covers 3300 sq. m. The axis of highest elevation of Iceland stretches from north-west to south-east, from the head of Hvammsfjörðr to Hornafjörðr, and from this water-parting the rivers descend on both sides. The crest of the water-parting is crowned by a chain of snow-capped mountains, separated by broad patches of lower ground. They are really a chain of minor plateaus which rise 4500 to 6250 ft. above sea-level and 2000 to 3000 ft. above the tableland itself. In the extreme east is Vatnajökull, which is separated from Tungnafellsjökull by Vonarskard (3300 ft.). Between Tungnafellsjökull and Hofsjökull lies the broad depression of Sprengisandr (2130 ft.). Continuing north-west, between Hofsjökull and the next snow-capped mountain, Langjökull, lies Kjölur (2000 ft.); and between Langjökull and Eiriksjökull, Flosaskard (2630 ft.). To the north of the *jöklar* last mentioned there are a number of lakes, all well stocked with fish. Numerous valleys or glens penetrate into the tableland, especially on the north and east, and between them long mountain spurs, sections of the tableland which have resisted the action of erosion, thrust themselves towards the sea. Of these the most considerable is the mass crowned by Mýrdalsjökull, which stretches towards the south. The interior of the tableland consists for the most part of barren, grassless deserts, the surface being covered by gravel, loose fragments of rock, lava, driftsand, volcanic ashes and glacial detritus.

Save the lower parts of the larger glens, there are no lowlands on the north and east. The south coast is flat next the sea; but immediately underneath Vatnajökull there is a strip of gravel and sand, brought down and deposited by the glacial streams. The largest low-lying plain of Iceland, lying between Mýrdalsjökull and Reykjanes, has an area of about 1550 sq. m. In its lowest parts this plain barely keeps above sea-level, but it rises gradually towards the interior, terminating in a ramification of valleys. Its maximum altitude is attained at 381 ft. near Geysir. On the west of Mount Hekla this plain connects by a regular slope directly with the tableland, to the great injury of its inhabited districts, which are thus exposed to the clouds of pumice dust and driftsand that cover large areas of the interior. Nevertheless the greater part of this lowland plain produces good grass, and is relatively well inhabited. The plain is drained by three rivers—Markarfljót, Thjórsá and Oelfusá—all of large volume, and numerous smaller streams. Towards the west there exist a number of warm springs. There is another lowland plain around the head of Faxaflói, nearly 400 sq. m. in extent. As a rule the surface of this second plain is very marshy. Several dales or glens penetrate the central tableland; the eastern part of this lowland is called Borgarfjörðr, the western part Mýrar.

The great bays on the west of the island (Faxaflói and Breiðifjörðr),[2] as well as the many bays on the north, which are



¹ *Jökull*, plural *jöklar*, Icel. snowfield, glacier.
² *Flói*, bay; *fjörðr*, fjord.

separated from one another by rocky promontories, appear to owe their origin to subsidences of the surface; whereas the fjords of the north-west peninsula, which make excellent harbours, and those of the east coast seem to be the result chiefly of erosion.

Glaciers.—An area of 5170 sq. m. is covered with snowfields and glaciers. This extraordinary development of ice and snow is due to the raw, moist climate, the large rainfall and the low summer temperature. The snow-line varies greatly in different parts of the island, its range being from 1300 to 4250 ft. It is highest on the tableland, on the north side of Vatnajökull, and lowest on the north-west peninsula, to the south of North Cape. Without exception the great *névés* of Iceland belong to the interior tableland. They consist of slightly rounded domes or billowy snowfields of vast thickness. In external appearance they bear a closer resemblance to the glaciers of the Polar regions than to those of the Alps. The largest snowfields are Vatnajökull (3280 sq. m.), Hofsjökull (520) Langjökull (500) and Mýrdalsjökull (390). The glaciers which stream off from these snowfields are often of vast extent, *e.g.* the largest glacier of Vatnajökull has an area of 150 to 200 sq. m., but the greater number are small. Altogether, more than 120 glaciers are known in Iceland. It is on the south side of Vatnajökull that they descend lowest; the lower end of Breidamerkurjökull was in the year 1894 only 30 ft. above sea-level. The glaciers of the north-west peninsula also descend nearly to sea-level. The great number of streams of large volume is due to the moist climate and the abundance of glaciers, and the milky white or yellowish-brown colour of their waters (whence the common name Hvítá, white) is due to the glacial clays. The majority of them change their courses very often, and vary greatly in volume; frequently they are impetuous torrents, forming numerous waterfalls. Iceland also possesses a great number of lakes, the largest being Thingvallavatn[3] and Thorisvatn, each about 27 sq. m. in area. Mývatn, in the north, is well known from the natural beauty of its surroundings. Above its surface tower a great number of volcanoes and several craters, and its waters are alive with water-fowl, a multitude of ducks of various species breeding on its islands. The lakes of Iceland owe their origin to different causes, some being due to glacial erosion, others to volcanic subsidence. Mývatn fills a depression between lava streams, and has a depth of not more than $8\frac{3}{4}$ ft. The group of lakes called Fiskivötn (or Veidivötn), which lie in a desolate region to the west of Vatnajökull, consist for the most part of crater lakes. The groups of lakes which lie north-west from Langjökull occupy basins formed between ridges of glacial gravel; and in

³ *Vatn*, lake.

the valleys numerous lakes are found at the backs of the old moraines.

Volcanoes.—Iceland is one of the most volcanic regions of the earth; volcanic activity has gone on continuously from the formation of the island in the Tertiary period down to the present time. So far as is known, there have in historic times been eruptions from twenty-five volcanic vents. Altogether 107 volcanoes are known to exist in Iceland, with thousands of craters, great and small. The lava-streams which have flowed from them since the Glacial epoch now cover an area of 4650 sq. m. They are grouped in dense masses round the volcanoes from which they have flowed, the bulk of the lava dating from outbreaks which occurred in prehistoric times. The largest volume of lava which has issued at one outflow within historic times is the stream which came from the craters of Laki at Skaptá. This belongs to the year 1783, and covers an area of 218 sq. m., and amounts to a volume represented by a cube each of whose sides measures $7\frac{1}{2}$ m. The largest unbroken lava-field in Iceland is Odaðahraun (Lava of Evil Deeds), upon the tableland north from Vatnajökull (2000 to 4000 ft. above sea-level). It is the accretion of countless eruptions from over twenty volcanoes, and covers an area of 1300 sq.m. (or, including all its ramifications and minor detached streams, 1700 sq. m.), and its volume would fill a cube measuring 13·4 m. in every direction. As regards their superficies, the lava-streams differ greatly. Sometimes they are very uneven and jagged (*apalhraun*), consisting of blocks of lava loosely flung together in the utmost confusion. The great lava-fields, however, are composed of vast sheets of lava, ruptured and riven in divers ways (*helluhraun*). The smooth surface of the viscous billowy lava is further diversified by long twisted "ropes," curving backwards and forwards up and down the undulations. Moreover, there are gigantic fissures, running for several miles, caused by subsidences of the underlying sections. The best-known fissure of this character is Almannagjá at Thingvellir. On the occasion of outbreaks the fine ashes are scattered over a large portion of the island, and sometimes carried far across the Atlantic. After the eruption of Katla in 1625 the ashes were blown as far as Bergen in Norway, and when Askja was in eruption in 1875 a rain of ashes fell on the west coast of Norway 11 hours 40 minutes, and at Stockholm 15 hours, afterwards. The volcanic ash frequently proves extremely harmful, destroying the pastures so that the sheep and cattle die of hunger and disease. The outbreak of Laki in 1783 occasioned the loss of 11,500 cattle, 28,000 horses and 190,500 sheep—that is to say, 53% of the cattle in the island, 77% of the horses and 82% of the sheep. After that the island was visited by a famine, which destroyed 9500 people, or one-fifth of the total population.

The Icelandic volcanoes may be divided into three classes: (1) cone-shaped, like Vesuvius, built up of alternate layers of ashes, scoriae and lava; (2) cupola-shaped, with an easy slope and a vast crater opening at the top—these shield-shaped cupolas are composed entirely of layers of lava, and their inclination is seldom steeper than 7°-8° ; (3) chains of craters running close alongside a fissure in the ground. For the most part the individual craters are low, generally not exceeding 300 to 500 ft. These crater chains are both very common and often very long. The chain of Laki, which was formed in 1783, extends 20 m., and embraces about one hundred separate craters. Sometimes, however, the lava-streams are vomited straight out of gigantic fissures in the earth without any crater being formed. Many of the Icelandic volcanoes during their periods of quiescence are covered with snow and ice. Then when an outbreak occurs the snow and ice melt, and in that way they sometimes give rise to serious catastrophes (*jökulhlaup*), through large areas being suddenly inundated by great floods of water, which bear masses of ice floating on their surface. Katla caused very serious destruction in this way by converting several cultivated districts into barren wastes. In the same way in the year 1362 Oeræfajökull, the loftiest mountain in Iceland (6424 ft.), swept forty farms, together with their inhabitants and live stock, bodily into the ocean. The best-known volcano is Hekla (5108 ft.), which was in eruption eighteen times within the historic period down to 1845. Katla during the same period was active thirteen times down to 1860. The largest volcano is Askja, situated in the middle of the lava-field of Odaðahraun. Its crater measures 34 sq. m. in area. At Mývatn there are several volcanoes, which were particularly active in the years 1724–1730. On several occasions there have been volcanic outbreaks under the sea outside the peninsula of Reykjanes, islands appearing and afterwards disappearing again. The crater chain of Laki has only been in eruption once in historic times, namely, the violent and disastrous outbreak of 1783. Iceland, however, possesses no constantly active volcano. There are often long intervals between the successive outbreaks, and many of the volcanoes (and this is especially true of the chains of craters) have only vented themselves in a solitary outburst.

Earthquakes are frequent, especially in the districts which are peculiarly volcanic. Historical evidence goes to show that they are closely associated with three naturally defined regions: (1) the region between Skjálfandi and Axarfjörðr in the north, where violent earth tremblings are extremely common; (2) at Faxaflói, where minor vibrations are frequent; (3) the southern lowlands, between Reykjanes and Mýrdalsjökull, have frequently been devastated by violent earthquake shocks, with great loss of property and life, *e.g.* on the 14th-16th of August 1784, when 92 farmsteads were totally destroyed, and 372 farmsteads and 11 churches were seriously damaged; and again in August and September 1896, when another terrible earthquake destroyed 161 farmsteads and damaged 155 others. Hot springs are found in every part of Iceland, both singly and in groups; they are particularly numerous in the western portion of the southern lowlands, where amongst others is the famous Geyser (*q.v.*). Sulphur springs and boiling mud lakes are also general in the volcanic districts; and in places there are carbonic acid springs, these more especially on the peninsula of Snæfellsnes, north of Faxaflói.

Geology.—Iceland is built up almost entirely of volcanic rocks, none of them older, however, than the middle of the Tertiary period. The earlier flows were probably contemporaneous with those of Greenland, the Færoes, the western islands of Scotland and the north-east of Ireland. The principal varieties are basalt and palagonitic breccias, the former covering two-thirds of the entire area, the latter the remaining one-third. Compared with these two systems, all other formations have an insignificant development. The palagonitic breccias, which stretch in an irregular belt across the island, are younger than the basalt. In the north-west, north and east the coasts are formed of basalt, and rise in steep, gloomy walls of rock to altitudes of 3000 ft. and more above sea-level. Deposits of clay, with remains of plants of the Tertiary period, lignite and tree-trunks pressed flat, which the Icelanders call *surtarbrandur*, occur in places in the heart of the basalt formation. These fossiliferous strata are developed in greatest thickness in the north-west peninsula. Indeed, in some few places well-marked impressions of leaves and fruit have been discovered, proving that in Tertiary times Iceland possessed extensive forests, and its annual mean temperature must have been at least 48° Fahr., whereas the present mean is 35·6°. The palagonitic breccias, which attain their greatest development in the south of the island and on the tableland, consist of reddish, brown or yellowish rocks, tuffs and breccias, belonging to several different groups or divisions, the youngest of which seems to be of a date subsequent to the Glacial epoch. All over Iceland, in both the basalt and breccia formations, there occur small intrusive beds and dikes of liparite, and as this rock is of a lighter colour than the basalt, it is visible from a distance. In the south-east of the island, in the parish of Lón, there exist a few mountains of gabbro, a rock which does not occur in any other part of Iceland. Near Húsavik in the north there have been found marine deposits containing a number of marine shells; they belong to the Red Crag division of the Pliocene. In the middle of Iceland, where the geological foundation is tuff and breccias, large areas are buried under ancient outflows of lava, which bear evidences of glacial scratching. These lava streams, which are of a doleritic character, flowed before the Glacial age, or during its continuance, out of lava cones with gigantic crater openings, such as may be seen at the present day. During the Glacial epoch the whole of Iceland was covered by a vast sheet of inland ice, except for a few small isolated peaks rising along its outer margins. This ice-cap had on the tableland a thickness of 2300 to 2600 ft. Rocks scored by glacial ice and showing plain indications of striation, together with thousands of erratic blocks, are found scattered all over Iceland. Signs of elevation subsequent to the Glacial epoch are common all round the island, especially on the north-west peninsula. There are found strikingly developed marine terraces of gravel, shore lines and surf beaches marked on the solid rock. In several places there are traces of shells; and sometimes skeletal remains of whales and walruses, as well as ancient driftwood, have been discovered at tolerable distances from the present coast. The ancient shore-lines occur at two different altitudes. Along the higher, 230 to 260 ft. above the existing sea-level, shells have been found which are characteristic of high Arctic latitudes and no longer exist in Iceland; whereas on the lower shore-line, 100 to 130 ft., the shells belong to species which occur amongst the coast fauna of the present day.

The geysers and other hot springs are due to the same causes as the active volcanoes, and the earthquakes are probably manifestations of the same forces. A feature of special interest to geologists in the present conditions of the island is the great power of the wind both as a transporting and denuding agent. The rock sculpture is often very similar to that of a tropical desert.[1]

Climate.—Considering its high latitude and situation, Iceland has a relatively mild climate. The meteorological conditions vary greatly, however, in different parts of the island. In the south and east the weather is generally changeable, stormy and moist; whilst on the north the rainfall is less. The climate of the interior tableland approximates to the continental type and is often extremely cold. The mean annual temperature is 37·2° F. in Stykkishólmr on Breiðifjörðr, 38·3° at Eyrārbakki in the south of Iceland, 41° at Vestmannæyjar, 36° at Akureyri in the north, 36·7° on Berufjörðr in the east, and 30·6° at Mödrudalr on the central tableland. The range is great not only from year to year, but also from month to month. For instance, at Stykkishólmr the highest annual mean for March was 39·7°, and the lowest 8°, during a period of thirty-eight years. Iceland lies contiguous to that part of the north Atlantic in which the shifting areas of low pressure prevail, so that storms are frequent and the barometer is seldom firm. The barometric pressure at sea-level in the south-west of Iceland during the period 1878–1900 varied between 30·8 and 27·1 in. The climate of the coasts is relatively mild in summer, but tolerably cold in winter. The winter means of the north and east coasts average 31·7° and 31·3° F. respectively; the summer means, 42·8° and 44·6°; and the means of the year, 33·1° and 35·6°. The winter means of the south and west coasts average 32° and 31·7° respectively; the summer means, 48·2° and 50°; the annual means, 37·4° and 39·2°. The rainfall on the south and east coasts is considerable, *e.g.* at Vestmannæyjar, 49·4 in. in the year; at Berufjörðr, 43·6 in. On the west coast it is less, *e.g.* 24·3 in. at Stykkishólmr; but least of all on the north coast, being only 14·6 in. on the island of Grimsey, which lies off that coast. Mist is commonly prevalent on the east coast; at Berufjörðr there is mist on no fewer than 212 days in the year. The south and west coasts are washed by the Gulf Stream, and the north coast by an Arctic current, which frequently brings with it a quantity of drift-ice, and thus exercises a considerable effect upon the climate of the island; sometimes it blocks the north coast in the summer months. On the whole, during the 19th century, the north coast was free from ice on an average of one year in every four or five. The clearness of the atmosphere has been frequently remarked. Thunderstorms occur mostly in winter.

Flora.—The vegetation presents the characteristics of an Arctic European type, and is tolerably uniform throughout the island, the differences even on the tableland being slight. At present 435 species of phanerogams and vascular cryptogams are known; the lower orders have been little investigated. The grasses are of the greatest importance to the inhabitants, for upon them they are dependent for the keep of their live stock. Heather covers large tracts, and also affords pasture for sheep. The development of forest trees is insignificant. Birch woods exist in a good many places, especially in the warmer valleys; but the trees are very short, scarcely attaining more than 3 to 10 ft. in height. In a few places, however, they reach 13 to 20 ft. and occasionally more. A few mountain ash or rowan trees (*Sorbus aucuparia*) are found singly here and there, and attain to 30 ft. in height. Willows are also pretty general, the highest in growth being *Salix phyllicifolia*, 7 to 10 ft. The wild flora of Iceland is small and delicate, with bright bloom, the heaths being especially admired. Wild crowberries and bilberries are the only fruit found in the island.

Fauna.—The Icelandic fauna is of a sub-Arctic type. But while the species are few, the individuals are often numerous. The land mammals are very poorly represented; and it is doubtful whether any species is indigenous. The polar bear is an occasional visitant, being brought to the coast by the Greenland drift-ice. Foxes are common, both the white and the blue occurring; mice and the brown rat have been introduced, though one variety of mouse is possibly indigenous. Reindeer were introduced in 1770. The marine mammalia are numerous. The walrus is now seldom seen, although in prehistoric times it was common. There are numerous species of seals; and the seas abound in whales. Of birds there are over 100 species, more than one-half being aquatic. In the interior the whistling swan is common, and numerous varieties of ducks are found in the lakes. The eider duck, which breeds on the islands of Breiðifjörðr, is a source of livelihood to the inhabitants, as are also the many kinds of sea-fowl which breed on the sea-cliffs. Iceland possesses neither reptiles nor batrachians. The fish fauna is abundant in individuals, some sixty-eight species being found off the coasts. The cod fisheries are amongst the most important in the world. Large quantities of herring, plaice and halibut are also taken. Many of the rivers abound in salmon, and trout are plentiful in the lakes and streams.

Population and Towns.—The census of 1890 gave a total population of 70,927, and this number had increased by 1901 to 78,489. The increase during the 19th century was 27,000, while at least 15,600 Icelanders emigrated to America, chiefly to Manitoba, from 1872 to the close of the century. The largest town is Reykjavik on Faxaflói, with 6700 inhabitants, the capital of the island, and the place of residence of the governor-general and the bishop. Here the Althing meets; and here, further, are the principal public institutions of the island (library, schools, &c.). The town possesses a statue to Thorvaldsen, the famous sculptor, who was of Icelandic descent. The remaining towns include Isafjörðr (pop. 1000) on the north-west peninsula, Akureyri (1000) on the north and Seydisfjörðr (800) in the east.

Industries.—The principal occupation of the Icelanders is cattle-breeding, and more particularly sheep-breeding, although the fishing industries have come rapidly to the front in modern times. In 1850, 82% of the population were dependent upon cattle-breeding and 7% upon fishing; in 1890 the numbers were 64% and 18% respectively. The culture of grain is not practised in Iceland; all bread-stuffs are imported. In ancient times barley was grown in some places, but it never paid for the cost of cultivation. Cattle-breeding has declined in importance, while the number of sheep has increased. Formerly gardening was of no importance, but considerable progress has been made in this branch in modern times, as also in the cultivation of potatoes and turnips. Fruit-trees will not thrive; but black and red currants and rhubarb are grown, the last-named doing excellently. Iceland possesses four agricultural schools, one agricultural society, and small agricultural associations in nearly every district. The fisheries give employment to about 12,000 people. For the most part the fishing is carried on from open boats, notwithstanding the dangers of so stormy a coast. But larger decked vessels have come into increasing use. In summer the waters are visited by a great number of foreign fishermen, inclusive of about 300 fishing-boats from French ports, as well as by fishing-boats from the Faeroes and Norway, and steam trawlers from England. Excellent profit is made in certain parts of the island from the herring fishery; this is especially the case on the east coast. There are marine insurance societies and a school of navigation at Reykjavik. The export of fish and fish products has greatly increased. In 1849 to 1855 the annual average exported was 1480 tons; whereas at the close of the century (in 1899) it amounted to 11,339 tons and 68,079 barrels of oil, valued at £276,596.

Commerce.—From the first colonization of the island down to the 14th century the trade was in the hands of native Icelanders and Norsemen; in the 15th century it was chiefly in the hands of the English, in the 16th of Germans from the Hanse towns. From 1602 to 1786 commerce was a monopoly of the Danish government; in the latter year it was declared free to all Danish subjects and in 1854 free to all nations. Since 1874, when Iceland obtained her own administration, commerce has increased considerably. Thus the total value of the imports and exports together in 1849 did not exceed £170,000; while in 1891–1895 the imports averaged £356,000 and the exports £340,000. In

[1] See Th. Thoroddsen, "Explorations in Iceland during the years 1881–1898," *Geographical Journal*, vol. xiii. (1899), pp. 251–274, 480–513, with map.

1902 imports were valued at £596,193 and exports at £511,083. Trade is almost entirely with Denmark, the United Kingdom, and Norway and Sweden, in this order according to value. The principal native products exported are live sheep, horses, salt meat, wool and hides, to which must be added the fish products—cod, train-oil, herring and salmon—eiderdown and woollen wares. The spinning, weaving and knitting of wool is a widespread industry, and the native tweed (*vaðmal*) is the principal material for the clothing of the inhabitants. The imports consist principally of cereals and flour, coffee, sugar, ale, wines and spirits, tobacco, manufactured wares, iron and metal wares, timber, salt, coal, &c. The money, weights and measures in use are the same as in Denmark. The Islands Bank in Reykjavik (1904) is authorized to issue bank-notes up to £133,900 in total value.

Communications.—All land journeys are made on horseback, and in the remoter parts all goods have to be transported by the same means. Throughout the greater part of the island there exist no proper roads even in the inhabited districts, but only bridle-paths, and in the uninhabited districts not even these. Nevertheless much has been done to improve such paths as there are, and several miles of driving roads have been made, more particularly in the south. Since 1888 many bridges have been built; previous to that year there was none. The larger rivers have been spanned by iron swing-bridges, and the Blanda is crossed by a fixed iron bridge. Postal connexion is maintained with Denmark by steamers, which sail from Copenhagen and call at Leith. Besides, steamers go round the island, touching at nearly every port.

Religion.—The Icelanders are Lutherans. For ecclesiastical purposes the island is divided into 20 deaneries and 142 parishes, and the affairs of each ecclesiastical parish are administered by a parish council, and in each deanery by a district (*hjerað*) council. When a living falls vacant, the governor-general of the island, after consultation with the bishop, selects three candidates, and from these the congregation chooses one, the election being subsequently confirmed by the governor-general. In the case of certain livings, however, the election requires confirmation by the crown. In 1847 a theological seminary was founded at Reykjavik, and there the majority of the Icelandic ministry are educated; some, however, are graduates of the university of Copenhagen.

Health.—The public health has greatly improved in modern times; the death-rate of young children has especially diminished. This improvement is due to greater cleanliness, better dwellings, better nourishment, and the increase in the number of doctors. There are now doctors in all parts of the country, whereas formerly there were hardly any in the island. There is a modern asylum for leprosy at Laugarnes near Reykjavik, and a medical school at Reykjavik, opened in 1876. The general sanitary affairs of the island are under the control of a chief surgeon (national physician) who lives in Reykjavik, and has superintendence over the doctors and the medical school.

Government.—According to the constitution granted to Iceland in 1874, the king of Denmark shares the legislative power with the Althing, an assembly of 36 members, 30 of whom are elected by household suffrage, and 6 nominated by the king. The Althing meets every second year, and sits in two divisions, the upper and the lower. The upper division consists of the 6 members nominated by the king and 6 elected by the representatives of the people out of their own body. The lower division consists of the remaining 24 representative members. The minister for Iceland, who resided in Copenhagen until 1903, when his office was transferred to Reykjavik, is responsible to the king and the Althing for the maintenance of the constitution, and he submits to the king for confirmation the legislative measures proposed by the Althing. The king appoints a governor-general (*landshöfðingi*) who is resident in the island and carries on the government on the responsibility of the minister. Formerly Iceland was divided into four quarters, the east, the south, the west and north. Now the north and the east are united under one governor, and the south and the west under another. The island is further divided into 18 *sýslur* (counties), and these again into 169 hreppur (rapes) or poor-law districts. Responsible to the governors are the sheriffs (*sýslumenn*), who act as tax gatherers, notaries public and judges of first instance; the sheriff has in every *hreppur* an assistant, called *hreppstjóri*. In every *hreppur* there is also a representative committee, who administer the poor laws, and look after the general concerns of the *hreppur*. These committees are controlled by the committees of the *sýslur* (county boards), and these again are under the control of the *amtsráð* (quarter board), consisting of three members. From the sheriff courts appeals lie to the superior court at Reykjavik, consisting of three judges. Appeals may be taken in all criminal cases and most civil cases to the supreme court at Copenhagen.

Iceland has her own budget, the Althing having, by the constitution of 1874, the right to vote its own supplies. As the Althing only meets every other year, the budget is passed for two years at once. The total income and expenditure are each about £70,000 per financial period. There is a national reserve fund of about £60,000, but no public debt; nor is there any contribution for either military or naval purposes. Iceland has her own customs service, but the only import duties levied are upon spirits, tobacco, coffee and sugar, and in each case the duties are fairly low.

Education.—Education is pretty widespread amongst the people. In the towns and fishing villages there are a few elementary schools, but often the children are instructed at home; in some places by peripatetic teachers. It is incumbent upon the clergy to see that all children are taught reading, writing and arithmetic. The people are great readers; considering the number of the inhabitants, books and periodicals have a very extensive circulation. Eighteen newspapers are issued (once and twice a week), besides several journals, and Iceland has always been distinguished for her native literature. At Reykjavik there are a Latin school, a medical school and a theological school; at Mödruvellir and Hafnarfjörðr, modern high schools (*Realschulen*); and in addition to these there are four agricultural schools, a school of navigation, and three girls' schools. The national library at Reykjavik contains some 40,000 volumes and 3000 MSS. At the same place there is also a valuable archaeological collection. Amongst the learned societies are the Icelandic Literary Society (*Bokmentafjelag*), the society of the Friends of the People, and the Archaeological Society of Reykjavik.

HISTORY

Shortly after the discovery of Iceland by the Scandinavian, *c.* 850 (it had long been inhabited by a small colony of Irish Culdees), a stream of immigration set in towards it, which lasted for sixty years, and resulted in the establishment of some 4000 homesteads. In this immigration three distinct streams can be traced. (1) About 870–890 four great noblemen from Norway, Ingolf, Ketil Hæng, Skalla-Grim and Thorolf, settled with their dependants in the south-west of the new found land. (2) In 890–900 there came from the western Islands Queen Aud, widow of Olaf the White, king of Dublin, preceded and followed by a number of her kinsmen and relations (many like herself being

Table of Icelandic Literature and History.

		I. *The Commonwealth.* *400 years.*	
Heroic Age.	870– 930	Poetry of Western Islands.	Settlement of colonists from Western Isles and Norway.
	930– 980	Early Icelandic poets, chiefly abroad.	Constitution worked out—Events of earlier sagas take place.
	980–1030	Icelandic poets abroad.	Christianity comes in—Events of later sagas take place.
Saga Telling.	1030–1100	*First era of phonetic change.*	Peace—Ecclesiastical organization.
The Literary Age.	1100–1150	Ari and his school—Thorodd—Vernacular writing begins.	
	1150–1220	Saga-Writers—Second generation of historians.	First civil wars—1208–22—Rise of Sturlungs.
	1220–1248	Snorri and his school—Biographers.	Second civil wars, 1226–58—Fall of Great Houses.
	1248–1284	Sturla—*Second era of phonetic change.*	Change of law, 1271—Submission to Norwegian kings.
		II. *Medievalism.* *250 years.*	
Continental Influence chiefly Norse.	1284–1320	Collecting and editing—Foreign romances.	Foreign influence through Norway.
	1320–1390	Annalists—Copyists—New Medieval poetry begins.	Great eruptions, 1362 and 1389—Epidemics—Danish rule, 1380.
	1390–1413	Death of old traditions, &c.	Epidemics—Norse trade—Close of intercourse with Norway.
Dark Age.	1413–1530	Only Medieval poetry flourishes.	Isolation from Continent—English trade.
		III. *Reformation—Absolute Rule—Decay.* *320 years.*	
Reformation.	1530–1575	Odd—Printing—*Third era of phonetic change.*	Religious struggle—New organization—Hanse trade.
Renaissance.	1575–1640	First antiquarians.	Danish monopoly—Pirates' ravages.
	1640–1700	Hallgrim—Paper copies taken.	
Gradual Decay.	1700–1730	Jon Vidalin—Arni Magnusson—MSS. taken abroad.	Increasing Decay. Smallpox kills one-third population, 1707.
	1730–1768	Eggert Olafsson.	Great famine, 10,000 die, 1759—Sheep plague, 1762—Eruption, 1765.
	1768–1800	Finn Jonsson—Icelandic scholars abroad.	Great eruption, 1783.
	1800–1850	Rationalistic movement—European influences first felt.	Beginnings of recovery—Travellers make known island to Europe—Free constitution in Denmark, 1848.
		IV. *Modern Iceland.*	
Recovery of Iceland.	1850–1874	Modern thought and learning—Icelandic scholars abroad.	Increasing wealth and population—Free trade, 1854—Jon Sigurdsson and home rule struggle.
	1874		Home rule granted.

Christians), Helgi Biolan, Biorn the Eastern, Helgi the Lean, Ketil the Foolish, &c., who settled the best land in the island (west, north-west and north), and founded families who long swayed its destinies. There also came from the Western Islands a fellowship of vikings seeking a free home in the north. They had colonized the west in the viking times; they had "fought at Hafursfirth," helping their stay-at-home kinsmen against the centralization of the great head-king, who, when he had crushed opposition in Norway, followed up his victory by compelling them to flee or bow to his rule. Such were Ingimund the Old, Geirmund Hellskin, Thord Beardie (who had wed St Edmund's granddaughter,) Audun Shackle, Bryniulf the Old, Uni, to whom Harold promised the earldom of the new land if he could make the settlers acknowledge him as king (a hopeless project), and others by whom the north-west, north and east were almost completely "claimed." (3) In 900–930 a few more incomers direct from Norway completed the settlement of the south, north-east and south-east. Among them were Earl Hrollaug (half-brother of Hrolf Ganger and of the first earl of Orkney), Hialti, Hrafnkell Frey's priest, and the sons of Asbiorn. Fully three-quarters of the land was settled from the west, and among these immigrants there was no small proportion of Irish blood. In 1100 there were 4500 franklins, *i.e.* about 50,000 souls.

Organization.

The unit of Icelandic politics was the homestead with its franklin-owner (*buendi*) its primal organization the hundred-moot (*thing*), its tie the goðorð (godar) or chieftainship. The chief who had led a band of kinsmen and dependants to the new land, taken a "claim" there, and parcelled it out among them, naturally became their leader, presiding as priest at the temple feasts and sacrifices of heathen times, acting as speaker of their moot, and as their representative towards the neighbouring chiefs. He was not a feudal lord nor a local sheriff, for any franklin could change his goðorð when he would, and the rights of "judgment by peers" were in full use; moreover, the office could be bequeathed, sold, divided or pledged by the possessor; still the goði had considerable power as long as the commonwealth lasted.

Disputes between neighbouring chiefs and their clients, and uncertainty as to the law, brought about the *Constitution of Ulfliot* (*c.* 930), which appointed a central moot for the whole island, the Althing, and a speaker to speak a single "law" (principally that followed by the Gula-moot in Norway); the *Reforms of Thord Gellir* (964), settling a fixed number of moots and chieftaincies, dividing the island into four quarters (thus characterized by Ari: north, thickest settled, most famous; east, first completely settled; south, best land and greatest chiefs; west, remarkable for noble families), to each of which a head-court, the "quarter-court," was assigned; and the *Innovations of Skapti* (ascribed in the saga to Nial) *the Law-Speaker* (d. 1030), who set up a "fifth court" as the ultimate tribunal in criminal matters, and strengthened the community against the chiefs. But here constitutional growth ceased: the law-making body made few and unimportant modifications of custom; the courts were too weak for the chiefs who misused and defied them; the speaker's power was not sufficiently supported; even the ecclesiastical innovations, while they secured peace for a time, provoked in the end the struggles which put an end to the commonwealth.

Christianity was introduced *c.* 1000 from Norway. Tithes were established in 1096, and an ecclesiastical code made *c.* 1125. The first disputes about the jurisdiction of the clergy were moved by Gudmund in the 13th century, bringing on a civil war, while the questions of patronage and rights over glebe and mortmainland occupied Bishop Arni and his adversaries fifty years afterwards, when the land was under Norwegian viceroys and Norwegian law. For the civil wars broke down the great houses who had monopolized the chieftaincies; and after violent struggles (in which the Sturlungs of the first generation perished at Orlygstad, 1238, and Reykiaholt, 1241, while of the second generation Thord Kakali was called away by the king in 1250, and Thorgils Skardi slain in 1258) the submission of the island to Norway quarter after quarter took place in 1262–1264, under Gizur's auspices, and the old Common Law was replaced by the New Norse Code "Ironside" in 1271.

The political life and law of the old days is abundantly illustrated in the sagas (especially Eyrbyggia, Hensa-Thori, Reykdæla, Hrafnkell and Niala), the two collections of law-scrolls (*Codex Regius*, *c.* 1235, and *Stadarhol's Book*, *c.* 1271), the Libellus, the Liberfragments, and the Landnamabok of Ari, and the Diplomatarium. K. Maurer has made the subject his own in his *Beiträge*, *Island*, *Grágás*, &c.

The medieval Icelandic church had two bishoprics, Skalholt (S., W. and E.) 1056, and Holar (N.) 1106, and about 175 parishes (two-thirds of which belonged to the southern bishopric). They belonged to the metropolitan see of Bremen, then to Lund, lastly to Nidaros, 1237. There were several religious foundations: Thingore (founded 1133), Thwera (1155), Hitardale (*c.* 1166), Kirkby Nunnery (1184), Stad Nunnery (1296) and Saurby (*c.* 1200) were Benedictine, while Ver (1168), Flatey after Holyfell (1172), Videy (1226), Madderfield Priory (1296) and Skrid Priory (14th century) were Augustinian. The bishops, elected by the people at the Althing till 1237, enjoyed considerable power; two, Thorlak of Skalholt and John of Holar, were publicly voted saints at the Althing, and one, Gudmund, received the title of "Good" by decree of the bishop and chapter. Full details as to ecclesiastical history will be found in the *Biskupasögur* (edited by Dr. Vigfusson).

Iceland was not agricultural but pastoral, depending upon flocks and herds for subsistence, for, though rye and other grain would grow in favoured localities, the hay, self-sown, was the only regular crop. In some districts the fisheries and fowling were of importance, but nine-tenths of the population lived by their sheep and cattle. Life on each homestead was regularly portioned out: out door occupations—fishing, shepherding, fowling, and the hay-making and fuel-gathering—occupying the summer; while in door business—weaving, tool-making, &c.—filled up the long winter. The year was broken by the spring feasts and moots, the great Althing meeting at midsummer, the marriage and arval gatherings after the summer, and the long yule feasts at midwinter. There were but two degrees of men, free and unfree, though only the franklins had any political power; and, from the nature of the life, social intercourse was unrestrained and unfettered; goði and thrall lived the same lives, ate the same food, spoke the same tongue, and differed little in clothing or habits. The thrall had a house of his own and was rather villein or serf than slave, having rights and a legal price by law. During the heathen days many great chiefs passed part of their lives in Norway at the king's court, but after the establishment of Christianity in Iceland they kept more at home, visiting the continent, however, for purposes of state, suits with clergy, &c. Trade was from the first almost entirely in foreign (Norse) hands.

Mode of life.

The introduction of a church system brought little change. The great families put their members into orders, and so continued to enjoy the profits of the land which they had given to the church; the priests married and otherwise behaved like the franklins around them in everyday matters, farming, trading, going to law like laymen.

Life in the commonwealth was turbulent and anarchic, but free and varied; it produced men of mark, and fostered bravery, adventure and progress. But on the union with Norway all this ceased, and there was left but a low dead level of poor peasant proprietors careless of all save how to live by as little labour as possible, and pay as few taxes as they could to their foreign rulers. The island received a foreign governor (*Earl*, *Hirdstjori* or *Stiptamtsmadr* as he was successively called), and was parcelled out into counties (*sýslur*), administered by sheriffs (*sýslumadr*) appointed by the king. A royal court took the place of the Althing courts; the local business of the local things was carried out by the (*hreppstjori*) bailiff, a subordinate of the sheriff; and the goðorð, things, quarter-courts, trial by jury, &c., were swept away by these innovations. The power of the crown was increased by the confiscation of the great Sturlung estates, which were underleased to farmers, while the early falling off of the Norse trade threatened to deprive the island of the means of existence; for the great epidemics and eruptions of the 14th century had gravely attacked its pastoral wealth and ruined much of its pasture and fishery.

Effects of the Union.

The union of the Three Crowns transferred the practical rule of Iceland to Denmark in 1280, and the old Treaty of Union, by which the island had reserved its essential rights, was disregarded by the absolute Danish monarchs; but, though new taxation was imposed, it was rather their careless neglect than their too active interference that damaged Iceland's interests. But for an English trade, which sprang up out of the half-smuggling, half-buccaneering enterprise of the Bristol merchants, the island would have fared badly, for during the whole of the 15th century their trade with England, exporting sulphur, eiderdown (of which the English taught them the value), wool, and salt stock-fish, and importing as before wood, iron, honey, wine, grain and flax goods, was their only link with the outer world. This period of Iceland's existence is eventless: she had got peace but with few of its blessings; all spirit seemed to have died with the commonwealth; even shepherding and such agriculture as there had been sank to a lower stage; wagons, ploughs and carts went out of use and knowledge; architecture in timber became a lost art, and the fine carved and painted halls of the heathen days were replaced by turf-walled barns half sunk in the earth; the large decked luggers of the old days gave way to small undecked fishing-boats.

The Reformation in Iceland wakened men's minds, but it left their circumstances little changed. Though the fires of martyrdom were never lighted in Iceland, the story of the easily accepted Reformation is not altogether a pleasant one. When it was accomplished, the little knot of able men who came to the front did much in preserving the records of the past, while Odd and Hallgrim exhibit the noblest impulses of their time. While there was this revolution in religion a social and political revolution never came to Iceland. The Hanse trade replaced the English for the worse; and the Danish monopoly which succeeded it when the Danish kings began to act again with vigour was still less profitable. The glebes and hospital lands were a fresh power in the hands of the crown, and the subservient Lutheran clergy became the most powerful class in the island, while the system of under-leasing at rackrent and short lease with unsecured tenant right extended over at least a quarter of the better land.

The Reformation.

A new plague, that of the English, Gascon and Algerine pirates, marked the close of the 16th century and opening of the 17th, causing widespread panic and some devastation in 1579, 1613–1616 and 1627. Nothing points more to the helplessness of the natives' condition than their powerlessness against these foes. But the 18th century is the most gloomy in Iceland's annals. Smallpox, famine, sheep disease, and the eruptions of 1765 and 1783 follow each other in terrible succession. Against such visitations, which reduced the population by about a fourth, little could be done. The few literary men, whose work was done and whose books were published abroad, were only concerned with the past, and Jon Vidalin is the one man of mark, beside Eggert Olafsson, who worked and wrote for his own generation.[1]

Decadence.

Gradually the ideas which were agitating Europe spread through Scandinavia into Iceland, and its claims were more respectfully listened to. The continental system, which, by its leading to the blockade of Denmark, threatened to starve Iceland, was neutralized by special action of the British government. Trade and fishery grew a little brisker, and at length the turn came.

Modern times.

The rationalistic movement, headed by Magnus Stephenson, a patriotic, narrow-minded lawyer, did little good as far as church reform went, but was accompanied by a more successful effort to educate the people. A Useful Knowledge Society was formed and did some honest work. Newspapers and periodicals were published, and the very stir which the ecclesiastical disputes encouraged did good. When free trade came, and when the free constitution of Denmark had produced its legitimate effects, the endeavours of a few patriots such as Jon Sigurdsson were able to push on the next generation a step further. Questions of a modern political complexion arose; the cattle export controversy and the great home rule struggle began. After thirty years' agitation home rule was conceded in 1874 (see above, *Government*). (F. Y. P.)

Ancient Literature

Poetry.—Iceland has always borne a high renown for song, but has never produced a poet of the highest order, the qualities which in other lands were most sought for and admired in poetry being in Iceland lavished on the saga, a prose epic, while Icelandic poetry is to be rated very high for the one quality which its authors have ever aimed at—melody of sound. To these generalizations there are few exceptions, though Icelandic literature includes a group of poems which possess qualities of high imagination, deep pathos, fresh love of nature, passionate dramatic power, and noble simplicity of language which Icelandic poetry lacks. The solution is that these poems do not belong to Iceland at all. They are the poetry of the "Western Islands."

It was among the Scandinavian colonists of the British coasts that in the first generations after the colonization of Iceland

[1] For the periods succeeding the union, Danish state papers and the *History* of Finn Jonsson are the best authority.

therefrom a magnificent school of poetry arose, to which we owe works that for power and beauty can be paralleled in no Teutonic language till centuries after their date. To this school, which is totally distinct from the Icelandic, ran its own course apart and perished before the 13th century, the following works belong (of their authors we have scarcely a name or two; their dates can be rarely exactly fixed, but they lie between the beginning of the 9th and the end of the 10th centuries), classified into groups:—

(*a*) The *Helgi* trilogy (last third lost save a few verses, but preserved in prose in *Hromund Gripsson's Saga*), the *Raising of Anganty* and *Death of Hialmar* (in *Hervarar Saga*), the fragments of a *Volsung Lay* (*Volsungakiraða*) (part interpolated in earlier poems, part underlying the prose in *Volsunga Saga*), all by one poet, to whom Dr Vigfusson would also ascribe *Völuspá*, *Vegtamskviða*, *Þrymskviða*, *Grötta Song* and *Völundarkviða*.

(*b*) The Dramatic Poems:—*Flyting of Loki*, the *För Skirnis*, the *Harbarðslioð* and several fragments, all one man's work, to whose school belong, probably, the *Lay* underlying the story of Ivar's death in *Skioldunga Saga*.

(*c*) The Didactic Poetry:—*Grímnismál*, *Vafþruðnismál*, *Alvíssmal*, &c.

(*d*) The Genealogical and Mythological Poems:—*Hyndluljoð*, written for one of the Haurda-Kari family, so famous in the Orkneys; *Ynglingatal* and *Haustlong*, by Thiodolf of Hvin; *Rig's Thul*, &c.

(*e*) The Dirges and Battle Songs—such as that on Hafur-firth Battle *Hrafnsmal*, by Thiodolf of Hvin or Thorbjörn Hornklofi, shortly after 870; Eirik's Dirge (*Eiríksmál*) between 950 and 969; the *Dart-Lay on Clontarf Battle* (1014); *Biarka-mal* (fragments of which we have, and paraphrase of more is found in *Hrolf Kraki's Saga* and in Saxo).

There are also fragments of poems in *Half's Saga*, *Asmund Kappa-Bana's Saga*, in the Latin verses of Saxo, and the Shield Lays (*Ragnarsdrapa*) by Bragi, &c., of this school, which closes with the *Sun-Song*, a powerful Christian Dantesque poem, recalling some of the early compositions of the Irish Church, and with the 12th-century *Lay of Ragnar*, *Lay of Starkad*, *The Proverb Song* (*Havamal*) and *Krakumal*, to which we may add those singular Gloss-poems, the *Þulur*, which also belong to the Western Isles.

To Greenland, Iceland's farthest colony, founded in the 10th century, we owe the two *Lays of Atli*, and probably *Hymiskviða*, which, though of a weirder, harsher cast, yet belong to the Western Isles school and not to Iceland.

In form all these poems belong to two or three classes:—*kviða*, an epic "cantilena"; *tál*, a genealogical poem; *drapa*, songs of praise, &c., written in modifications of the old Teutonic metre which we know in Beowulf; *galdr* and *lokkr*, spell and charm songs in a more lyric measure; and *mál*, a dialogue poem, and *liod*, a lay, in elegiac measure suited to the subject.

The characteristics of this Western school are no doubt the result of the contact of Scandinavian colonists of the viking-tide, living lives of the wildest adventure, with an imaginative and civilized race, that exercised upon them a very strong and lasting influence (the effects of which were also felt in Iceland, but in a different way). The frequent intermarriages which mingled the best families of either race are sufficient proof of the close communion of Northmen and Celts in the 9th and 10th centuries, while there are in the poems themselves traces of Celtic mythology, language and manners.[1]

When one turns to the early poetry of the Scandinavian continent, preserved in the rune-staves on the memorial stones of Sweden, Norway and Denmark, in the didactic *Havamal*, the *Great Volsung Lay* (*i.e.* Sigurd II., Fafnis's Lay, Sigrdrifa's Lay) and *Hamdismal*, all continental, and all entirely consonant to the remains of Old English poetry in metre, feeling and treatment, one can see that it is with this school that the Icelandic "makers" are in sympathy, and that from it their verse naturally descends. While shrewdness, plain straightforwardness, and a certain stern way of looking at life are common to both, the Icelandic school adds a complexity of structure and ornament, an elaborate mythological and enigmatical phraseology, and a regularity of rhyme, assonance, luxuriance, quantity and syllabification, which it caught from the Latin and Celtic poets, and adapted with exquisite ingenuity to its own main object, that of securing the greatest possible beauty of sound.

[1] Many of these poems were Englished in prose by the translator of Mallet, by B. Thorpe in his *Sæmund's Edda*, and two or three by Messrs Morris and Magnussen, as appendices to their translation of *Volsunga Saga*. Earlier translations in verse are those in Dryden's *Miscellany* (vol. vi), A. Cottle's *Edda*, Mathias's *Translations*, and W. Herbert's *Old Icelandic Poetry*. Gray's versions of *Darradar-liod* and *Vegtamskviða* are well known.

The first generations of Icelandic poets resemble in many ways the later troubadours; the books of the kings and the sagas are full of their strange lives. Men of good birth (nearly always, too, of Celtic blood on one side at least), they leave Iceland young and attach themselves to the kings and earls of the north, living in their courts as their henchmen, sharing their adventures in weal and woe, praising their victories, and hymning their deaths if they did not fall by their sides—men of quick passion, unhappy in their loves, jealous of rival poets and of their own fame, ever ready to answer criticism with a satire or with a sword-thrust, but clinging through all to their art, in which they attained most marvellous skill.

Such men were Egil, the foe of Eirik Bloodaxe and the friend of Æthelstan; Kormak, the hot-headed champion; Eyvind, King Haakon's poet, called Skaldaspillir, because he copied in his dirge over that king the older and finer *Eiriksmal*; Gunnlaug, who sang at Æthelred's court, and fell at the hands of a brother bard, Hrafn; Hallfred, Olaf Tryggvason's poet, who lies in Iona by the side of Macbeth; Sighvat, Saint Olaf's henchman, most prolific of all his comrades; Thormod, Coalbrow's poet, who died singing after Sticklestad battle; Ref, Ottar the Black, Arnor the earls' poet, and, of those whose poetry was almost confined to Iceland, Gretti, Biorn the Hitdale champion, and the two model Icelandic masters, Einar Skulason and Markus the Lawman, both of the 12th century.

It is impossible to do more here than mention the names of the most famous of the long roll of poets which are noted in the works of Snorri and in the two *Skalda-tal*. They range from the rough and noble pathos of Egil, the mystic obscurity of Kormak, the pride and grief of Hallfred, and the marvellous fluency of Sighvat, to the florid intricacy of Einar and Markus.

The art of poetry stood to the Icelanders in lieu of music; scarcely any prominent man but knew how to turn a mocking or laudatory stanza, and down to the fall of the commonwealth the accomplishment was in high request. In the literary age the chief poets belong to the great Sturlung family, Snorri and his two nephews, Sturla and Olaf, the White Poet, being the most famous "makers" of their day. Indeed, it is in Snorri's *Edda*, a poetic grammar of a very perfect kind, that the best examples of the whole of northern poetry are to be found. The last part, *Hattatal*, a treatise on metre, was written for Earl Skuli about 1222, in imitation of Earl Rognvald and Hall's *Hattalykill* (*Clavis metrica*) of 1150. The second part, *Skaldskapar-mal*, a gradus of synonyms and epithets, which contains over 240 quotations from 65 poets, and 10 anonymous lays—a treasury of verse—was composed *c.* 1230. The first part, an exquisite sketch of northern mythology, *Gylfa-ginning*, was probably prefixed to the whole later. There is some of Sturla's poetry in his *Islendinga Saga*, and verses of Snorri occur in the *Grammatical Treatise* on figures of speech, &c., of Olaf, which contains about one hundred and forty quotations from various authors, and was written about 1250.

Besides those sources, the *Kings' Lives* of Snorri and later authors contain a great deal of verse by Icelandic poets. King Harold Sigurdsson, who fell at Stamford Bridge 1066, was both a good critic and composed himself. Many tales are told of him and his poet visitors and henchmen. The Icelandic sagas also comprise much verse which is partly genuine, partly the work of the 12th and 13th century editors. Thus there are genuine pieces in *Nial's Saga* (chaps. 34, 78, 103, 126, 146), in *Eyrbyggia*, *Laxdæla*, *Egil's Saga* (part only), *Grettla* (two and a half stanzas, cf. *Landnámabók*), *Biorn's Saga*, *Gunnlaug's Saga*, *Havard's Saga*, *Kormak's Saga*, *Viga-Glum's Saga*, *Erik the Red's Saga* and *Fostbrædra Saga*. In *Nial's*, *Gisli's* and *Droplaug's Sons' Sagas* there is good verse of a later poet, and in many sagas worthless rubbish foisted in as ornamental.

To these may be added two or three works of a semi-literary kind, composed by learned men, not by heroes and warriors. Such are *Konunga-tál*, *Hugsvinnsmál* (a paraphrase of Cato's
